Concerning results there appears to be little to sa except that the air at the highest latitudes and eve well south may by ordinary standards be judged o this showing to be virtually sterile in winter—as wa perhaps to be expected in view of the great distanc almost any disseminules would have to travel whe frozen conditions obtained and snow covered mo areas for 2,000 miles or more southward from th Pole. Nevertheless, it was a point worth demonstrating in view of the very wide dissemination foun or postulated in other circumstances elsewhere, an it is hoped that it may still be possible later on t carry out a full summer repetition of this work i order to determine more of the situation at tha season.

It may be noted that the electrostatic sampler an filters gave usually very different results, which wer in most of the present instances much higher in th latter case, sometimes by more than ten times, an that there is again some correlation between biota an air-masses, as can be seen by comparing the number given in the second table[6] with the computed source and extents of the air-masses in which we were flying Thus whereas a 'lumping' of methods and group gives an average of 1·49 bacterial plus fungal colonie per cubic foot for the March 28 'abort', during whic we were flying mainly in Pacific-maritime air "wit trajectory over Kamchatka, east Siberia and interio Alaska", a similar lumping of the colonies obtaine from the entire North Pole flight which was starte on the following day in air of relatively unfavourable northern origin gives a figure of 0·496. It is interesting to note that the only at all high figures wer obtained on the former flight, and the only ones o the polar flight that really approached them wer either from exposures made near the beginning (whe we may quite likely have been flying in air o relatively favourable origin) or at the very highes latitudes (where the air was much mixed and whe the above-mentioned pollen grain and spores appea to have been trapped). The only slide observed i some weeks of searching to have two pollen grain upon it was exposed on the return flight from th Pole about the north coast of Alaska where ther may have been a mixing of air of a relatively souther source, although this is not borne out by the bacteria and fungal colonies observed via the electrostati sampler and filters; however, it should be noted tha its fellow was the only slide from either flight whic was observed on direct microscopic examination t have more than two fungal spores upon it (it ha four), which suggests an airborne patchiness such a we have met before.

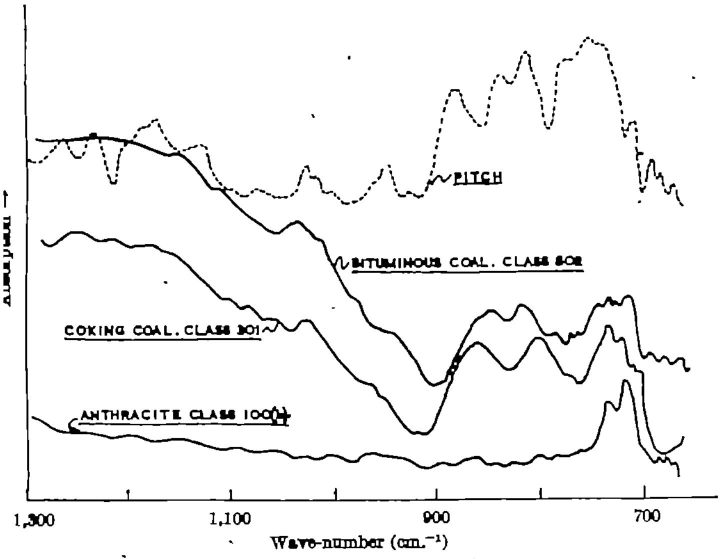
Infra-Red Spectra of Coals

Cannon and Sutherland have reported attempts to tain infra-red absorption spectra of coals, first by amining thin slices of coal[1] and, secondly, by dis- rsing the finely ground coal in 'Nujol' (liquid raffin)[2]. Using the latter technique, they found it as essential to grind the coal to a particle-size of s than one micron before successful spectra could obtained. Their examination was limited to the equency-region 1,000–10,000 cm.$^{-1}$.

We have found that thin slices of coal and dry inding of coal are both unsatisfactory. Satisfactory ectra have been obtained by the technique of inding 1 gm. of coal together with 4 ml. of 'Nujol' r 18 hr. in a power-driven agate pestle and mortar. his suspension, in which 80 per cent of the coal articles were less than 1 micron in size, was used for reparing a cell with a layer thickness of 0·05 mm. nergy transmission was low, due to scattering of e incident radiation by reflexion from the particle rfaces, so that large slit-widths were necessary. o compensate for this scattering, backgrounds were repared using a suspension of spectroscopic carbon n 'Nujol', prepared as for coal.



Infra-red spectra of coals and pitch

The infra-red absorption spectra (see illustration) f three coals (all of ash content less than 1 per cent) nd of a low melting point pitch were obtained, over he frequency-range 750–1,300 cm.$^{-1}$, using a Grubb arsons single-beam spectrometer. The pitch was elted on a heated rock-salt window to give a niformly thick film.

The anthracite gives a spectrum differing consider- bly from those of the other two coals. It is interest- ng to note that organic groupings which occur in itch also occur in coal.

No attempt has been made to assign organic roups to the absorption peaks recorded. An extensive programme is in progress for the further elucidation of these spectra.

Nature of the Solution obtained by Pyridine Extraction of Coal

In a recent communication on the internal surface of coal[1], Dryden has directed attention to the interesting agreement between (*a*) the minimum particle-size observed by Nagelschmidt and Cartwright[2] in electron micrographs of films deposited from dilute ethylenediamine extracts from coal, (*b*) particle-sizes observed in the ultramicroscopic examination of similar extracts[3], and (*c*) the order of particle-size concerned in the model of colloidal structure of coal suggested by Bangham *et al.*[4].

The solutions obtained by the pyridine extraction of coal are commonly believed to be, like the ethylenediamine extracts, essentially colloidal dispersions. Nevertheless, the average molecular weights of the substances present in such solutions are only of the order of 500–1,400, and are inconsistent with their supposed colloidal nature[5].

We have found that electron micrographs of the films formed by the evaporation of diluted pyridine extracts were almost identical in appearance with those described by Nagelschmidt and Cartwright. Examination of the particles by electron diffraction gave diffuse patterns only, resembling those for collodion; and we had therefore interpreted our electron micrographs as being merely an extension to smaller dimensions of similar but grosser aggregation phenomena observable by optical microscopy.

We have now further examined our pyridine extract solutions. Samples of the diluted pyridine solution of a coal extract ($\beta + \gamma$ fraction) and of its chloroform-soluble components (γ fraction) were spread on a glass slide and the solvent eliminated by rapid heating to 180–200° C. in a stream of nitrogen. The specimens were then kept under a vacuum of 10^{-2} cm. of mercury for about one hour. The deposits thus formed were collected on collodion, or 'Formvar', by stripping off a film cast over the deposit. The structure previously observed with the deposits disappeared as a result of this treatment. Typical electron micrographs are shown in Figs. 1, 2 and 3. The cracked portions of the films were chosen to illustrate the varnish-like appearance of the deposit. Fig. 4 shows an intermediate stage in the deposition of the material, illustrating the melting of the aggregates observed in earlier photographs. There was no evidence of the presence in the material of discrete particles.

It would have been interesting if Nagelschmidt and Cartwright had made some comment on the behaviour

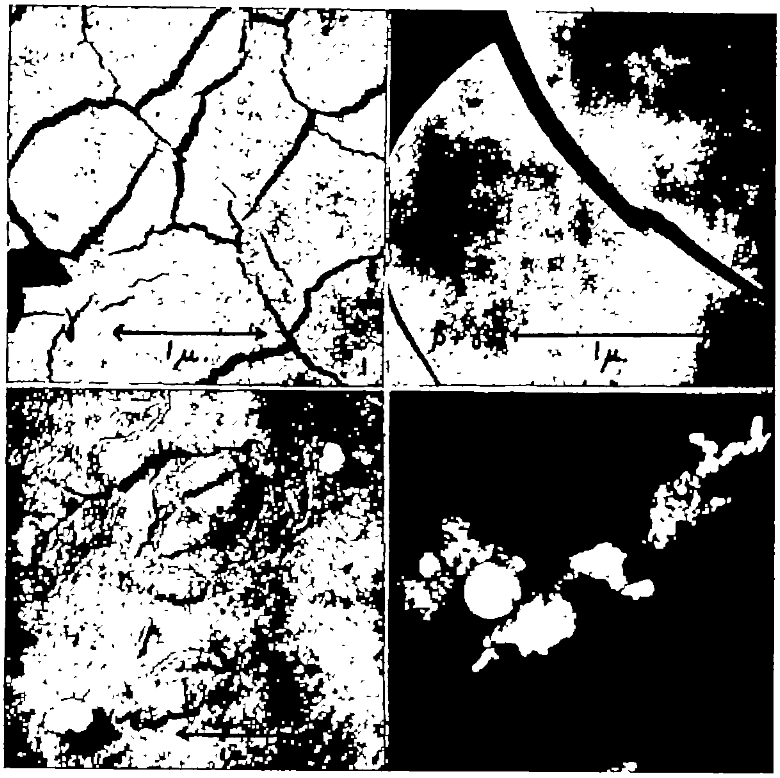

Fig. 1. γ extract: coal, 0.942. Heated to 200° C. in nitrogen
Fig. 2. β + γ extract: coal, 0.942. Heated to 200° C. in nitrogen
Fig. 3. As Fig. 1. Gold shadowed, 45°
Fig. 4. Specimen as Fig. 1. Partly fused

of their material under electron diffraction, since the particles are of suitable size for this technique with the *E.M.*3 instrument. Resolution of the particle structure by this means might be difficult (compare the X-ray studies of soap micelles by P. A. Thiessen *et al.*[6]); but the diffraction pattern could probably be distinguished from that of the 'Formvar' substrate.

A fuller account of the work will be published elsewhere.

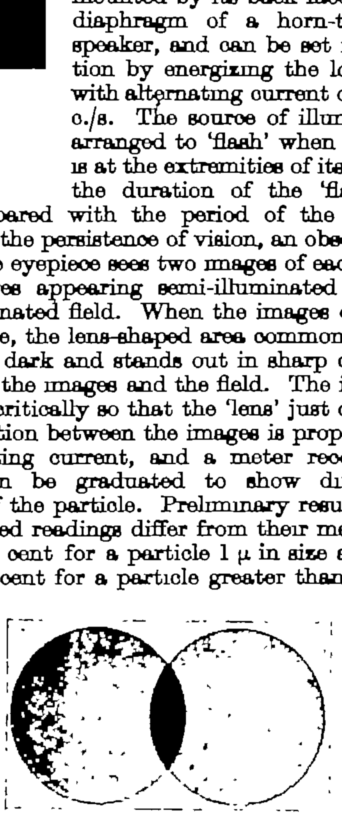
A Method of Measuring and Grading Microscopic Spherical Particles

The study of particulate matter such as dust often entails either the measurement of the individual diameters of small spherical particles viewed through a microscope, or the determination of the size distribution of such particles by counting the numbers having diameters lying within specified ranges. The conventional methods of performing these operations have not proved sufficiently accurate for some investigations being undertaken at this Unit, and a new instrument has been devised for the purpose.

The principle of the instrument consists of producing two identical coplanar images of each particle the centres of which are separated by a variable distance. The separation between the centres when the two images are arranged to touch is equal to the diameter of the images. The two images can be formed in various ways. The method described here, besides providing critical adjustment for accurate measurement of the individual diameters, also allows adaptation for rapid grading by size of the particles.

The practical arrangement consists of a normal microscope optical system, modified by the introduction of a small mirror inclined at 45° to the vertical to reflect the light beam from the objective into a horizontal eyepiece. The mirror is mounted by its back face on to the diaphragm of a horn-type loud-speaker, and can be set into vibration by energizing the loudspeaker with alternating current of about 50 c./s. The source of illumination is arranged to 'flash' when the mirror is at the extremities of its vibration, the duration of the 'flash' being short compared with the period of the vibration. Because of the persistence of vision, an observer looking into the eyepiece sees two images of each particle, these images appearing semi-illuminated against a fully illuminated field. When the images overlap, as in the figure, the lens-shaped area common to both is completely dark and stands out in sharp contrast to the rest of the images and the field. The instrument can be set critically so that the 'lens' just disappears. The separation between the images is proportional to the energizing current, and a meter recording the current can be graduated to show directly the diameter of the particle. Preliminary results suggest that repeated readings differ from their mean by less than 3 per cent for a particle 1 μ in size and by less than 1 per cent for a particle greater than 10 μ.



The following methods for grading the particles into size-groups eliminate the recording of each individual value. In the first method it is arranged that, after adjustment of the continuously variable separation has been made, the energizing current is discriminated by amplitude and an appropriate counter triggered. In the second method the energizing current is modulated by a low-frequency uare wave. For odd half-cycles of the modulating .ve the value of the current corresponds to the ver limit of a size-range, and for even half-cycles the upper limit of the range. The images of particles thin the size-range can be distinguished from others the field of view by their characteristic feature of erlapping during odd half-cycles and not overpping during even half-cycles. The images of rticles smaller than the lower limit do not overlap ring either half-cycle, while the images of particles ger than the upper limit overlap all the time. switch enables each size-range with a corresponding unter to be selected in turn. Each time a particle th the characteristic feature mentioned above is en, a triggering pulse (initiated by a foot switch) routed to the counter appropriate to the size-range.

Interaction of Macromolecules and Fibrinogen

RICKETTS[1] has described an interaction between ·xtran and fibrinogen. It was therefore decided to vestigate the interaction of several other polymers, sed in transfusion therapy, with fibrinogen of human id bovine origin.

Dextran fractions of intrinsic viscosities 0·41, 0·31, 24 and 0·06, and possessing branching factors (ratios α 1–6 glucosidic linkage to α 1–4 glucosidic linkage) arying from 4 : 1 to 11 : 1 were used. A commercial eparation of polyvinylpyrrolidone, gum acacia in line, and a hydrolysed laminarin fraction of trinsic viscosity 0·2, were also investigated.

Solutions containing 1·5, 3·0 and 6·0 per cent of ie polymers in 0·9 per cent saline were each added equal volumes of solutions containing 0·4, 0·8 and ·6 per cent of fibrinogen also in 0·9 per cent saline. he tests were made under the following conditions.

(1) *Solutions mixed at 25° C. and then placed in a frigerator at* 4° *C. for* 16 *hr.* All the dextran fractions, ith the exception of the one of intrinsic viscosity ·06, gave a precipitate. Polyvinylpyrrolidone, minarin and gum saline gave precipitates of similar agnitude to the dextran fractions of intrinsic iscosity 0·41 and 0·24. The amount of precipitate as greater with increasing concentrations of both brinogen and polymer.

(2) *Solutions mixed at* 37° *C. and then placed in an icubator at* 37° *C. for* 16 *hr.* Only laminarin formed n insoluble complex at this temperature; but when ie temperature of the remaining solutions was wered to 4° C., precipitation of the complex took lace with each of the other polymers.

Dilutions of the polymers at concentrations 0·75, ·5 and 3 per cent were made at 37° C. in plasma. n aliquot was incubated at 37° C. during 8 hr. and nother at 4° C. during a similar period. No precipitation occurred with any polymer at either mperature. However, complex formation did take lace in a 5 per cent albumin solution containing per cent sodium citrate, 0·9 per cent saline and ·4 per cent fibrinogen, the reaction being carried ut as in method (1). This indicates that it is not ıst simple solubility in citrate or albumin which is reventing the formation of the complex. The dextran–fibrinogen complex was prepared on a larger scale and injected intravenously into mice at a dose-level of 300 mgm. per kgm. of body-weight. None of the mice showed any untoward reaction.

It is well known that dextran fractions above a certain critical molecular size, namely, 59,000, increase the sedimentation-rate of erythrocytes[2]. Solutions containing 1 and 2 per cent of dextran (intrinsic viscosity 0·31) were made in a 5 per cent albumin solution. Red blood cells, washed free from plasma with saline, were added to this solution; the erythrocyte sedimentation-rate in the albumin–dextran solution was of the same order of magnitude as that of blood containing a similar dextran concentration. Hence the removal of fibrinogen had not affected the sedimentation-rate of erythrocytes. The electrophoretic pattern of plasma containing dextran is being examined to see if it is possible to detect any evidence of a soluble dextran–fibrinogen complex.

These preliminary investigations indicate that the property of forming a complex with fibrinogen is not peculiar to dextran but is also possessed by polyvinylpyrrolidone, gum acacia and laminarin, and since the complex formed contains only approximately 1 per cent of the polymer in solution and 10 per cent of fibrinogen, it probably would have no pathological significance.

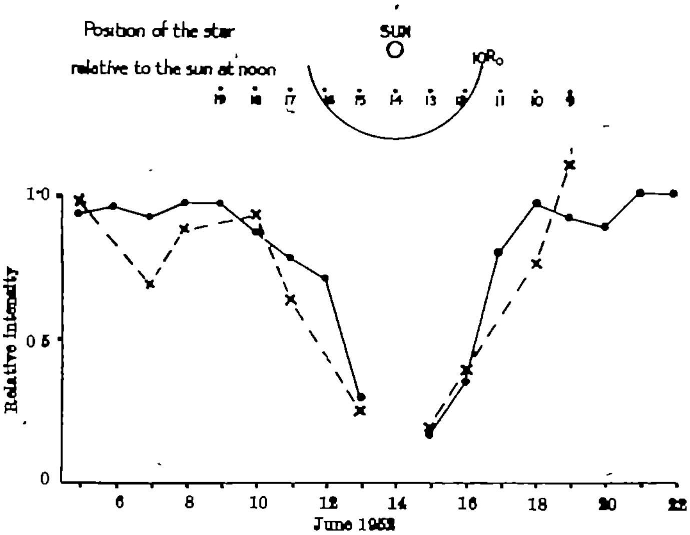
Occultation of a Radio Star by the Solar Corona

IT has been suggested[1] that the radiation from a radio star might be cut off by refraction in the solar corona, even when the angular separation of the sun and the star is several times the angular radius of the visible disk ($R_{\odot}$). The existing data on the coronal electron density have been used for predicting the effective radius of the sun for occultation on various frequencies[1]. Link[2] has calculated the circumstances of the occultation for 1952 and has also shown that the observed intensity of the radiation from the radio star should increase before the actual occultation. Attempts were made to observe these effects in June 1950 and 1951 when the radio star in Taurus (05·01) passed within an angular distance of about 4·5 $R_{\odot}$ from the sun's centre, but intense sunspot radiation prevented any useful results being obtained.

Measurements of the intensity of the radio star 05·01 were again made on frequencies of 210, 81·5 and 38 Mc./s. during the period June 5–20, 1952; as in the earlier observations, interferometers of large resolving power were used for reducing the amplitude of the record from the undisturbed sun. In addition, the position of the star was measured each day on 81·5 Mc./s.

No accurate observations were possible on 210 Mc./s., owing to the disturbing effect of a small sunspot; but reliable results were obtained on both 81·5 and 38 Mc./s. throughout most of the period. The results of the intensity measurements are shown in the accompanying graph. The measurements on 38 Mc./s. were less accurate than those on 81·5 Mc./s., due to the limited angular discrimination of the aerial system.



●—●—, 81·5 Mc./s. ; ×—×—, 38 Mc./s.

Apparent intensity of the radio star in Taurus as it passed near the sun's southern limb

It was predicted that on 38 Mc./s. a well-defined occultation should occur at a separation of about 5·2 $R_☉$, little effect being observable on 81·5 Mc./s. However, as shown by the graph, a decrease of amplitude of record occurred on both frequencies, even when the separation was as great as 10 $R_☉$. The position measurements (which were possible on all days except June 13, 14 and 15) showed no deviation greater than 2′ of arc.

The observed reduction in amplitude of the records could imply an actual reduction in flux density at the earth. On the other hand, since interferometers of considerable resolving power were used, it is possible that the reduction was due to an apparent increase in the angular diameter of the star. Such an increase in diameter might be caused by irregularities of electron density in the outer corona between 4 and 10 $R_☉$. The observations at 38 Mc./s. would be consistent with a source the apparent diameter of which increased from about 15′ of arc when the separation was 10 $R_☉$, to about 45′ of arc at 4·5 $R_☉$. On 81·5 Mc./s. the corresponding figures are 8′ and 25′.

The interpretation of these results in terms of the structure of the outer solar corona will be considered in a separate paper.

This work was carried out as part of a programme of radio research at the Cavendish Laboratory, supported by the Department of Scientific and Industrial Research. One of us (F. G. S.) is indebted to the Royal Commission for the Exhibition of 1851 for a senior studentship.

Heats of Formation of Mercury Dimethyl, Diethyl and Diphenyl and some Associated Bond Dissociation Energies

THE values obtained by Berthelot[1] for the heats o formation of some of the organic compounds o mercury have been in doubt for some time. A re-examination of these compounds is especially important, since their heats of formation can be combined with other recent thermochemical data to give the mean bond energy of the C—Hg bond and the heats of formation of various alkyl and aryl halides. The values fo the halides throw considerable light on C—halogen bond dissociation energies and the C—H dissociation energy in benzene.

The problem was approached through the heat of combustion of mercury dimethyl, diethyl and diphenyl, and in every case a result was obtained which differed appreciably from that of Berthelot.

The materials were prepared by the method of Gilman[2] and, in the case o the liquids, carefully purified by repeated fractionation. The mercury diphenyl was purified by recrystallization from methanol.

The liquids were distilled under high vacuum into thin-walled glass capsules which were then sealed. The solid diphenyl was compressed into pellets. Combustion was carried out in a stainless steel bomb and, since incomplete combustion to the extent o 1–2 per cent was observed, the products of combustion were analysed and the calculation of results based on the weight of carbon dioxide found. Appreciable amounts of mercuric oxide were also present and these were estimated and a correction made. The following values have been obtained for the heat o formation of the mercury compounds :

$$Q_f(\mathrm{Hg(CH_3)_2},\ l) = -14{\cdot}3 \pm 0{\cdot}1 \text{ k.cal./mole.}$$

This is markedly different from Berthelot's result o − 36·8 k.cal/mole, but agrees excellently with the value − 14·31 ± 1·85 k.cal./mole derived by Skinner and his co-workers, from a thermochemical study o the reactions of mercury dimethyl with alcoholic solutions of halogens and mercuric halides :

$$Q_f(\mathrm{Hg(C_2H_5)_2},\ l) = -6{\cdot}5 \pm 0{\cdot}2 \text{ k.cal./mole.}$$

This again disagrees with Berthelot (− 15·7 k.cal./ mole) but is much closer to the Skinner[4] value o − 9·9 ± 1·7 k.cal./mole, especially if the estimated error is taken into account.

$$Q_f(\mathrm{Hg(C_6H_5)_2},\ c) = -71{\cdot}6 \pm 0{\cdot}3 \text{ k.cal./mole.}$$

Berthelot's value is − 92·1 k.cal./mole. Skinner quotes two values, − 67·1 ± 3 and − 56·5 ± k.cal./mole, the large difference being due to considerable uncertainty as to the correct value for the heat of formation of phenyl bromide. The thermochemical data obtained by Skinner *et al.*[3,4] can be combined with our values for the heat of formation of the mercury compounds to give the following results :

$Q_f(\mathrm{CH_3Br},\ g) = 8{\cdot}6$ k.cal./mole $\qquad Q_f(\mathrm{CH_3I},\ l) = 2{\cdot}3$ k.cal./mol
$Q_f(\mathrm{C_2H_5Br},\ l) = 22{\cdot}1$ „ $\qquad Q_f(\mathrm{C_2H_5I},\ l) = 10{\cdot}13$ „
$Q_f(\mathrm{C_6H_5Br},\ l) = -16{\cdot}3$ „ $\qquad Q_f(\mathrm{C_6H_5I},\ l) = -28{\cdot}8$ „

From these values, knowing the C—H dissociation energy in the hydrocarbon, the following C—halogen bond-dissociation energies may be found :

$(CH_3 - Br) = 67{\cdot}8$ k.cal./mole $D(CH_3 - I) = 53{\cdot}4$ k.cal./mole
$(C_6H_5 - Br) = 66{\cdot}5$ ″ $D(C_6H_5 - I) = 52{\cdot}6$ ″

ı view of the possible errors in the assumed data, e feel that the above dissociation energies are subject) an uncertainty of about ± 2 k.cal./mole.

Butler and Polanyi[5] have measured the C—I ıssociation energy in phenyl iodide by means of yrolytic decomposition. Szwarc[6] has repeated this ork and obtained a higher value. Also, Szwarc and Villiams[7] have found the C—Br dissociation energy ı phenyl bromide.

From these results and the heats of formation of aseous phenyl iodide, phenyl bromide and benzene, ıe heat of formation of the phenyl radical and the —H dissociation energy in benzene may be derived.

—hal. dissociation energy in k.cal./mole		$Q_f(C_6H_5)$ in k cal /mole	$D(C_6H_5 - H)$ in k cal /mole
(Ph − I) ∼ 55	(ref. 5)	∼ − 67·9	∼ 100
(Ph − I) > 57	(ref. 6)	∼ − 70	∼ 102
(Ph − Br) = 70·9	(ref. 7)	− 60·7	102

Finally, the measured heats of formation enable s to calculate the sum of the Hg—C dissociation ıergies in the compounds investigated:

$D(Hg - Me_2) = 57{\cdot}1 \pm 2$ k.cal./mole
$D(Hg - Et_2) = 48{\cdot}5$ k.cal./mole
$D(Hg - Ph_2) = 60$ ″ } limits of error uncertain

We should like to add that our experimental results ɔuld not have been extended so widely but for the aluable work carried out on the thermochemistry f these mercury compounds by Skinner and his o-workers in Manchester.

Precursors of Protoporphyrin in *Chlorella*

ON the basis of studies of *Chlorella* mutants a ıiosynthetic chain has been formulated leading from ırotoporphyrin through Mg protoporphyrin, Mg ·inyl pheoporphyrin and protochlorophyll finally o chlorophyll[1]. We have recently isolated a *Chlorella* nutant which promises to reveal some of the precursor ›orphyrins leading up to protoporphyrin.

This mutant, W_5B-17, arose from an irradiation vith ultra-violet light of the protoporphyrin-pro‑lucing W_5B cells. The W_5B-17 cells appear almost olourless or pale brown. On solid medium they leak ·ut porphyrins which are more soluble than proto‑›orphyrin and discolour the agar pink. It has been ound possible to grow this mutant in liquid culture vithout diminishing the pigment yield. Starting vith a colourless medium, by the end of the week he medium turns a deep chocolate-brown colour due o the accumulation of porphyrins produced by the nutant. From fifteen litres of medium it is estimated hat a total of approximately 1·5 gm. of porphyrins s produced.

Preliminary studies of the porphyrins from this nutant indicate that it consists of a number of com‑›onents. From the R_F values of the paper chromato‑rams[2] it is concluded that there are present, in this nixture, porphyrins containing 2, 3, 4, 5 and possibly 8 carboxyls. The fraction containing two carboxyl groups per molecule represents most of the porphyrin produced: it consists of protoporphyrin and two additional main porphyrin components. One of these main components may be an immediate precursor of protoporphyrin since its absorption spectrum indicates that it contains one vinyl group in contrast to the two vinyl groups of protoporphyrin.

In the past, workers who have attempted a study of porphyrin precursors have been limited in material primarily to the porphyrins excreted by patients with some metabolic lesion in their porphyrin metabolism. Such studies have been difficult because the disease is rare, the isolation of the pigments tedious and the yields small. This new mutant now makes available unlimited quantities of several of the protoporphyrin precursors. It is hoped that studies on this alga will not only provide information on the important biosynthetic chain of heme and chlorophyll but also may eventually contribute to an understanding of porphyrinuric diseases in man.

Structure of Lanostenol

RECENTLY, the molecular structure of lanostadienol (lanosterol), $C_{30}H_{50}O$, an important 'triterpenoid' constituent of wool-wax, has been studied intensively. Ruzicka *et al.*[1] and Barton, McGhie *et al.*[2] have suggested three possible formulæ and, considering the evidence available, were unable to decide between them. Earlier, we had begun an X-ray structure analysis to provide unequivocal proof of the molecular structure of lanostadienol. This investigation has provided, in addition, a complete description of the stereochemistry of the molecule, avoiding the complex orthodox methods of stereochemistry. From earlier work, lanostadienol is known to contain four rings, one inert double-bond and one active double bond in the terminal *iso*propylidene group of the long side-chain. Hydrogenation of the active double-bond yields lanostenol, and the iodoacetate of this compound[3] was selected as a suitable 'heavy-atom' derivative for the structure analysis.

The crystals of lanostenol iodoacetate, $C_{32}H_{53}O_2I$, are orthorhombic, the space group being $P2_12_12_1$. There are four molecules in the unit-cell of dimensions. $a = 7{\cdot}6$, $b = 10{\cdot}9$, $c = 38{\cdot}6$ A. The x, y and z parameters of the iodine atoms were determined from Patterson F^2 syntheses of the projections along the a and b axes. The first Fourier syntheses, $\rho\ (0yz)$ and $\rho\ (x0z)$ were computed with the majority of signs fixed by the contributions of the iodine atoms, and from these electron-density distributions the general disposition of the molecule in the unit cell was evident. Due to the existence of false peaks adjacent to the iodine atoms, the initial difficulty in solving the structure was the location of the acetate group. However, after testing various molecular models, the detailed configuration of the molecule was achieved, refinement proceeding by successive Fourier syntheses until the reliability factors, $\frac{\Sigma \mid F_o - F_c \mid}{\Sigma \mid F_o \mid}$, were reduced to 22 and 25 per cent

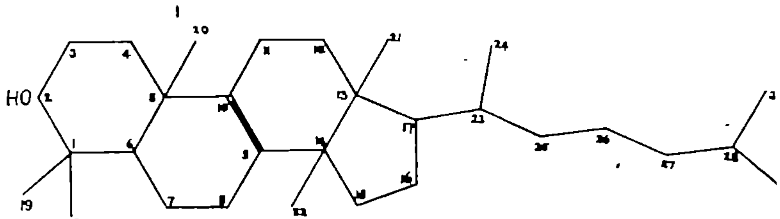

Fig. 2. Formal representation of the molecule

for the 0*kl* and *h*0*l* sets of reflexions respectively. A section of the electron-density distribution projected on the *bc* plane and selected to display one complete molecule is shown in Fig. 1,*a*. The corresponding diagram of the molecule is given in Fig. 1,*b*. The *b* axis projection (not shown here) provides a relatively clear picture of the molecule viewed approximately side-on to its main length. The combined information in the two projections provides a precise determination of the molecular structure and stereochemistry of lanostenol.

The formal representation of the chemical structure of lanostenol is given in Fig. 2, the ring skeleton consisting of three six-membered rings and one five-membered ring fused in a manner similar to that observed in cholesterol. The rings *A*/*B* and *C*/*D* are *trans*-fused, with the presence of the inert double-bond at C(9)–C(10) deduced from the distortion of the *B*/*C* ring system apparent in Fig. 1,*a*. Due to the presence of the double-bond at C(9)–C(10) the ring system *B*/*C* should be symmetrical; but the fusion of the five-membered ring *D* to the six-membered ring *C* distorts the latter (see Figs. 1,*a* and *b*). The *gem*-dimethyl group C(18), C(19) is attached to C(1), while single angular methyl groups C(20), C(21) and C(22) are attached to C(5), C(13) and C(14) respectively. The *iso*-octane chain is attached by C(23) to C(17) of ring *D*.

The molecular structure, determined by this method, is in agreement with the partial formula of McGhie *et al.*[4] and Barton *et al.*[5] for the ring system

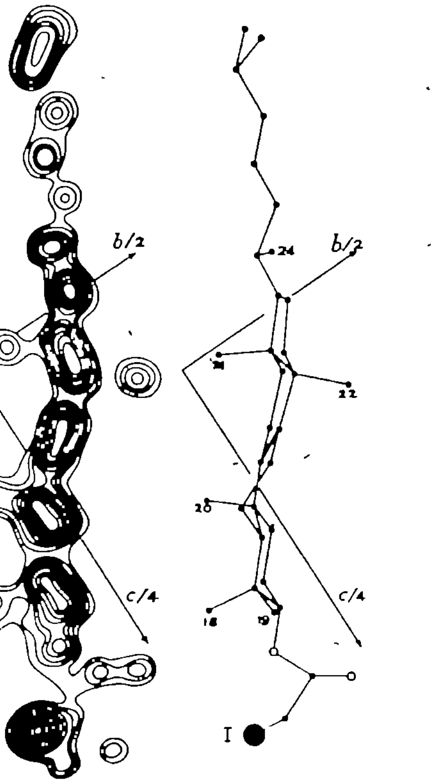

Fig. 1. (*a*) Part of the *a*-axis projection of electron-density distribution, illustrating one molecule. (*b*) Corresponding diagram of the molecule. The double-bond at C(9)—C(10) is shown as a thicker line

A/*B*/*C* and their associated methyl groups, but di proves their suggestion that ring *D* is six-membere In a series of papers[6] on chemical and spectr photometric studies, Ruzicka *et al.* gave structur evidence which agrees with that of Barton *et al.*[5] an McGhie *et al.*[4] regarding the part of the molecule u to ring *C*; in addition, they determined the structu of the long side-chain[7]. In their latest publication Ruzicka *et al.* have proposed a structural formul in which ring *D* is five-membered; but there are thr possible molecular structures, depending on wheth C(23) is linked to C(15), C(16) or C(17). Barton *et al* have obtained supporting evidence for the bas correctness of Ruzicka's[1] structures; but, on the bas of the 'isoprene' rule, they select the point of attac ment of C(23) as C(15) or C(16). From our analysis, has been made clear that the point of linkage is C(17

The structural formula for lanostenol cannot b fitted to the 'isoprene' rule which normally applie to triterpenes. It is of interest in this connexio that this compound co-exists with cholesterol in woo wax and with ergosterol in yeast. The question ther fore arises as to whether lanostenol and the relate compounds with the same carbon skeleton, lanc stadienol, agnostadienol and agnostatrienol, shoul be considered triterpenes or trimethylated sterols.

A more detailed report of the structure analysi and of the stereochemistry of the molecule will b given at a later date.

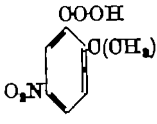
Steric Effect of the tert.-Butyl Group

WHEN *tert.*-butylbenzene is mono-nitrated th main product is the *para* isomer; but toluene give largely the *ortho*[1-3]. Again, when *p*-*tert.*-butyltoluene i dinitrated, 4-*tert.*-butyl-2 : 6-dinitrotoluene is formed Substitution *ortho* to the *tert.*-butyl group is clearl hindered by the steric effect of this large group[1,2].

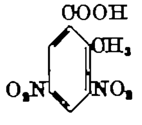
On dinitration of *tert.*-butylbenzene with fuming tric acid[5] or warm mixed acid[6], the product is : 4-dinitro-*tert.*-butylbenzene. Still further nitration ves a trinitro product of unknown orientation[6]. is possible from what follows that this may not 2 : 4 : 6-*tert.*-butylbenzene.

It has now been observed that *o-tert.*-butylbenzoic id can readily be nitrated with nitric acid to give *tert.*-butyl-5-nitrobenzoic acid (I) as colourless eedles (m.p. 170° C.); but further nitration of this id or its ethyl ester with fuming nitric acid cannot accomplished, nor is bromination by the powerful ethod of Derbyshire and Waters[7] effective.

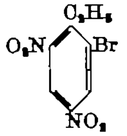
It is clear that in (I) and probably also in 2 : 4-nitro-*tert.*-butylbenzene there is considerable resistance to the entry *ortho* to the *tert.*-butyl group of a cond substituent. No such difficulty occurs with e methyl group, for *o*-toluic acid on nitration gives mixture of the 3- and 5- mono-nitro products, ther of which on further nitration yields 3 : 5-di-itro-2-toluic acid (II)[8]. Nor is 2 : 6-substitution round the ethyl group difficult, for it has been noted at 2 : 4-dinitroethylbenzene is smoothly brominated y the Derbyshire and Waters method to give -bromo-4 : 6-dinitroethylbenzene (III) as a golden-ellow oil (b.p. 190° C. at 15 mm.).



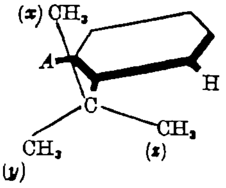
(I)



(II)



(III)



(IV)

It is scarcely to be expected that, if one group can nter *ortho* to the *tert.*-butyl group, another of roughly qual size cannot enter the second *ortho* position. he deactivating effect of the first group can scarcely e very important, for it has been pointed out that itro[9] and probably carboxyl[10] next to large groups re not coplanar with the ring and therefore will xert much smaller electromeric effects.

Some dissymmetry of the *tert.*-butyl group is im-lied. Bending of the C_{ar}–C_{al} bond comes first to ind, but a more likely explanation is possible if he *tert.*-butyl group is likened to a 'blown-out' mbrella. The *ortho* group (*A* in IV) will fit nicely etween two spokes of the umbrella (methyl groups and *y*) but the third spoke (methyl group *z*) will roject towards the other *ortho* position, so inhibiting ffectively the entry of a second *ortho* substituent. Methyl, of course, has the same shape as *tert.*-butyl, ut is obviously too small to block the second *ortho* osition.

Insufficient is known about the transition state in romatic electrophilic substitution to say whether he projecting methyl group acts by preventing the *rtho* hydrogen atom from taking up the position or ejection or by blocking the approach of the ttacking cation.

A fuller description of the new compounds mentioned, together with others, will be given elsewhere. One of us (F. H. C. S.) is indebted to the Ministry of Education for Northern Ireland for a grant.

Mollusc Control and Fish-Farming in Central Africa

IN Africa, fish-ponds and other waters may easily become infested with large numbers of different snails, including the intermediate hosts of bilharzia[1].

This problem is always kept in mind[2], as well as the objections of medical people and others against large-scale fish-farming over wide areas; but in many places fish-farming is the only possibility of providing the natives with animal proteins. Mollusc control must therefore be worked out without interference with the production of fish, and such methods as the use of molluscicides (copper salts and other antibiotics) have to be avoided[3]. There remains biological control; but this also has its difficulties. There is the possibility of using birds, for example, ducks[4], or amphibians; but fishes only will be dealt with here.

Many mollusc-eating fishes are already known in Africa, for example, *Astatoreochromis alluaudi*, *Synodontis* sp.[5], *Clarias gariepinus*[1], etc.; but they are not yet used in ponds so their practical value remains uncertain.

Work done at this station on a local cichlid, *Serranochromis* sp. (presumably *S. macrocephala*), has given valuable information on snail control. Although the study of the feeding habits of this fish is not yet completed, the data already obtained are worth considering.

In rivers, this fish eats, among other organisms, different species of snails (58 per cent of thirty-five fishes examined). Since the shells are broken, it is often difficult to determine exactly which are the species involved; but we have been able to recognize Planorbidæ, Ancylidæ and Melaniidæ.

This fish eats the different snails that we have found in the rivers from where our specimens were taken. The only exception is the large *Lanistes*, which is not known as a bilharzia host.

In ponds, the feeding habits of *Serranochromis* are slightly different. It eats more molluscs than it does in rivers: out of fifty fishes examined, 72 per cent have fed on snails, principally *Biomphalaria* and *Limnaea*.

A pond of about 0·1 acre, densely populated with *Physopsis* and *Biomphalaria*, was stocked with *S. macrocephala*. During the first month 87 per cent of the fish captured had eaten snails; after two months, this percentage had fallen to 44. A complete drying of the pond after three months did not reveal the existence of any small snails. The fact that some big *Physopsis* specimens survived was probably in relation with the small size of the fish (± 14 cm.). In a spawning pond with big breeders all snails had disappeared. Since this fish does not feed exclusively on snails, the complete disappearance of the latter does not harm his growth. Insect larvæ, crustaceans, other fishes, tadpoles, worms, etc., are eaten in different proportions.

In our ponds *Serranochromis* has already successfully spawned and we have many data about breeding habits, growth, resistance to manipulation, etc. We hope to have enough fingerlings before the end of the year to start distribution.

It may be added that this fish is a good sporting-fish and very palatable.

A few other species of fishes feeding on snails and mussels were studied at the same time. Among other siluroids we should like to mention *Chrysichtys mabusi* which, in its natural environment, feeds on molluscs. Curiously enough, even the thin shells of *Mutela* remain unbroken all through the digestive tract. *Chrysichtys mabusi* seems to be important for mollusc control in large permanent waters.

Change in the Composition of the Bottom Fauna of the Dogger Bank Area

F. M. Davis[1] has shown that, during the quantitative bottom investigations carried out with the Petersen grab over the Dogger Bank area of the North Sea during 1921–23, there was a pronounced dominance of the bivalves *Spisula subtruncata* (da Costa) and *Mactra corallina* (L.).

The Danish Commission for Fishery and Sea Investigations in May 1950 and 1951 undertook a similar investigation in the area with the research vessel *Dana*, comprising about two hundred samples taken with the 0·2 sq. m. van Veen and Petersen grabs. It was found that the above-mentioned species had decreased considerably in number as compared with the previous investigations. It also appeared that most other species recorded by Davis had increased in number.

Below, the finds made by Davis during voyage 48 (60 sq. m. of samples with the 0·2 sq. m. Petersen grab in October 1922), covering the central and western parts of the bank, are compared with the samples taken in May 1951 in the same area (11 sq. m. of samples with the 0·2 sq. m. van Veen and Petersen grabs). The difference in season of the year between the two investigations may be of some importance. However, during Davis's investigations the general aspect of the composition of the fauna did not change markedly with the seasons. The number per sq. m. of animals of different systematic groups is shown in the accompanying table.

	No. per sq. m	
	Davis (Oct. 1922)	*Dana* (May 1951)
Spisula subtruncata	272	5
Mactra corallina	11	1
Other species of bivalves	4	48
Polychaeta	4	70
Echinoderma	4	28
Other groups	8	65
Total	303	212
excl. *S. subtr.* and *M. cor.*	20	206

The total number of animals per sq. m. has d creased by one-third, though species other tha *Spisula subtruncata* and *Mactra corallina* have, o an average, increased their numbers about ten time This may be due to the presence of a greater amou of O-group animals of summer-spawning species i the autumn investigation than in the spring invest gation. (No marked difference in the efficiency of th two kinds of grabs was found.)

In 1951 the following five species were the mo numerous in the area (unbracketed: number per sq. n in 1951; bracketed: number per sq. m. in 1922):

Tellina fabula Gmelin	22	(0·5)
Ophelia limacina Rathke	14	(0·3)
Ophiura albida Forbes	11	(0·8)
Echinocardium cordatum Pennant	8	(1)
Eone nordmanni Malmgren	7	(0)
– (*Amphipoda* not yet determined).		

Eone nordmanni was not recorded by Davis, bu may have been confused with *Goniada maculat* Ørsted (Davis's voy. No. 48: 0·3; pres. inv. 2·9 pe sq. m.). However, some other species, which ar now present in fairly large quantities, were no found during Davis's voyage 48:

Echinocyamus pusillus (O. F. Muller)	6
Myriochele heeri Malmgren	5
Cerianthus lloydi Gosse	3

Since *S. subtruncata* and *M. corallina*, which hav decreased in number, represent a southern fauna element of the North Sea, the unusually cold winter of 1940–42 and especially 1947 may have influence their occurrence. However, the catastrophic effe of severe winters on stocks of marine animals wit a pelagic larval development will normally soon b counteracted by a heavy spat-fall of the same specie since the amount of larvæ produced by the reduce parental stock is sufficient for a quick renewal o the population[2]. In 1950 and 1951 the greater par of the specimens of *S. subtruncata* and *M. corallin* were obviously very old. This indicates a failure o spat-fall during the later years, showing an interferin of factors other than the effect of severe winters.

What brought about the changed composition o the fauna is still an unsolved question because w know very little of the stability of marine anima communities. In fact, it is not known whether th difference observed between the composition of th fauna during the two periods of investigation i indicative of a fairly constant change from one stat of balance to another, or whether it merely indicate the degree of fluctuation in the said area unde relatively stable conditions of environment.

It is intended to continue the investigations. Late a detailed report will be published elsewhere.

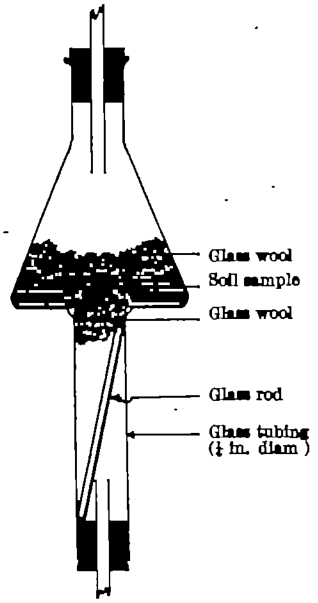
Modification of a Soil Percolation Apparatus for Soils of a High Organic Matter Content

DURING recent investigations of a number of soils e percolation method introduced by Schloesing and untz[1] was employed. The apparatus used was milar to that devised by Audus[2], as modified and scribed by Chase[3].

It was found that the reacting solution did not rcolate through soils of a high organic matter ntent after the first few minutes, even when sterile nd, or glass beads, or glass wool had been mixed ith the soil. It was apparent that a further modifican of the apparatus was required to obtain adequate rcolation with soils of this nature.



In order to permit the expansion of the soil during rcolation the straight glass column was replaced y the apparatus shown in the accompanying diaam. A hole was blown in the bottom of an Erleneyer flask of 125-ml. capacity. A short length of -in. diameter glass tubing was sealed to the opening us made. A pad of glass wool was inserted into is tube so as to protrude slightly into the flask; was held in position by a suitable length of glass d. The soil sample was placed in the flask and vered by a pad of glass wool to prevent excessive sturbance of the soil by the impact of the drops of e percolating fluid.

This alteration in the shape of the column used for ntaining the soil has permitted the investigation soils which could not previously be studied by is method.

One of the authors (T. M. B. P.) wishes to express s thanks to the National Research Council of anada for the award of a scholarship and permission publish this note.

Colour Change in the Echinoid, *Diadema antillarum*, Philippi

PHYSIOLOGICAL colour change has been but rarely reported in echinoderms[1]. Mortensen[2], in a footnote, makes cautious reference to the possibility of such changes occurring in *Diadema antillarum*; but it is clear that he was not aware of the striking manifestation of the phenomenon reported here, which occurs in young forms of this species. Indications of the existence of a rhythmic change in colour persisting under constant external conditions do not appear to have been reported previously in this form, nor indeed, so far as I am aware, in any other echinoderm.

By day, and in strong light, the young *Diadema* is almost uniformly black (Fig. 1). The spines (which have been cut short so as not to obscure the test) are banded with black and white; but their bases are always black.

By night, the sides of the test and the spine bases become pale grey, and in parts almost white, while aborally the test develops a strikingly brilliant white pattern in the form of a star around the periproct and enclosing the madreporite, extending into five interambulacral rays which bifurcate toward the ambitus (Fig. 3). Remarkable brilliant blue iridescent colours are to be seen at the edges of the white pattern.

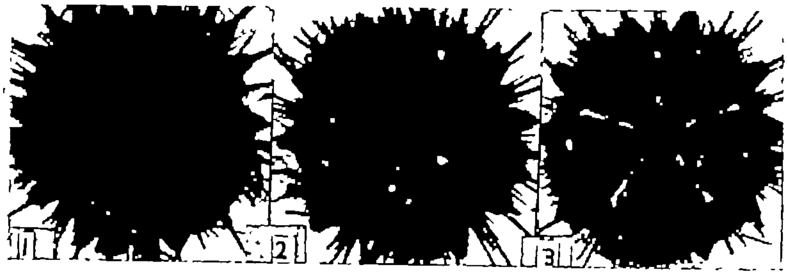
The change from the pale into the dark phase can readily be observed if the animal is placed under a 40-W. lamp, and requires 60–90 min. at 28° C. for the full range. A narrow beam of light projected on to the test brings about a localized development of the dark colour.

Examination under a low-power binocular shows that these changes are largely due to the dispersion and concentration of melanin in superficial chromatophores[1]. As the pigment disperses, there is not only an overall darkening, but also the white pattern becomes invaded by dispersing pigment, breaking up into isolated portions and eventually disappearing. During this time, the whiteness gives place to lilac and then brilliant blue, so that dispersion of light by melanin may also be involved in the play of colours that ensues.

The phenomenon is independent of the central nervous system or deeply situated nerve elements, since it occurs with equal readiness in small isolated pieces of test which have been scraped clean inside. It therefore appears to be due to the direct action of light on the chromatophores; but the possible existence of a localized superficial skin reflex, or the localized production and action of humoral agents, must be admitted.

Indications of a rhythmic colour change, independent of external lighting conditions, can be obtained by keeping an urchin in a light-proof tank. It will be found to darken distinctly during the day, and to assume characteristics intermediate between the pale and dark phases (Fig. 2). Further experiments are required, however, before it can be claimed that the temperature factor has been completely eliminated. Again, this change can be shown to be independent of the central nervous system.

As the young forms age, the colour changes become less striking and may largely disappear—a fact which may be related to the accumulation of melanin in these forms, for the change is still marked in albinotic or partially albinotic forms which are not uncommon in Jamaica. There is thus a morphological, as well as a physiological, colour change.



Photographs of young *Diadema* (diameter of test, 18·0 mm.). (1) Dark phase (photographed at 10.0 a.m. after being in sunlight); (2) intermediate phase (photographed at 10.0 a.m. after being in light-proof tank for 23 hr.); (3) pale phase (photographed at 8.0 p.m. after being in darkness for 3 hr.).

These photographs are of the same animal, using the same camera, illumination and plates. They were developed simultaneously in the same tank, printed on the same paper and given equal exposures both for photographing and printing

Since it has already been shown[4] that the whole surface of *Diadema* is remarkably sensitive to changes in light intensity, and moreover that the sensitivity increases markedly in the pale phase and declines in the dark, the dispersed superficial pigment in strong light may well serve as a protective shield for more deeply situated and widely scattered light-sensitive elements.

A full account of the investigation will be published in the near future.

The 'Capacitation' of the Mammalian Sperm

It was shown recently[1] that sperms injected into the periovarian sac of the rat after ovulation did not begin to enter the eggs until four or five hours later. In the rabbit, too, sperms introduced into the Fallopian tubes shortly *after* ovulation seldom penetrated the eggs; but if sperms were introduced a few hours *before* ovulation, the majority of the eggs were later observed to be fertilized. Chang[2] reported similar findings in the rabbit, and also showed that sperms, injected into the Fallopian tubes after ovulation, were able to penetrate a larger proportion of eggs if they had first spent about five hours in the uterus of another rabbit.

The conclusion drawn by both workers was that, in rats and rabbits, the sperm must undergo some form of physiological change or capacitation before it is capable of penetrating the egg. The need for such a change in the sperm has not been postulated before on direct evidence, and further confirmation is desirable. In the investigations already mentioned, the animals were necessarily subjected to laparotomy and the sperms to manipulation *in vitro*. Both these procedures may render somewhat abnormal the circumstances in which the penetration of the egg is to take place, and the following results are therefore of interest because they have been obtained with a minimum of experimental interference.

Mature female rats were selecte for œstrus by examining the vaginal smear between 6.0 and 7. a.m. and were placed in cages wit males for 10–15 min. between 7. and 7.30 a.m. That ovulation i normally complete at this tim was shown in a preliminary tes by the recovery of eight or mor eggs from the Fallopian tubes o sixteen out of twenty rats whic were killed between 5.0 and 7. a.m. The females which showe evidence of copulation wer selected, and individuals wer killed at 1, 2, 2½, 3, 4, 5 an 6 hr. later. The Fallopian tube were separated from the ute by severing the isthmus of the tube in order t avoid contamination with sperms from the uteru The distended portion of the ampulla was incise to permit the eggs in cumulus, together with th surrounding fluid, to escape on to a slide. The tub was discarded, and a coverslip with 'Vaseline' o the edges was placed over the preparation. The egg were inspected to see if sperm penetration ha occurred, and the number of sperms in the cumulu and surrounding fluid was counted. Results wer obtained from a total of seventy-five rats (see table)

Mean Number of Sperms Observed about the Eggs, and Tota Number of Eggs and Number of Penetrated Eggs Recovere from Rats Killed at the Specified Hours after Coitus

Hours after coitus	Number of rats used	Mean number of sperms about eggs	Total eggs	Penetrated eggs	Per cent penetrated eggs
1	10	6·6	74	0	0
2	15	20·6	139	1	0·7
2·5	10	33·5	96	21	21·9
3	10	32·1	88	39	44·3
4	10	49·9	94	65	69·1
5	10	55·4	91	78	85·7
6	10	59·6	82	80	97·6

The number of sperms found in the cumulus an surrounding fluid increased from a mean of 6·6 pe tube at 1 hr. after coitus to a mean of 59·6 per tub at 6 hr. In spite of the presence of sperms, none of th eggs examined at 1 hr., and only 1 out of 139 egg examined at 2 hr., were penetrated. At later hour increasingly larger numbers of sperms were see about the eggs and increasingly larger proportion of the eggs were found to contain sperms. At 6 h after coitus, eighty of the eighty-two eggs recovere (97·6 per cent) were penetrated.

Clearly, there is a delay of about two hours befor sperm penetration of the eggs commences, and thi is interpreted as support for the hypothesis that period for capacitation is required by the sper before it can penetrate the zona pellucida. There after sperm penetration proceeds readily.

I am grateful to Miss H. N. Turner for advice o the significance of results, and to my assistant, G. S Thring, for his careful work.

Rediscovery of the Ophiuroid Genus *Ctenamphiura* Verril

N September 10, 1874, H.M.S. *Challenger*, while lging at Station 188, at the western end of Torres ait, obtained from 28 fathoms two specimens of amphiurid which afterwards became the genotype he monotypic genus *Ctenamphiura*, receiving the e *Ctenamphiura maxima* (Lyman, 1879). It is arkable among amphiurids for its robust build, fact that the outer oral papillæ far exceed in the infradental pair, for its very large tentacle es, tumid disk and thick arms bristling with erect -spines arranged in dense comb-like masses. It never since been seen, nor has any related form n discovered so far as I can determine. Of the two specimens extant, one is in the British seum, the other in the Museum of Comparative logy, Harvard.

hrough the courtesy of Captain A. Black, Mr. H. Dawbin, of this Department, was able to dredge Pelorus Sound in December 1951, when he ained three specimens of an amphiurid, the ities of which were not at first obvious. It ered remarkably from any other known New land form. I now find that the Pelorus specimens ich were taken in 25–30 fathoms) conform in t respects with *Ctenamphiura maxima*, differing fly in the fact that the under surface of the is partly naked, and in the presence of only a le very large tentacle scale; also the massive -combs diminish in size on the proximal few es. There seems no doubt that the species must closely related to *C. maxima*, and, as the distinguishing features mentioned are diagnostic, it may e the name *Ctenamphiura dawbini* sp. nov. The e will be placed in the museum of this Department, a full description, with figures, will appear in the ology Publications from Victoria University lege". Fortunately, the species comes from an essible locality, from which, therefore, there is ry likelihood of further material being obtained he near future. It is hoped that at least a limited ount of material will soon be available for distribun to those museums which maintain important inoderm collections.

orrelation Study of Bovine Erythrocyte Antigen *A* and Butterfat Test

ERGUSON[1], in a discussion in a paper entitled eritable Antigens in Erythrocytes of Cattle", ed the possibility that certain of these cellular igens may be used as 'markers' in a study of the eritance of complex physiological characters such milk production. Filmer (personal communication) gested that the most logical antigen production tors to test would be antigen *A* and butterfat test, ause of the direct correlation between high freency of antigen *A* and of high butterfat test in sey, and low frequency of antigen *A* and low terfat test in Friesian cattle. Owen *et al.*[2] reported t 87·6 per cent of a group of Guernsey and 46·1 per t of a group of Holstein Friesian cattle carried igen *A*. Stormont (personal communication) mentioned that the frequency of antigen *A* in Jersey cattle is similar to that of Guernsey cattle. Results from New Zealand showed a frequency of antigen *A* in Jerseys and Friesians of an order similar to, but lower than, Owen's Guernsey and Friesian frequencies.

A survey on the lines suggested by Dr. Filmer was carried out in 1951. From nine herds of pedigree Friesian cattle, 95 blood samples were obtained from the 5 per cent of each herd with the highest butterfat test and the 5 per cent of each herd with the lowest butterfat test. Test records for the season 1949–50 were supplied by the New Zealand Dairy Board.

Results.

Highest 5 per cent of each herd had a butterfat test of 3·9 per cent or more.

Lowest 5 per cent of each herd had a butterfat test of 3·7 per cent or less.

Average test of all cows from which samples received, 3·84 per cent (range 2·8–5·0 per cent).

Number of animals with high butterfat test, 45. Frequency of antigen *A*, 0·27. Average butterfat test, 4·33 per cent (3·9–5·0 per cent).

Number of animals with low butterfat test, 50. Frequency of antigen *A*, 0·22. Average butterfat test, 3·36 per cent (2·8–3·7 per cent).

Overall frequency of antigen *A*, 0·24.

Cows with antigen *A*, 23 cows. Average butterfat test, 3·88 per cent (3·2–4·4 per cent).

Cows with high butterfat test, 4·23 per cent (3·9–4·4 per cent).

Cows with low butterfat test, 3·51 per cent (3·2–3·6 per cent).

Cows without antigen *A*, 72 cows. Average butterfat test, 3·82 per cent (2·8–5·0 per cent).

Cows with high butterfat test, 4·38 per cent (3·9–5·0 per cent).

Cows with low butterfat test, 3·34 per cent (2·8–3·7 per cent).

The test serum (Wallaceville anti-*A*) gives similar reactions to the Wisconsin *A*, kindly supplied by Dr. C. Stormont, but is less sensitive, that is, it does not react to quite so many bloods as does the Wisconsin *A*.

From the results, it appears there is no direct correlation between antigen *A* and butterfat test in the Friesian cattle under test. Even though the number of animals is small, it is likely that these results can be applied to Friesian cattle in general.

Toxicity of Methylene Blue to *Leptospira icterohæmorrhagiæ*

Yaniv and Avi-Dor[1] have reported that very low concentrations of methylene blue (0·5 µgm./ml.) inhibit the growth *in vitro* of *Bact. tularense*, but that this dye had no effect *in vivo*; "doses of 0·5 gm. [0·5 mgm. ?] each, applied intraperitoneally for three successive days, did not protect mice infected even with low doses (1–10 LD_{50}) of the bacterium".

So once again methylene blue has been found useless as a chemotherapeutic agent; and yet, in a sense, it may be regarded as the foundation stone of modern chemotherapy. As early as 1871 Ehrlich, the father of chemotherapy, had found that methylene blue preferentially stained malaria parasites, leaving the red blood cells and other tissues unstained; and in 1891 Guttmann and Ehrlich[2] reported that it had a slight anti-malarial action. Their finding was the starting point of the investigation that led to the discovery of 'Pamaquin', the first synthetic antimalarial. Later, Ehrlich and Hata[3] found that *in vitro* methylene blue was very toxic to the spirochætes of relapsing fever, but that *in vivo* it had no effect on the course of the disease in mice.

It seemed of interest to try the effect of methylene blue on a different genus of spirochætes, the leptospires, which have different growth requirements and a different distribution in the body. The test organism was *Leptospira icterohæmorrhagiæ*. *In vitro*, the organisms were immobilized and killed by very low concentrations of methylene blue (2 μgm./ml.); but *in vivo* doses of 10 μgm./gm. intraperitoneally on two successive days failed even to prolong the life of the test guinea pigs. The strain of *L. icterohæmorrhagiæ* used was highly virulent, and killed guinea pigs in four or five days. It is still possible that methylene blue might be effective in clearing the leptospires from the kidney tubules in cases of chronic infection; but this remains to be tested.

Phosphorus as a Factor Preventing DDT-Dehydrochlorination

DEHYDROCHLORINATION of DDT by certain chemicals concerns not only agriculture[1] but is also of great importance in anti-mosquito campaigns. A major factor here is the time during which DDT, sprayed on walls of houses, retains its insecticidal power. It has been shown[2] that great differences may exist between apparently identical walls, and that iron and aluminium ions are responsible for rapid dehydrochlorination. The difference in the percentage of mosquitoes killed on wooden and *pisé* walls, as reported by Wilkinson[3], might perhaps be explained on these lines.

In the Katanga Province of the Belgian Congo, I. Vincke also observed a rapid loss of insecticidal power of DDT on the walls of certain African houses. He asked us to investigate the problem. Using a modification of the method of Fleck and Haller, we also found that dehydrochlorination of DDT is related to the presence of iron and aluminium ions.

Analyses of soils from different parts of the Katanga have established the following facts: (1) in positive soils (causing rapid dehydrochlorination) there are ferric ions and few, if any, ferrous ions. Occasionally some slight traces of phosphate are found. (2) Negative soils contain both ferrous and ferric ions; the total iron content is generally higher than in positive soils. There is always a certain amount of phosphate.

Owing to a possible action of phosphate in neutralizing ferric ions by complex building, we have tried to use phosphorus to diminish the action of positive soils.

Laboratory experiments with water-soluble phosphorus salts, such as potassium hydrogen phosphates and ammonium phosphate, have given excellent results. Soils which dehydrochlorinized DDT completely after 12, 15, 17 and 20 min. respectively did not liberate any chlorine after 90 min. when p viously treated with a normal solution of such ph phates. Similar results were obtained with l positive soils which, before treatment, dehyd chlorinized 20 per cent of the DDT after 90 min

Tests on the coating of positive walls also show that a phosphate spray delayed the dehydrochlori tion of DDT for an appreciable time.

Using the biological tests of Downs *et al.*[2], we c conclude that in almost all cases the insectici power of DDT sprayed on walls may be prolon by previous spraying with a normal solution o phosphate.

This method has already been applied on a la scale by Vincke in the Tanganyika district of Congo.

Counting Soil Algæ by Direct Fluorescence Microscopy

THE dilution technique is not entirely satisfact in studying soil algæ. There is no universal medi for their growth, nor can we assume that all spec will grow on any artificial medium now in use. T slow growth of algal colonies involves delays of to two or three months, causing inconvenience routine work. Filamentous and colonial algæ int duce further difficulties. A single filament or colo can give one or many colonies according to t number of viable pieces formed from it during d persion. Available data on the number of algæ in t soil cannot therefore be regarded as absolutely certa

Only direct microscopy can resolve these di culties. Its use has been limited by the small numb of algæ present (sometimes only a few thousands p gram of soil). This involves counting many mic scopic fields, and the difficulties are increased by t small size of some algal cells and by their freque intimate association with soil particles. A n fluorescence technique is proposed to overcome th difficulties.

All active algal cells are believed to contain least one of the different chlorophylls. (We reser the question of resting stages which can lose th chlorophyll.) The red fluorescence of chlorophy illuminated with blue or ultra-violet light can be us for detecting and counting algal cells by the followi technique. The soil suspension is illuminat through a condenser (1·4 aperture), by a 12-volt 6-volt lamp, the light of which passes through solution of copper sulphate in aqueous ammonia. yellow filter below the eyepiece is used to abs blue light. Objectives of 10× or 20× are used wi a 5× eyepiece. Algæ appear as red spots or lin against a black background. Soil particles are usua invisible, but sometimes give a yellow or gre fluorescence readily distinguishable from that chlorophyll. Using a special slide with a depressi of 0·1 mm. deep, the amount of soil examined is function of the area of the field, and the number algæ per gram of soil can easily be calculated.

his rapid and direct technique requires neither ensive apparatus nor lengthy culture methods. It nts all soil algæ without selection.

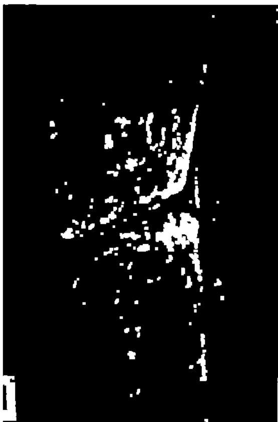
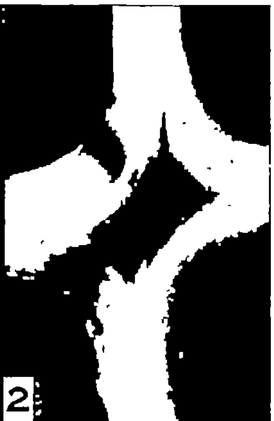
Formation of New Cell Walls in Cell Division

N a recent communication in *Nature*, further dence was presented by Dr. E. Elliot[1] relating the concept of Giltay[2], and supported afterwards Priestley and Scott[3], that at cell division each ighter protoplast secretes a continuous wall und itself. The suggestion was also made that s method of cell-wall formation may prove to be ieral in the higher plants. Recent work in this oratory on cell division in the cambium of angio- rms and gymnosperms further supports this ggestion.

Parts of an enveloping parent wall, apparently sisting after division in the ray initials, were served connecting adjacent cells of a radial file ray parenchyma cells isolated by simple maceration ig. 1). An example, which may perhaps be more portant, was observed in the course of a study of sequence of cell division of the cambium during the development of compression wood in conifer stems. Thin, feebly birefringent membranes, considered to be the remains of the parent cambial cell wall, were detected traversing the well-developed intercellular spaces characteristic of this tissue (Figs. 2 and 3). In normal wood the presence of similar membranes was demonstrated by careful delignification of thin cross-sections by alternate treatments with chlorine water and alcoholic monoethanolamine, with dilute alcoholic acetic acid washes (Fig. 4). Using techniques of simple maceration, demonstration of the parent wall was extremely difficult, as in the mature tissue this wall is not continuous around a radial file of cells and any slight agitation was sufficient to cause the cells to separate. That only fragments of the parent wall can be demonstrated is consistent with the great radial expansion of the cambium daughter cells which occurs during differentiation, following periclinal divisions.



ig. 1. *Grevillea robusta*. Part of two ray parenchyma cells, solated by maceration with hydrogen peroxide and acetic acid, howing part of parent wall of the ray initial. Unstained. × 980



ig. 2. *Pinus pinaster*. Transverse section of compression wood between crossed nicols. Only part of the parent wall traversing he intercellular space is in a position of brightness. × 2,000

ig. 3. *Pinus pinaster*. An example similar to Fig. 2, photographed with ordinary illumination after staining with safranin. × 980

ig. 4. *Pinus pinaster*. Transverse section of normal wood after delignification showing parts of the parent wall (marked by arrow). Unstained. × 430

A further point of interest is that the parent wall could not be demonstrated at the tips of cells by either of the techniques referred to above. This may be an indication of tip growth rather than of symplastic readjustment of the cells following cell division in the cambium.

Sugarcane × Bamboo Hybrids

Sugarcane × bamboo hybrids were first reported from this Institute by Venkatraman in 1937[1]. In spite of the absence of easily recognizable bamboo characters in the seedlings, Kutty Amma and Ekambaram[2] proved by a critical study of the anatomy and morphology of the seedlings that they were genuine hybrids. This corroborated Janaki Ammal's[3] conclusion arrived at earlier, on the basis of somatic chromosome counts. In these bamboo crosses the pistillate parents employed were the two male sterile Java canes, *POJ*.213 and *POJ*.2725. These were themselves complicated bispecies hybrids —*POJ*.213, involving *S. officinarum* and *S. barberi*; *POJ*.2725, a much more complicated hybrid between a number of *officinarum* and Java *spontaneum* (Glagah). It was felt desirable to repeat the cross, using a simple *officinarum* as the female parent. All the varieties of *officinarum* so far examined show $2n = 80$. For this purpose, *S. officinarum* var. *Vellai* (a local form) was employed and two seedlings were obtained. Examining the mother and the two seedlings derived therefrom through pollination with bamboo, one of the seedlings is very thick, much thicker than the mother, more vigorous and taller. The other is much thinner. Examination of the root-tips revealed a somatic chromosome number of 116 in the thick seedling and 86 in the thin. It is believed that the thick seedling has come into being through the fusion of an unreduced egg of *S. officinarum* (that is, $2n = 80$) with a normal sperm of *Bambusa arundanacea* ($n = 36$). The thin seedling has presumably been formed by the union of an *officinarum* egg having neither, the haploid nor the diploid number, with the sperm of bamboo. Functioning of diploid eggs in interspecific and intergeneric crosses, involving *Saccharum*, especially the species *officinarum* as one of the parents, is not an infrequent phenomenon. Almost all interspecific hybrids between *S. officinarum* × *S. spontaneum* have come into being through the operation of the unreduced egg of *officinarum*. Some cases of intergeneric hybrids are known where both the haploid and diploid eggs have functioned in the same cross. The latest known case is that of *S. officinarum* var. *Vellai* × *Narenga* ($2n = 30$), where hybrids showing $2n = 95$ and $2n = 55$ have been obtained (Raghavan unpublished). Functioning of egg with unexpected chromosome number in the formation of sugarcane hybrids is less common. While one such case is known involving a bicomplex hybrid as the pistillate parent, recent investigations have shown that this feature is shared by simple *officinarum* also. For *Co*.453, which is a cross between *S. officinarum* var. *Zw. cheribon* ($2n = 80$) and *Co*.285 ($2n = 112$), showed a chromosome number of 124, indicating that *Zw. cheribon* has contributed through its egg neither the haploid number (40) nor its unreduced number (80) but an unexpected number, that is, 68 [4]. This report is of interest in three particulars. First, instead of complicated bi-species or tri-species, derivatives such as *POJ*. or *Co*. canes, a simple *officinarum* has been employed as the pistil parent. Secondly, viable embryos are obtained from fertilization of not only haploid gametes, as reported by Janaki Ammal[3], but they are also formed from fertilization of unreduced eggs by normal sperms. This brings these bamboo hybrids into a line with *Saccharum* × *Sorghum* hybrids, in the formation of which also both reduced and unreduced eggs have been known to function[5]. Thirdly, the operation of an egg with unexpected chromosome number in the cross has also been vouched for.

Though the gross resemblance of the seedlings is to the mother, namely, sugarcane, the presence of such characters as arched root eyes above nodal buds of peculiar shape and disposition, extra-vaginal nature of the bud piercing the leaf-sheath, the mode of underground branching—these and other features, taken together with the chromosome number, leave very little doubt as to the genuineness of the cross. Perhaps this preponderance of maternal characters may be explicable on the basis of cytoplasmic inheritance, the existence of which was reported by Raghavan[4] in a number of interspecific hybrids in *Saccharum*.

A study of the intergeneric hybrids of *Saccharum*, which is now in progress, makes one believe that the seemingly conflicting phenotypic configurations obtained in several crosses are a result of the interaction of the plasmon with the genes. They seem to support the theory of the plasmon-sensitive genes in that it offers a reasonable foundation for the interaction of plasmon and genes; the result is that the same genes act differently in different plasmons. It would seem that in sugarcane hybridization more importance should be paid to the mother than to the father in the evolution of economically important seedlings. Also, the absence of fruitful results in the raising of economic seedlings through a particular cross need not be final; for it is just as likely that hybridization in the opposite direction, wherever such is possible, may result, through this interaction of the plasmon and the genes, in the expression of a phenotype answer to our needs.

Sex Mechanism in *Coccinia Indica* Wight and Arn.

SOME of the dioecious species of Cucurbitac have been cytologically investigated by seve previous workers to ascertain whether the morpl logical differences in flowers between the sexes cou be correlated with any observable chromoson differences of their gametes. So far, only t species among members of this family, name *Trichosanthes japonica*[1-3] and *Coccinia indica*[4-6] ha been found to possess well-defined sex-chromosom In *T. japonica*, the male is reported to be the heter gametic sex, whereas in *C. indica* contrary evidenc have been furnished by Kumar and Deodikar[6] a Bhaduri and Bose[4]. The present note is based the results of a critical cytological investigation different sex types, such as the diploid male a female, the gynodioecious form and a triploid ma of *C. indica*.

A careful examination of the somatic compleme in diploid male (Fig. 1,*a*) and female (Fig. 1,*b*) a of meiotic complement in pollen mother cells h definitely established that male of *C. indica* is t heterogametic sex with XY type of sex-chromosome Of this, Y is bigger than X while the latter is morph logically similar to the autosomes. During meios this unequal pair exhibits heteropycnosis, no congression, precocious segregation, etc., whic behaviours are characteristic of sex-chromosome The chromosome constitution of the male and t female of *C. indica* should, therefore, be represent as $22\,A + XY$ and $22\,A + XX$ respectively. T present investigation has definitely established th Kumar and Deodikar's statement[6] that the male *C. indica* is homomorphic and the female heter morphic is no longer tenable.

It has been observed that the chromosome co stitution of the gynodioecious form is similar to th of the normal diploid female ($22\,A + XX$) but, unli it, is highly sterile. In this the anthers are develope but pollen grain formation is impeded, resulting sterility of the plant. This provides an example show that the male organs of a plant can develo

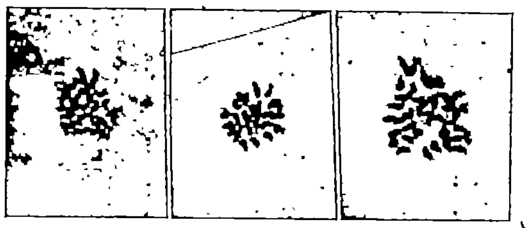

Fig. 1 (*a*), (*b*), (*c*). Somatic complement of diploid male and female a triploid male respectively. (× 1,100) n in the absence of *Y* chromosome. It further ows that there is something in the *Y* chromosome ich is necessary for the production of gametes but ich is absent in the *X* chromosomes and the tosomes.

A clone of a male plant conspicuous for its vigorous d extensive growth, when cytologically examined, s proved to be a triploid with 36 chromosomes (Fig.). Of these, one is large and very similar to the *Y* romosome observed in the diploid male, while all e rest are small and nearly alike. This *Y*, with uch two other chromosomes are associated during iosis, constitutes the *XXY* trivalent. The *Y* is arly distinguishable from the rest of the chromomes on account of its distinct size, shape and haviour. Thus from a knowledge of the chromome constitution in diploids and this triploid 3 *A* + *XXY*), it is quite evident that the influence *Y* is so overwhelming that the triploid, in spite the presence of two *X* chromosomes, has become perfect male plant. This lends further support to e suggestion made that the *Y* chromosome contains me element which is necessary for the formation gametes.

The occurrence of a triploid male reported here the first time shows that polyploidy exists within e species *C. indica*.

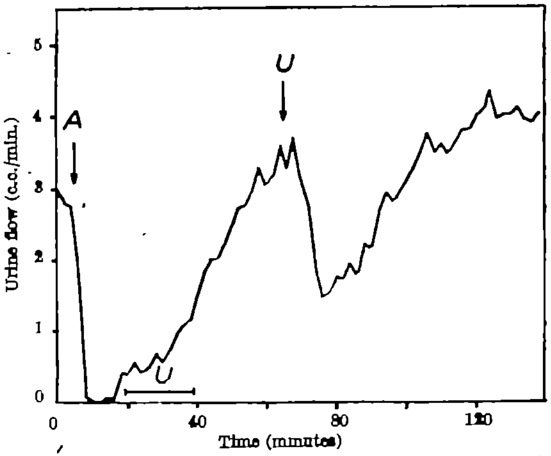
Adrenaline-Antidiuresis in the Water-loaded Dog

INTRAVENOUS injection of small doses of adrenaline s been observed to cause a temporary reduction the flow of urine in water-loaded dogs[1,2]. According Pickford and Watt[2], this action of adrenaline is pendent on alterations in renal blood pressure and w. We believe we have obtained evidence for the lease of the antidiuretic hormone by moderate ses of adrenaline.

After a fasting period of about 18 hr., in the course which water was given *ad lib.*, 30 c.c. of tap water r kgm. of body weight was introduced into the omach of a dog. A similar dose of water was given hr. later. Urine flowing through the inserted theter was collected in graduated tubes and easured every 2 min. After the beginning of steady w, doses of adrenaline varying from 0·008 mgm. 1 mgm. were administered intravenously. The gs were unanaesthetized during the experiments.

Adrenaline in doses of about 0·01 mgm. induced typical short adrenaline-antidiuresis as earlier scribed by Verney[1]. Injection of doses of 0·04–0·2 gm. was followed by a biphasic antidiuresis. First, rapid transitory inhibition of the flow of urine of e adrenaline-type appeared. Thereafter, a more olonged inhibition, resembling that caused by the tidiuretic hormone[1], began and reached the maxium at about 20 min. from the time of the injection.



Water-diuresis curve from the bitch 'Diogenes', in a Pavlov stand. At *A*↓, 0·5 mgm. adrenaline was injected intravenously. Urine was collected at *U*—, and re-injected at *U*↓

If 0·5 mgm. or more of adrenaline was injected, the antidiuresis was either mono- or bi-phasic. In the monophasic reaction, as is seen from the accompanying graph, the rate of flow of urine rapidly decreased to zero, increased gradually, and reached the pre-injection level in about 40–60 min.

The mechanism of this antidiuretic effect of adrenaline is not yet clear. However, the form of the curves suggests the possibility that moderate doses of adrenaline may cause, besides a rapid inhibition of flow of urine typical of this substance, a release of the antidiuretic hormone from the posterior pituitary. To investigate this possibility, urine collected during the period of adrenaline-antidiuresis was intravenously injected into the same dog. This urine was observed to have a pronounced antidiuretic action, as demonstrated in the graph. Control samples collected during uninfluenced diuresis for similar periods did not produce any comparable inhibition of flow of urine. An inhibition of the observed magnitude can be obtained with a dose of 0·1–0·2 mgm. of adrenaline. However, the excretion of some 20–40 per cent of the total amount of adrenaline injected in the course of 20 min. appears unlikely. Adrenaline alone is therefore scarcely likely to be responsible for this antidiuresis. On the other hand, the antidiuretic hormone is in part quickly excreted and can be detected in small amounts of urine, as observed by O'Connor[3], whose technique was adopted in this study. Hence the effect of the urine excreted during the adrenaline-antidiuresis supports the view that the prolonged stage of this antidiuresis is due to the release of the antidiuretic hormone. Direct evidence is, nevertheless, still lacking. In view of the fact that small doses of adrenaline inhibit the release of the antidiuretic hormone as induced by various stimuli[1], the eventual converse effect of larger doses is of special interest.

More detailed description of the results will be published elsewhere.

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

ASSISTANT IN STATISTICS—The Secretary, The University, Aberdeen (August 30).

ASSISTANT LECTURER IN MATHEMATICS—The Registrar, University College, Leicester (August 30).

CHEMIST (Experimental Officer grade) in the Fungicide and Insecticide Research Co-ordination Service in London—The Secretary, Agricultural Research Council, 15 Regent Street, London, S.W.1 (August 30).

SENIOR ASSISTANT ENGINEER (Chemist) (with an honours degree in chemistry, or a degree with chemistry as a principal subject) for work on the technical aspects of pollution of water-ways of all kinds and the treatment of natural waters for the prevention of slimes and deposits in heat-exchangers—The Director of Establishments, British Electricity Authority, British Electricity House, Great Portland Street, London, W.1, quoting AE/274 (August 30).

ASSISTANT BIOCHEMIST to work at the Group Laboratory, Warwick Hospital, and at the King Edward VII Memorial Sanatorium—The Pathologist, Group Pathological Laboratory, Lakin Road, Warwick (August 31).

ASSISTANT EXPERIMENTAL OFFICER (with a degree in horticulture and an interest in horticultural research, especially regarding the preparation and handling of horticultural produce for marketing) to investigate the effects of washing of vegetable produce—The Secretary, National Vegetable Research Station, Wellesbourne, Warwick (September 1).

ASSISTANT LECTURER IN PHYSICAL CHEMISTRY—The Secretary, University College, Earlsfort Terrace, Dublin (September 1).

ASSISTANT LECTURER IN MATHEMATICS (with special qualifications in pure mathematics)—The Registrar, The University, Manchester 13 (September 6).

ASSISTANT LECTURERS (2, one of whom at least should have qualifications in general mycology or microbiology) IN THE DEPARTMENT OF BOTANY—The Secretary, University College, Gower Street, London, W.C.1 (September 6).

LECTURER IN ELECTRICAL ENGINEERING—The Assistant Secretary of University Court, The University, Glasgow (September 6).

SCIENTIST III or SCIENTIFIC TECHNOLOGIST I (with a science degree or equivalent qualification) for the assembly, recording and reporting of scientific data on coal seams, at the Coal Survey Laboratory at Birmingham—The National Coal Board, Establishments (Personnel), Hobart House, Grosvenor Place, London, S.W.1, quoting TT/518 (September 6).

SENIOR LECTURER or LECTURER IN CROP PRODUCTION, in the Department of Agriculture, University College of the Gold Coast—The Secretary, Inter-University Council for Higher Education in the Colonies, 1 Gordon Square, London, W.C.1 (September 6).

LECTURER IN BOTANY (qualifications in plant physiology essential)—The Secretary, The University, Aberdeen (September 8).

LECTURER IN PARASITOLOGY in the Department of Zoology—The Secretary, The University, Edinburgh (September 8)

ASSISTANT (with interests on the physical and inorganic side) IN THE DEPARTMENT OF CHEMISTRY—The Secretary, The University, Aberdeen (September 10)

LECTURER (with an honours degree in physics, with research experience, and interested in the design of optical, electronic and pressure-recording apparatus) IN BIOPHYSICS—The Secretary, The University, Edinburgh (September 10)

DISTRICT (Forest) OFFICERS—The Secretary, Civil Service Commission, 6 Burlington Gardens, London, W.1, quoting No. 146/52 (September 11)

LECTURER (Grade I or II) IN PHARMACEUTICAL CHEMISTRY, and a LECTURER (Grade II) IN AUTOMOBILE ENGINEERING AND VEHICLE TECHNOLOGY, at the Kumasi College of Technology, Gold Coast—The Secretary, Advisory Committee on Colonial Colleges, 15 Victoria Street, London, S.W.1 (September 12).

ASSISTANT KEEPER (Geology)—The Director, Museums and Art Gallery, Leicester (September 15).

ASSISTANT LECTURER IN CHEMICAL ENGINEERING, an ASSISTANT LECTURER IN FUEL TECHNOLOGY, and an ASSISTANT LECTURER IN GAS ENGINEERING—The Registrar, The University, Leeds 2 (September 17).

PRINCIPAL SCIENTIFIC OFFICER at the Mechanical Engineering Research Laboratory, East Kilbride, Glasgow, to lead a team engaged on the thermodynamic tables programme of the Heat Division—The Civil Service Commission, Scientific Branch, Trinidad House, Old Burlington Street, London, W.1, quoting No. S 4161/52 (September 18).

RESEARCH STUDENTSHIP IN MATHEMATICS, and an ASSISTANT LECTURER IN MATHEMATICS—The Professor of Mathematics, University College of North Staffordshire, Keele, Staffs (September 20).

ASSISTANT AGRICULTURAL ECONOMIST (graduate in economics and/or agriculture)—The Registrar, The University, Bristol (September 30).

SENIOR LECTURER and a LECTURER IN ANATOMY, and a SENIOR LECTURER IN BACTERIOLOGY, at University College, Ibadan, Nigeria—The Secretary, Inter-University Council for Higher Education in the Colonies, 1 Gordon Square, London, W.C.1 (September 30).

SENIOR RESEARCH SCIENTIST (with a wide knowledge of physical chemistry and/or biochemistry) for a research post which will also involve a considerable degree of supervision of the work in progress in the Association's laboratories—The Director of Research, Baking Industries Research Station, Chorleywood, Herts (September 30).

LECTURER (Grade II) IN INDUSTRIAL METALLURGY—The Registrar, The University, Birmingham 15 (October 1)

SENIOR LECTURER IN GENERAL CHEMISTRY at the University of Melbourne—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (October 31).

DEPUTY EXECUTIVE OFFICER (with a recognized degree in agriculture or natural science) OF THE SEED PRODUCTION BRANCH, a REGIONAL TRIALS OFFICER (with a University degree or diploma in agriculture and/or biology) (to be stationed at the Harper Adams Agricultural College, Newport, Shropshire), and an ASSISTANT (with a recognized degree in agriculture or natural science) to the Mycologist—T Secretary, National Institute of Agricultural Botany, Huntin Road, Cambridge.

EDUCATIONAL PSYCHOLOGIST (part-time) (honours graduate psychology)—The Medical Director, Child Guidance Training Cen 6 Osnaburgh Street, London, N.W.1.

ELECTRICAL ENGINEERS (Senior Scientific Officer grade) for w connected with the design and development of remote power c trolled gear and servo mechanisms, at a Ministry of Supply De Establishment near Sevenoaks—The Ministry of Labour and Natio Service, Technical and Scientific Register (K), Almack House, 26 K Street, London, S.W.1, quoting D.329/52A.

EXPERIMENTAL OFFICER IN THE RADIO RESEARCH ORGANIZAT at Toddington, for abstracting scientific and technical articles radio research and development—The Ministry of Labour and Natio Service, Technical and Scientific Register (K), Almack House, 26 K Street, London, S.W.1, quoting D 268/52A

LECTURER IN MECHANICAL ENGINEERING (including heat eng and hydraulics)—The Principal, Faraday House College, Sou ampton Row, London, W.C.1.

MATHEMATICIAN or PHYSICIST (Principal Scientific Officer gra at a Ministry of Supply Design Establishment near Sevenoaks, lead a section dealing with mathematical/physical investigatio including theoretical aspects of design problems—The Ministry Labour and National Service, Technical and Scientific Register (Almack House, 26 King Street, London, S.W.1, quoting A.220/52

MECHANICAL ENGINEERS for research work connected with t preparation of airframe Appendices A at Ministry of Supply Lond headquarters—The Ministry of Labour and National Service, Techni and Scientific Register (K), Almack House, 26 King Street, Lond S.W.1, quoting C.493/52A.

RESEARCH ENGINEER (with B.Sc. or equivalent, and some engineer workshop and drawing office experience essential) for design and testi of experimental equipment—The Assistant Secretary, British C Utilization Research Association (Ref. No. A 19), Randalls Roa Leatherhead, Surrey.

SENIOR SCIENTIFIC OFFICER (Veterinary Research) at the Cent Trypanosomiasis Institute, Sukulu, Uganda, to undertake resear in animal trypanosomiasis—The Director of Recruitment (Colon Service), Colonial Office, Sanctuary Buildings, Great Smith Stre London, S.W.1, quoting Ref 27066/84/52.

NATIONAL PARKS AND LOCAL GOVERNMENT

IN the House of Commons debate on national parks and access to the countryside, held on July 14, Mr. Harold Macmillan, the Minister of Housing and Local Government, announced his agreement to the administration of the Snowdonia National Park for its first three critical years by three county committees with a joint advisory committee instead of the statutory joint board with its planning powers. The agreement was subject to six conditions, which included a fixed office and an independent planning officer; and, with the acceptance of these conditions by the three county councils concerned, only an appeal to the courts can now prevent this dubious decision taking effect. Mr. Macmillan in the debate made no attempt to justify his departure from the terms of the Act. His concession to local feeling does indeed appear to rest on a desire to secure an effective national park and on the recognition that the co-operation of the local authorities is essential if the national parks are to succeed, a recognition, however, which is fully shared by those who, like Mr. Anthony Greenwood and Mr. Blenkinsop, opposed his action.

Nobody, however, proposes, as Mr. Macmillan and Mr. Ernest Marples implied, to ride roughshod over the local interests. What the Minister and his Parliamentary Secretary seem to have overlooked is that it was largely the failure of local planning authorities to pay enough attention to the national interests that made the Act necessary. Opposition of the type displayed by the Merioneth, Caernarvonshire and Denbighshire County Councils was visualized as likely to lead to control of the national parks being taken completely out of the hands of the local authorities.

Moreover, while there is no reason to doubt the genuine desire of the three county councils concerned to establish a national park in Snowdonia, Mr. G. O. Roberts's speech in the debate shows why it is unwise, if indeed it is fair, to entrust policy or administration to local authorities. Where there is a clash between national and local interests, the local authorities are subject to an unfair tension; their financial resources are unequal to the task, and the major threats to national parks come from government departments and the large public authorities with which the local authorities are manifestly unable to contend on equal terms.

These are the critical issues, and they have been consistently passed over by the present Minister of Housing and Local Government and his Parliamentary Secretary as they were, on the Labour side, by Mr. Dalton and Mr. Blenkinsop. Moreover, in his speech on July 14 Mr. Macmillan advanced no satisfactory justification for ignoring the intention of the Act in this replacement of the joint planning board by a joint advisory committee.

Something much more fundamental than mere expediency is here at stake. It is already clear from the course of events since the National Parks Act was passed in 1949 that the populations—and certainly the local authorities—of the districts chosen for the establishment of the national parks are indifferent, if not hostile, to the needs and desires of their urban neighbours and still more to the national considerations which led to the passing of the Act by Parliament. Both populations and local authorities have also shown a remarkable ignorance of the whole conception of a national park in Britain, and, to say the least, neither of the Ministers concerned have seemed prepared to give the National Parks Commission the resources to enable it to dispel ignorance which sometimes appears almost wilful. For evidence of this one need look no further than to the second report of the National Parks Commission or to some of the statements made before the public inquiry on the Minister's Order designating the North Yorkshire National Park. At that inquiry the Minister was urged both to delay confirmation of the Order for three years and to reduce the area from the 600,000 acres designated by the National Parks Commission to 250,000 acres.

Once again the representative of the National Parks Commission had to reiterate that designation of a national park did nothing to increase public access to farmland, and he pointed out further that the opposition of the Whitby, Thirsk and Hull water undertakings, the Blackfaced Sheep Breeders' Association and the Country Landowners' Association to the designation order was based on misapprehensions and misconceptions of the effects of designation which had been refuted at previous national park inquiries.

If opposition is frequently due to misconceptions and misunderstandings, it can be changed into co-operation when there is proper appreciation of the purpose and functions of a national park and the difference between it and ordinary county planning. That much is clear from the work of the Peak District National Park Planning Board. The few months experience of that body has convinced some of its members who were most opposed to a joint board, and anxious for an advisory committee instead, that a joint board can work effectively. The members of the Board have already shown their impartial outlook in considering industry and amenities, and are evidently growing out of a parochial idea of their responsibilities into one that is inspired by the conception of a national park which induced Parliament to pass the legislation.

Here there is evidence that a joint board can function and that its members recognize that success depends on the ability of its members to carry with them the authorities which they represent. Confidence that the joint advisory committee which Mr. Macmillan proposes for the Snowdonia National Park will, in fact, be guided, as he desires, by the National Parks Commission, will not be strengthened by the recent decision of the Dartmoor National Park Committee to sanction the erection of a television mast on North Hessary Tor. Both the Dartmoor Preservation Association and the National Parks Commission have asked the Committee to reconsider its decision, but without effect. In spite of this, neither Mr. Macmillan nor Mr. Marples in the debate on July 14 brought forward any evide to justify their optimism over the surrender national control.

It is clear enough, therefore, that if the co-operati and understanding of the local authorities, on whi Mr. Marples, like his opponents, rightly lays su stress, is to be secured and, still more, if the financ support which he referred to as "quite indispensab in addressing the annual meeting of the Sheffi and Peak District Branch of the Council for t Preservation of Rural England is to be obtain a vigorous educational campaign must be und taken as a matter of urgency. The gravest dou as to the good faith of the Labour Party in th matter were roused by the actions of Mr. Dalton a Mr. Blenkinsop, and in using the adjournment deba on July 9 and the debate on July 14 to attack t Government on party lines. But Mr. Macmillan a Mr. Marples have need enough to establish their ov sincerity and good faith, and it is to be hoped th in its next annual report the National Parks Com mission will no longer have to complain that it unable to conduct essential publicity campaigns f lack of the relatively small sum of £300.

The Minister will doubtless discount or ignore an attacks upon his policy made on party lines. I can scarcely overlook the fact, however, th members of his own party, and that doubts to his intentions have been raised by his ov actions in the minds of many responsible an independent people throughout the country. The doubts were not dispelled by his speech on July 1 and if any progress is to be made with the establis ment of real national parks, some proof, rather tha words, must be forthcoming to show that t Government is really concerned with the claims amenity, of which Mr. Marples spoke so disparagingl It should be noted, for example, that in its annu report this year the Council for the Preservation Rural England reached the conclusion, from a revie of various disputes with the authorities over ele tricity undertakings, and particularly the Malve Hills case, that the tendency among governme departments and local authorities to pay scant rega to the claims of amenity is increasing. Sir Patri Abercrombie, too, has contended that despite co sultation, public inquiries and departmental inquirie these large impersonal organizations have become f all practical purposes above the law and outside t control of planning authorities.

That contention is completely endorsed by t Council for the Preservation of Rural England ar is, as already indicated, one of the fundament reasons for the concern with which Mr. Macmillan departure from the administrative proposals of t National Parks Act is regarded. Instead of harpi on the need for securing the co-operation and unde standing of the local authorities, on the importan of which all are agreed, the Minister should first ta positive action to assist the removal of misconceptio and misapprehensions, to the persistence of which t North Yorkshire Moors inquiry bore witness, an second, inquire himself a little more closely into t reasons for such misapprehensions.

Two such causes have already been indicated : st, the slender resources which the National Parks mmission has at its disposal for publicity ; and ond, there is this question of control of depart- mtal requirements—land needs of the Armed rvices, mineral workings, water supply, electricity dertakings and others. Some independent means assessing such requirements in relation to national eds as a whole is imperative. If we continue to ow departments to be judges in their own cause, ither nature reserves nor parks, national or local, r even cricket fields are likely to survive in Great itain.

But there is a third cause at which Mr. B. Keith- icas hinted in his recent book, "The English Local vernment Franchise" (Blackwell, 27*s*. 6*d*.). The pute over the administration of the national parks a facet of the general problem of the relations be- een central and local government. For many years e powers and responsibilities, obligations and re- urces of local authorities have been getting out of gnment. To a large extent local authorities spend ney which is not their own on policies which are not their making. More and more local expenditure is ed by forces outside the control of the individual thority, and this fixed expenditure tends steadily increase, with consequent limitation of the area of itiative for the local authority. For example, half e gross expenditure of a large county borough may on salaries and wages, in accordance with scales ed by some independent body or by a national nt council.

While the local authority remains free, within nits, to reduce or increase its staff, it has largely st the power to fix conditions of service, except in far as it acts through some national negotiating dy ; in such circumstances it is understandable at local authorities should look askance at any oposals which would extend further the power of tional standards to enforce a certain minimum penditure on the local authorities. Mr. Keith- icas points out that extension of the system of joint ards proposed for the administration of national rks might well constitute a major threat to the dependence of local government in Britain. Whether e system does, in fact, mark the beginning of a new rm of central control of locally elected bodies cannot t be seen. It is not clear, for example, whether the vernment nominees on such committees are free ents or whether they are expected to represent the as of the Government ; but in the context of the neral tendency for central control to go beyond at is justifiable either by present economic diffi- lties or by the financial aid given, the misgivings some of the local authorities in this matter are derstandable even if they cannot be condoned.

From this point of view it is equally clear that the ime responsibility for removing misunderstanding d opposition lies on the Government's shoulders. vernment parsimony has not only impeded the moval of misapprehensions as to the nature of tional parks, but has also accentuated the justi- ble fears of the local authorities as to the effect on eir financial resources. If there is to be a national policy, it must be implemented from national resources : the execution of such a policy should not depend on the ability of a particular local authority to supply the resources. If that were made clear, there would be less question of the willingness of local authorities to co-operate in working out a national policy which took full account of local interests as well as of the wider and long-term national and special interests, with which it is unreasonable to expect local authorities primarily to be concerned.

The abandonment of the Hobhouse principle that national parks should be nationally financed and administered was a mistake for which both political parties share the responsibility. The experience of the Peak District National Park Board, as already indicated, warrants the hope that collective exercise by such a Board of executive control over the whole of a park area may induce in its locally elected members a sense of independent and united purpose, of loyalty to the conception of a national park and of responsibility to the nation as a whole as well as to their own ratepayers. It is even possible to see here one of those fields for enterprise which are so important if local government is to retain vitality, and it should be noted that in a useful report on the scope for enterprise in local government, put out last year by the Research Panel of the National Association of Local Government Officers, some stress was laid on the importance of evolving new patterns of co-operation.

That report gave due weight to all those factors which we have suggested as helping to explain the attitude of local authorities to the national parks In spite of these difficulties, however, and the limitation of experiment which central control and the economic situation place on even the counties and county boroughs, the report took an optimistic view of the scope for enterprise in local government. Particularly in the social services and in amenities, a vast sphere of work is still open to local authorities both in the technical development of services and in the development of systems of co-operation and administration.

National parks or nature reserves were not mentioned in this report ; but the bearing of the conclusions of this report on the national parks question is unmistakable. If, however, local authorities are to respond to the challenge which is offered to them, a large measure of responsibility lies on the shoulders of the Minister of Housing and Local Government : he must no longer allow the educational activities of the National Parks Commission to be hamstrung for paltry sums ; he should dispel such misgivings on the part of the local authorities as are directly due to the Ministry's refusal to provide the planning authorities of particular parks with the financial resources required for effective national planning ; and he should terminate an appeasement policy which threatens to jettison the declared intentions of the Act in the face of misinformed opposition based on misconceptions for which the Ministry's policy is in part responsible.

Action in these matters will provide the best test of the Minister's belief in the idea of national parks and his desire for the efficient administration which he has admitted is to be secured by a single authority such as a joint board. Mr. Macmillan has, moreover, indicated his acceptance of the principle that, in the areas designated as national parks, amenity is to be regarded as the overriding national interest; though the whole trend of his speech suggested that at the present time he attached rather a low importance to amenity as compared with other national interests. The danger is, of course, that irreparable damage may be done to amenity in the meantime if in some areas that interest is not supreme even at the present time.

For all that, there is evidence in Mr. Macmillan's speech of his ability to see the problem as a whole and to put the question of national parks in its proper perspective. It is his actions that have aroused doubts as to his intentions; but fortunately there is other and more reassuring evidence of his energy and initiative, such as his direction requiring all fresh applications for granting permission to extend or open quarries in the Peak District to be made to the Peak District National Park Planning Board in the first instance, and more particularly in that larger question of local government to which the question of national park administration is related. How close is that relation, and how large an opportunity for the invigoration of local government the wise administration of national parks by such devices as a joint board offers, are well brought out in a recently published study by Mr. D. N. Chester of the financial and administrative relations between central and local government. Two chapters, in particular, of this book—that in which Mr. Chester sets forth the assumptions on which his study is based and that in which his criticisms and proposals for improving such relations are detailed—deserve attention as much from the point of view of the administration of national parks as of the reform and reinvigoration of local government. They could well contribute to effect the closer co-operation and understanding, on the necessity of which in an effective national parks system all are agreed.

HISTORY OF BOTANICAL EXPLORATION IN MALAYSIA

Flora Malesiana

Being an Illustrated Systematic Account of the Malaysian Flora, including Keys for Determination, Diagnostic Descriptions, References to the Literature, Synonymy and Distribution, and Notes on the Ecology of its Wild and Commonly Cultivated Plants. (Published under the auspices of the Botanic Gardens of Indonesia, Bogor, and of the Rijksherbarium, Leyden.) General Editor: Dr. C. G. G. J. van Steenis. Series 1: Spermatophyta, Vol. 1: Malaysian Plant Collectors and Collections; being a Cyclopædia of Botanical Exploration in Malaysia, and a Guide to the Concerned Literature up to the Year 1950. By Mrs. M. J. van Steenis-Kruseman. Pp. clii+639. (Djakarta and Groningen: Noordhoff-Kolff N.V., 1950.) 55.50 fl.

THE "Flora Malesiana" now in progress of publication is a magnificent effort designed to give a detailed and systematic account of the botany and vegetation of 'Malaysia', including the Mala
Peninsula, Indonesia, the Philippine Islands, Briti
Borneo, Portuguese Timor and New Guinea. It wi
we are told, be preceded by three volumes of
general character, of which the present one is th
first to be published. This volume has been writte
by Mrs. M. J. van Steenis-Kruseman and has as
separate title, "Malaysian Plant Collectors an
Collections; being a Cyclopædia of Botanic
Exploration in Malaysia, and a Guide to the Co
cerned Literature up to the Year 1950". It is eviden
that much bibliographical and biographical researc
spread over a period of approximately twelve yea
and involving the immense task of consulting
world-wide literature on the subject, has gone in
the preparation of this volume. The result has bee
the building-up of a fully comprehensive an
informative work, the most complete contribution
our knowledge of the history of botanical exploratio
in Malaysia ever published.

The introduction to the volume, forming Chapter
covers more than thirty pages and outlines the ai
and history of the work and its purpose as part
the "Flora Malesiana". It goes on to deal wit
private collections of Malaysian plants, gives copiou
notes on mislabelled botanical collections, and includ
an annotated list of the literature for the use
explorers, ending with an account of the etymolog
of vernacular names for the plants. All those wh
intend to collect in the tropics will find the direction
contained in the chapter on the technique of plan
collecting invaluable. The dangers encountered, th
equipment needed, what and how to collect, th
dispatch of living plants, and many other matte
are described in a full and detailed manner. Indee
the information will doubtless be found useful
many people other than botanists, and the wide fiel
covered by the volume should result in a demand fo
it by those with interests in the history of oth
branches of science such as zoology, etymolog
agriculture, horticulture, medicine, forestry, ethno
graphy, geography and so on.

In Chapter 3 the delimitation of Malaysia and i
main geographical divisions are dealt with an
include unpublished data, while diagrams and figur
are given to illustrate distribution. Attention is pa
to the inner divisions of the flora, and the theori
and arguments of Earle, Sal. Müller, Zollinge
Miquel, Wallace, Merrill, Malm and Dickerson a
discussed. Reference to the collections is made in th
next chapter, which gives a complete list of th
voyages and expeditions in chronological order an
also provides a useful geographical survey. Desiderat
for future exploration are next considered, an
attention is given to the work of future botanic
collecting. Another chapter contains references
important sources of information used in compilin
the list of collectors and also includes other inform
tion relating to herbaria where collections of Malaysia
plants are to be found. There are also sevent
specimens of facsimile handwriting of well-know
botanists, which will no doubt be found extremely us
ful in identifying handwriting on herbarium sheets.

The rest of the volume, consisting of 639 pages,
devoted to a very valuable cyclopædia of collector
This contains brief biographical sketches of som
three thousand people who have been concerned
some time or other with the botany of Malaysi
Itineraries, collecting localities, collections an
literature follow the sketches, and many portraits a
included. Here many celebrated men are dealt wit

as Solander, Banks, Thunberg, Commerson, k, Korthals, Koorders and so on. In many cases, biographies have hitherto been available or were to be found in special or obscure publications. book ends with a select index which has evidently n carefully compiled.

ne can have nothing but praise for this book, ch is a veritable mine of information. To all anists interested in or visiting Malaysia it will be te indispensable. H. S. MARSHALL

e Control of Public Expenditure
ancial Committees of the House of Commons. By il Chubb. Pp. viii+292. (Oxford: Clarendon es; London: Oxford University Press, 1952.) . net.

R. BASIL CHUBB'S scholarly survey of the financial committees of the House of Commons concerned not, as the original Public Accounts nmittee, with unauthorized spending, but with e spending—the most efficient use of public ney. Nor are controls of the type which are here isidered a substitute for efficient administration. at is the first and indispensable safeguard, and system of control which Dr. Chubb reviews in s book might be described essentially as one of aining *prima facie* evidence that administration is fact sound. This study shows what care has been en to avoid infringing departmental responsibility l to secure the co-operation of the departments in viding the information essential for the formation a balanced opinion upon their activities.

uch co-operation and the provision of adequate ormation are the essential conditions for inde- dent control of this type. There are others which . Chubb also puts forward as necessary if a Select mmittee is to examine expenditure effectively: ticable and clear-cut terms of reference; an propriate organization; means of ensuring that tice is taken of its recommendations; and liaison d co-ordination arrangements with the Public counts Committee. Given these, and there is no son why the essentially amateur character of such Select Committee's inquiries, in contrast to the re professional probing of accounts by the Public counts Committee, with the expert assistance and idance of the Comptroller and Auditor General and Audit Department, should not yield extremely ful results. Even such a complicated and technical estion as the national organization for scientific d industrial research has been usefully probed in s way, as the third report of the Estimates Com- ttee for the session 1946–47 shows.

The work of the Estimates Committee and of the blic Accounts Committee appears, in fact, already have shown the lines along which control is to be ected. The task confronting us to-day is to termine exactly what new type of information is quired regarding such bodies as the University ants Committee and the Department of Scientific d Industrial Research for an accurate appreciation the efficient performance of their services and the dom of their expenditure. With this there may o be required, indeed, something more than a ancial scrutiny—a scrutiny of method, based on the investigation of departmental practice and organization. Largely this will be a matter of departmental administration, though in part it may be stimulated by the inquiries and activities of the Select Committee.

How far any really radical change in this respect is necessary cannot easily be judged from Dr. Chubb's review. Seldom, if at all, does he indicate the outcome of the recommendations of the Select Committee on Estimates, and we are given no means of judging whether or not there exist at present adequate means of ensuring that notice is taken of the recommendations of the Estimates Committee. This, however, is vital if the work of the Committee is not to be in vain, and public control is to be a reality and not a sham.

Dr. Chubb's book gives a clear historical account of the development of a system that has already served us well. His book is also to be welcomed as a pointer to the directions in which fresh thought and study are required if we are to adapt the system to serve still more closely the conditions of to-day, and particularly to solve such problems as those of the control or investigation of the great public corporations and of the formation of an educated public opinion which is not only satisfied that money is wisely spent, but also understands the relation of such expenditures to national welfare clearly enough to be immune from hysteria at a time of economy. Such problems involve scientific study by some at least of the Departments of State: they equally involve co-operation and hard thinking among scientific workers and technologists, as well as administrators, by whom and on whom some of these large sums will be spent. R. BRIGHTMAN

CLAY MINERALS

X-Ray Identification and Crystal Structures of Clay Minerals
Edited by G. W. Brindley. Pp. vii+345. (London: Mineralogical Society, British Museum (Natural History), 1951.) 35*s*.

THIS is an indispensable reference work for the scientific workers who are trying to bridge the gap between the well-crystallized minerals and those fine-grained and generally less well-ordered ones generically termed clays. Clay was one of the first raw materials to be used by man, and the numerous and sometimes beautiful surviving achievements of early potters in many lands testify to the extensive deposits of useful clay that have been discovered in the past. In Great Britain we have been fortunate in possessing good deposits of kaolinite and of fuller's earth (montmorillonite) that have been known and widely used for centuries. The foundation of the Clay Group of the Mineralogical Society of Great Britain in 1947 indicates a resurgence of interest of scientific men and women in clay and a welcome *rapprochement* of workers from industrial, university, government and other laboratories.

The monograph now under review is the first of its kind to appear in Britain and is a tribute to the inspiration and industry of the editor and his team of French, American and British experts who have given so generously of their time to the collection and dissemination of useful knowledge. Identification is an essential preliminary to all crystallographic studies. X-ray diffraction has proved to be the most powerful method of identifying clay minerals, and due acknowledgments are made to the Bragg school, Ross and Kerr, Pauling, Hendricks and Nagelschmidt for their pioneer work. The value of auxiliary techniques is emphasized, and well-balanced accounts are included of chemical, optical and thermal studies. Mechanical analysis, aided by the centrifuge, is a necessary prelude to the application of X-ray diffraction, chemical and thermal techniques to the quantitative study of clay, soil and ocean deposits. Chapters of a more advanced nature describe crystal structure studies of montmorillonite, halloysite, fireclay and chamosite, and X-ray studies of interstratified and disordered layer lattice minerals. A knowledge of the silicon-aluminium oxygen layer framework and where the layers of water molecules are located can often be extended to a more detailed account of where additional elements—potassium, sodium, magnesium, iron, etc.—are also situated. Thus are explained many of the known properties of clay minerals. It is not too much to expect that more exact crystal structure analyses will lead to the prediction of unsuspected properties, some of which may be useful to science, art and industry.

F. A. BANNISTER

CHEMISTRY OF LIGNIN AND WOOD

The Chemistry of Lignin

By Friedrich Emil Brauns. Pp. xv+808. (New York: Academic Press, Inc., 1952.) 14.50 dollars.

Chemistry of Wood

By Erik Hägglund. Pp. x+631. (New York: Academic Press, Inc., 1951.) 13.50 dollars.

THESE two books have much in common. Each has as author a prominent member of a pulp and paper research organization—Brauns being of the Institute of Paper Chemistry, Wisconsin, and Hägglund of the Swedish Forest Products Research Laboratory—and both authors are prominent authorities on the subject-matter covered. Both books, too, are essentially documentary in character and contain some 2,200 and 1,400 references to the original literature, respectively. Peculiarly enough, the same (and indeed, only) adverse comment applies to both—namely, that they are, if anything, too documentary and perhaps insufficiently critical of the work recorded, including the author's own.

The chemistry of lignin is in effect largely the chemistry of wood, so that overlaps are to be expected and indeed make comparison a matter of some interest. For example, sections on the structure of lignin and its formation and role in the plant are common to the two volumes. Both books adopt an essentially chemical approach to their subject, although the wider industrial implications are duly recognized, even if they are not fully discussed as such. Thus, Brauns emphasizes how the academic chemical approach to the problem of lignin structure via its chemical reactions should lead to the solution of that major problem of all pulping industries, namely, the economic utilization of lignin instead of its disposal as a highly objectionable effluent. Similarly, Hägglund's book has chapters on the chemistry of the acid and alkaline pulping processes used for the manufacture of wood pulp for paper and rayon manufacture.

As might be expected, Brauns's book is the m
restricted in scope although, in consequence, ea
section is correspondingly more detailed. Aspe
covered are the analysis of lignin, its isolation, a
its physical, biological and chemical properties a
reactions, together with its role and formation in t
plant. A long chapter deals, of course, with t
various theories of the structure of lignin. Unf
tunately, it leads to the conclusion that it is premat
to suggest a constitutional formula for lignin, althou
there is strong evidence that lignin is a high polym
comprising at least 75 per cent of phenylpropa
'building stones'. The structure of these 'buildi
stones' and the mode of their combination are, ho
ever, still unknown, and indeed Brauns regards o
knowledge of the structure of lignin as compara
with that of cellulose more than a hundred years a

Hägglund's book is a revised edition of "Ho
chemie", first published in 1928 (second Germ
edition, 1939), now, significantly enough, appear
in English although printed in Sweden and publish
in the United States. The ground covered includ
wood tissue and formation, the physical and chemic
properties of wood and its various constituents, t
chemistry of wood saccharification (Rheinau proces
and the sulphite and alkaline pulping methods a
associated bleaching processes. The carbonizatio
caustic fusion, storage and natural decomposition
wood are also dealt with.

It is noteworthy, and a tribute to both the autho
and publishers, that although the books are print
in Vienna and Sweden, respectively, the standard
production bears very favourable comparison wi
the best of similar books published in Great Britai
These two books, though similar, can be high
recommended as full, authoritative and up-to-da
accounts of our present knowledge of wood and
constituents. On the whole, they are complementa
to, rather than substitutes for, one another; a
studied together they should meet every need of
workers on the subjects of wood and lignin.

JULIUS GRANT

ABSTRACTING FOR PHYSICISTS AND ELECTRICAL ENGINEERS

Physics Abstracts

Section A of Science Abstracts. Vol. 54, 1951. P
vii+1460.

Electrical Engineering Abstracts

Section B of Science Abstracts. Vol. 54, 1951. P
xii+737.

(London: Institution of Electrical Engineers, 195
£2 10s. each section; £4 10s. both sections.

IN 1948 the Royal Society Scientific Informatio
Conference in London discussed among oth
topics the question of improvement of abstracti
services; in 1949 Unesco convened a conference
Paris to discuss the co-ordination of the variou
science abstract journals, and in 1950 the results
an extensive and detailed study, undertaken by t
American Institute of Physics with the financi
assistance of the U.S. Office of Naval Research,
the opinions of physicists on *Physics Abstrac*
(*Science Abstracts A*) were published (*Amer. J. Phys*
18, 417; October 1950. See also *Physics Today*,
18; August 1951). The principal object of the latt
inquiry was to ascertain for what purposes physicis
use abstracts, their opinion of the abstracting servic

available to them and what, within reason, they would like to have in the way of physics abstracting. The result showed that physicists regarded "wide coverage of periodicals" as the primary requirement. "Prompt publication of abstracts", "abstracts written by subject experts" and "extensive indexing" were considered of equal importance but a very poor secondary requirement. Recommendations to implement these requirements were submitted to the management committee of *Physics Abstracts* and were readily accepted. Indeed, it stands to the credit of the editor (Dr. B. M. Crowther) and the committee that nearly all the suggested improvements had been anticipated and in many cases put into effect before the results of the above inquiry were made public. Subscribers to *Science Abstracts* will have noted with satisfaction the considerable expansion and gradual improvement generally of both *Physics Abstracts* and *Electrical Engineering Abstracts* (*Science Abstracts B*) during the past few years.

Commenced in 1898 when it was the first journal of its kind, *Science Abstracts* is now the major abstracting journal covering articles with a physical interest in mathematics, astronomy, astrophysics, geodesy, physics, physical chemistry, crystallography, geophysics, biology, technical materials and photography in Section A, and articles of interest to electrical engineers in engineering, electrical engineering, electronics, telecommunication and technology in Section B. The journal is controlled by a management committee consisting of council members of the Institution of Electrical Engineers, the Physical Society, the Royal Society, the British Electrical Authority and an observer from the American Physical Society. The executive officers are the Secretary of the Institution and the Editor of *Science Abstracts*. Facilities and administration are provided by the Institution; but the financial responsibility is borne jointly by the Institution and the Physical Society. The circulation of Section A is very large, greater than 12,000. Until quite recently more than half the number of copies sold were purchased by the American Physical Society for distribution to its members automatically as a privilege of membership and without extra cost; every member of the Physical Society receives a copy; a copy for personal use may be purchased at a considerably reduced rate by members of the Institute of Physics and members of the Institution; and a large number of copies are sold to the general public, mainly libraries and organizations. Though Section B, with a circulation of 4,000, has not such a wide appeal as Section A, its circulation is still quite good. It could, however, be improved among physicists, for more than half the copies issued are distributed to members of the Institution and a large part of the remainder sold to libraries and organizations.

The price of *Science Abstracts* is remarkably low, and although it has had to be raised recently, the increase is by no means in proportion to the expansion in the journals which has taken place since 1945. For example, the 1951 volumes (*A* and *B*) contained 9,908 (1160 pages) and 4,650 (624 pages) abstracts respectively and indexes covering approximately 300 and 100 pages respectively, whereas in 1945 the corresponding figures were 3,148 (339 pages), 2,744 (292 pages) and indexes of approximately 60 and 50 pages respectively.

The corresponding increase in price, however, has been only about 50 per cent. Furthermore, the time-interval between the appearance of an article and the publication of the abstract in *Science Abstracts* has been reduced considerably. The speedy publication of the annual indexes is most important, and before the Second World War the annual indexes appeared regularly in February. For many years since, however, this was not possible and when, therefore, in 1950 the pre-war practice was resumed many people doubted whether it could be maintained. However, they were to receive a pleasant surprise, for the annual indexes for 1951 were distributed to subscribers in mid-January 1952, a feat of which the editor and his staff must feel justly proud.

It is difficult to review Vol. 54 of Sections A and B without making a few comments and suggestions, though admittedly these are of minor importance and are naturally the reviewer's own personal views. It is irritating to find only a supplement to the list of journals abstracted at the beginning of Vol. 54 and to have to refer to an earlier volume for the main list. Books, in addition to articles in scientific journals, are sometimes abstracted, but it is difficult to ascertain on what basis these books are selected, and in any event how does one abstract a book? The varied styles of the book abstracts reveal some of the difficulties the abstractors have had in this regard, whether to go to the one extreme of a review or the other extreme of a mere copy of the contents list. There are still too many abstracts in which the title of the article is repeated as the opening sentence, though this fault is more or less confined to author abstracts. The onus here is really on the editor of the journal in which the article abstracted appeared; but it perhaps would be a good thing if *Science Abstracts* were ruthless in revising such abstracts. Referees of scientific papers should be encouraged to comment on the abstracts as well as on the contents of the papers submitted to them.

The remarkably few misprints, the clear type and lay-out of the abstracts, the detailed author and subject indexes and the ease with which one can find one's way about the abstracts, in addition to the consistently high standard of the abstracts and arrangement, are praiseworthy features. The Universal Decimal Classification system of classification is excellent for arrangement, but it is doubtful whether the time and labour involved in printing the U.D.C. numbers is worth while. Complete coverage of all periodicals is, however desirable, obviously impracticable, and the close co-operation between the various abstracting journals to make use of each others' abstracts is to be encouraged. *Science Abstracts* now includes many abstracts prepared by other abstracting journals.

In accord with recommendations of the Royal Society the abstracts are "written concisely and in normal rather than abbreviated English", but abbreviations of words are used and in some cases these may not be familiar to the reader; for example, a physicist may not recognize that 'o.h.' stands for 'over-head'. So far as possible, abstracts should be easily read and should be self-explanatory, so that abbreviated words (except, of course, recognized units) should be avoided. There remains but one last comment and plea. If the editor of *Science Abstracts* sees fit to increase still further the number of abstracts a year in *Physics Abstracts*, he is asked to bear in mind that *Abstracts A* is now as large as can be conveniently bound in one volume and that if it were bound in two separate parts, though naturally more costly, it would be easier to handle, and the binding would not be so highly strained. S. WEINTROUB

SCIENTIFIC THOUGHT THROUGH THE AGES*

By Dr. NAZIR AHMAD
Chairman, Pakistan Tariff Commission

THE rudiments of scientific thought must have started as soon as man began to think for himself. When he saw the natural phenomena with which he was surrounded, the rising and setting of the sun, the phases of the moon, the twinkling of the stars, the rain, the wind, the lightning, the change of the seasons, the growth of plants and crops, he must have begun to wonder about their causes; and that wonder was the starting point of the scientific thought in him—the seed from which the tree of knowledge was ultimately to grow. In the distant past, man tried to reproduce natural phenomena by imitating Nature. He conceived the idea that if he imitated any aspect of Nature, he would be able to reproduce it. For example, he associated the croaking of frogs with the oncoming of rains; and he concluded that, if he imitated the frogs, he might bring down rain on earth. There are numerous instances of such imitation on the part of early man with the object of reproducing natural phenomena, which have come down to us in the form of dances and rituals. This attempt on his part to reproduce natural phenomena by imitation led to what is now called 'imitative magic'. This form of magic, associated with what is known as 'contagious magic', was man's earliest attempt, in a crude way, to comprehend and explain some of the natural phenomena. However, whether it was 'imitative magic' or 'contagious magic', it was slowly transformed either into scientific thought, when an effort was made at a rational explanation, or into a religious belief, when natural phenomena were explained in terms of deities, gods and goddesses or a supreme being. According to one school of anthropologists, magical conceptions led to religious beliefs on one hand, and scientific thought on the other; while a second school of anthropologists holds the view that the transition was from magic to religion and from religion to science. Be that as it may, this intermingling of magical concepts and religious beliefs with scientific thought, which started right in the beginning, remained one of the dominant features for many centuries; and was, and perhaps still is, responsible for the slow victory of rational thought over superstition and out-moded belief.

Coming to the development of scientific thought, as we understand it to-day, we find its rudiments in the civilization of Babylon, where their mathematicians developed a mixture of the duodecimal and decimal systems—from the ten fingers and two hands; and, because the number 60 was the first common multiple of 10 and 12, it acquired a special significance, which it has managed to preserve even to the present time. It is from there, indeed, that we get divisions like 60 seconds to a minute, 60 minutes to an hour, 60 seconds to a minute in the measurement of an angle, etc. With this useful discovery of the rudiments of arithmetic, magical ideas got strangely inter-woven; this retarded the progress of scientific thought, especially when the Chaldean astrologers acquired the upper hand. Apart from this discovery, the Babylonians were the first to undertake the cultivation of cereals; this compelled them to devise some kind of a calendar, which is one of the earliest in the world. From their astronomica observations, they were able also to calculate the relative positions of the sun and the moon, and predict solar and lunar eclipses; but, instead of pushing forward the bright science of astronomy they turned aside into the dark regions of astrology and evolved a curious conglomeration of both.

From Babylon the scientific development passes on to Egypt, where we find the first use, on a large scale, of the wheel as a scientific tool. Great stride were made in the science of land measurement, because when the River Nile, which is the life-line of the Egyptian cultivators, was flooded, the fields and the farms got terribly mixed up; and the Egyptians found that the science of land measurement was necessary to enable them to know to whom a particular plot of land belonged. Apart from these advances, other great advances, for which the old Egyptians were responsible, were in the fields of physiology and surgery, which resulted from their art of mummification. They, for the first time, performed fairly complex surgical operations, and discovered certain physiological principles. Contemporary with the civilization of ancient Babylon and Egypt was the civilization of India, where memorable advance was made in the theory of numbers; in fact, where for the first time the numerals one to ten, as we know them, were used extensively, which later on were taken by Arabs from India and passed on to Europe, and hence they came to be known as Arabic numerals. In India, the science of medicine also made fair progress—especially under the influence of the Buddhistic teachings, which laid great emphasis upon love, fellow-feeling and sympathy. But the advancement of science and the progress of scientific thought in India were retarded by the conflict with such philosophical concepts as the transitoriness of earthly existence and the evanescence of life. The Indian philosophers were more concerned with the life hereafter, and they regarded life on this earth as *maya*, a shadow, a fleeting moment, which did not deserve serious consideration.

Such was the intellectual background of the civilizations of ancient Babylon, Egypt and India, until the blossoming of scientific thought, as we understand it, took place in Greece about the fifth century B.C. The ancient Greeks revealed themselves as amazing people with an unquenchable thirst for truth; and the freedom of thought witnessed among them had not been equalled anywhere before their time. Indeed, their freedom of thought was so unfettered that their great dramatists wrote satires and comedies on subjects which the common people venerated; and these were actually produced on the stage. This freedom of thought among the ancient Greeks was one of the motivating forces for their great scientific and philosophical advance. Pythagoras was the first philosopher who developed the abstract idea of numbers, which he probably took from the ancient Indians, as he was acquainted, to some extent, with their philosophy. He was also responsible for the concept of four primary elements hich constituted the basic materials for all the other ountless objects of this world; these four elements eing earth, water, air and fire. The Greeks were he first people who paid serious attention to the roblem of matter; and tried to find out whether he great variety of objects, which constitute the naterial world, could be explained in terms of a ingle element. They were not successful in this ynthesis because their efforts were more flights of magination than scientific theories based upon solid lata. However, in this process, a group of philoophers, known as Atomists, rose among them, who, y a wonderful insight, were the first people to express he idea that matter is ultimately made up of small articles, which they called 'atoms'. The philosopher rho gave the final touches to this hypothesis was emocritus, and his exposition has been handed own to us in a fine poem by Lucretius. However, he hypothesis was not supported by any experimental facts, as was the case with Dalton's hypothesis nany centuries later; and therefore, when it was ttacked by other philosophers, like Plato and ristotle, it could not withstand their criticism.

---

* Substance of a public lecture given before the Fourth Pakistan Science Congress at Peshawar on March 17.

Nevertheless, the philosophical inquiries, which rere begun by the early Ionians, were pushed forward ntil we come to Socrates who, for the first time, egan to question openly and relentlessly beliefs and leas commonly held by his contemporaries. He did ot originate any system of philosophy; but he was he founder of what is called the Socratic system by rhich beliefs, notions and views commonly held by eople are analysed and cross-examined until one egins to see the fallacies underlying them, and thus he ground is prepared for building a more stable tructure. His work was carried a step forward by is great pupil, Plato, who, however, denied reality o individual objects, and put forward the view that bjects, as we see them, are unreal because they are ontinually changing; while reality lies in abstract types', of which the visible objects are mere shadows. Because of his emphasis on 'reality' in certain 'ideal' ypes, Plato's philosophy is sometimes known as Realism and sometimes as Idealism. This philosophy ctually proved a setback to the development of cientific thought, because it took man's attention rom nearby objects on earth, and riveted it upon bstract and ideal types, which existed only in magination.

Reaction against Plato's philosophy occurred soon n the teachings of his famous pupil Aristotle, who ut forward the idea of dual reality, according to rhich a certain measure of reality attached itself to he individual objects, though the thoughts and ideas rhich the human mind perceived from those objects rere also equally real. This dualism in reality, which ristotle postulated, helped to bring back men's ninds to the objects of this earth for scientific study; nd it persisted in the philosophical field, in one form r another, for centuries until it blossomed forth in he teachings of Immanuel Kant. However, Aristotle's reat achievements were not in the fields of physics, nathematics or astronomy, in which he held rather antastic notions, but rather in the fields of medicine nd deductive geometry, in which he made notable ontributions. His success in deductive geometry led im to found deductive logic, in which one argued rom general principles to particular cases. The eductive logic, which really represents half the icture, was, to Aristotle's mind, almost the complete ogic; and he applied it vigorously to the explanation f natural phenomena, with the result that he was responsible for several fallacies, which, under the weight of his authority, persisted for many centuries. He was also responsible for the rejection of the atomic theory, as propounded by the early Greek Atomists; and he went back to the ideas of the Pythagorean school that all matter is ultimately made from four primary elements. However, he went a step further, and instead of defining the so-called elements in terms of earth, air, water and fire, he defined them in terms of four primary qualities, namely, hot, cold, wet and dry. He developed the theory that these four cardinal qualities, in their various combinations in different quantities, were responsible for the numerous objects which we see around us. Some reaction against Aristotle's philosophy was set in motion by Epicurus, who taught that 'reality' is essentially sensation and sense-perception, and thus tried to turn man's attention to the study of objects as one became aware of them with one's senses; but unfortunately the finer aspects of his philosophy were submerged in a baser interpretation, and the theory failed to achieve its objective.

As against these great philosophers, who freely mixed scientific thought with philosophical notions and scientific observation with flights of fancy, we have the brilliant example of a true scientist—Archimedes—who did not begin with any preconceived philosophical notions, but approached Nature from the point of view of an experimental scientist. He was the founder of the science of mechanics, the discoverer of the principle of the lever, the designer of engines of war which kept a numerically superior army at bay; and in his various researches he showed the scientific spirit by going cautiously from step to step and proving the validity of every step he undertook. The ancient world holds few examples of such marvellous combination of the qualities of imagination, deduction and verification as shown by Archimedes, who fell under a Roman sword.

After Archimedes the study of science shifted mostly to the famous school of Alexandria, which contained well-organized sections devoted to the advancement of biology, physics, chemistry, mathematics, etc. But the greatest strides in this school were made in astronomy; and it was there that for the first time the old notions about the movements of the earth and the heavenly bodies were examined, and a working theory known as the Ptolemaic system, in which the earth was made the centre of the universe, was put before the world. In spite of its obvious drawbacks and complicated explanations, this theory held the field for several centuries for two reasons. In the first place, it made man and his abode the centre of the universe, which greatly pleased his vanity. Secondly, it was considered to be in accord with the teachings of the Scriptures, and in fact enjoyed the blessings of the Christian Church. We have here another example of the way in which a scientific theory can get mixed up with personal considerations and religious conceptions, and derive its strength not from scientific data but from the backing which an extraneous agency can give to it.

After the rise of the Roman Empire, the service of science naturally passed on to the Romans; but one has to confess that very little advance was made by them in the fundamental sciences. They were a practical people, and they concentrated on applied science, such as agriculture, engineering and irrigation, while neglecting in general the study of pure science. A notable exception, however, was the famous physician Galen, who, though of Greek origin, flourished in Roman times, and who made substantial contributions to the sciences of physiology and medicine.

The fall of the Roman Empire was followed by a long period of decline of learning in Europe, attributed generally to the hostility which the organized Church offered to the Greek learning handed down to the people. According to the teachings of the Church at that time, the ultimate 'reality' was spirit and the ultimate values were spiritual; and, therefore, any study which took away people's minds from spiritual values and the ultimate 'reality', namely, the spirit, was to be eschewed. As a result of this attitude, the so-called Dark Age descended upon Europe and lasted for nearly four hundred years. At this time the torch of learning was, however, grasped by the Arabs, and it was kept aloft by them, burning brightly. The first task of the Arabs, when they took over the service of science, was to re-discover the hidden treasures of Greek learning. They translated the books of Greek philosophers and scientists, Plato, Aristotle, Galen, Hippocrates and others, and wrote commentaries upon them. But that was not all. They went far beyond it. They made very considerable progress in almost all the different branches of science. In chemistry, led by the motive of discovering the elixir of life, they made great strides. Their knowledge of the human body and the functions of its various organs excelled the past, and they went far ahead of the Greeks in medicine. In mathematics, they founded a new branch known as algebra. In physics, especially in optics, they made very remarkable original contributions. They made accurate charts of the heavens, and navigated the seas as had never been done before. But in spite of these original contributions to different sciences, the underlying scientific thought remained largely Aristotelian. Deductive logic held the field, and the Arab scientists and philosophers had only a vague conception of the principles of inductive logic; so that, like the Greeks, they also argued from the general to the particular. They accepted many Grecian fallacies, and did not bother to perform experiments to verify them. In one essential respect, however, Arab thought differed fundamentally from the Greek point of view. The Greek conception of the universe was more static than dynamic; they were inclined to regard the universe as a complete entity in which no fundamental change was possible. Many of the Arab philosophers, on the other hand, took a dynamic view of the universe, which, according to them, was constantly undergoing change and development, even by a process of trial and error.

Among the many Arab philosophers who made a real contribution to scientific thought the name of Ibn-i-Rushd, known in Europe as Averroes, stands out prominently for a remarkable thesis on the relationship between religion and philosophy. He stated that religion was essentially a personal experience, which could not be demonstrated; while science, on the other hand, was knowledge the results of which could be demonstrated by one man to another. He further pointed out that theology was a mixture of religion and science, and as such a source of evil to both, because it corrupted religion with pseudo-science and imposed fallacious notions on science in the name of religion. It is a great pity that this profound lesson, which was taught by Ibn-i-Rushd nearly a thousand years ago, has not been fully appreciated by later thinkers, especially in Islamic countries, where the tendency to superimpose one branch of knowledge upon the other persists to the detriment of both. Another thinker who exercised a great influence on the development of scientific thought in the Muslim world was Ghazali, who was considered a master of learning in his time. He was originally a professor of philosophy in the Nizamia University, but when he saw the shortcomings of the Aristotelian deductive logic, he became disgusted with it; and without realizing that the Aristotelian logic, as inherited by the Arabs, was incomplete and, therefore, unable to explain all or even most of the phenomena, he turned his face away from it, and launched a vigorous attack upon philosophy and science in general. His forceful personality and wide learning carried great weight with his contemporaries; and his attack upon philosophy is regarded by some people as the beginning of the decline of philosophical and scientific studies in the Muslim world. In any event, the pendulum swung in the other direction, and in the thirteenth century the pursuit of learning and development of scientific thought passed again to the Western countries.

This revival of learning in Europe at this time took a curious shape. The hold of the Church on the people was still very strong, and full freedom of thought and expression was not permitted. But, as the writings of the Greek philosophers, especially of Aristotle, and the contributions of Arab philosophers were studied, it was found that they contained many ideas and notions which went against current thoughts and beliefs. As these contradictions between the two accepted authorities created intellectual conflicts, St. Thomas Aquinas tried to harmonize the religious concepts of the time with the postulates of Greek learning as handed down to Europe by the Arabs. This notable attempt at reconciliation of religious concepts with philosophical ideas, called Scholasticism, held the ground for more than two centuries. Such attempts are not peculiar to Europe; they have been made in other countries as well. In the history of Islam, similar attempts were first made by the M'otazalin in the early days of the Abbasid Caliphate, later by the Mutakallimin, still later by Ibn-i-Tameea and his disciples, and even in our own time it is being made by many people.

However, in Europe, there were a few thinkers who saw that this attempt at the synthesis of religious beliefs with scientific thought was not always successful. Notable among them was Roger Bacon, who was one of the first to realize the ineffectiveness of this approach. According to him the four great obstacles to learning were: (1) regard for authority; (2) force of habit; (3) prejudice; and (4) false conceit of knowledge. It is really remarkable that a man, who lived nearly seven hundred years ago, was able to put his finger precisely on the principal causes which can hold back the advance of learning in any age. Due to the writings of men like Roger Bacon and others who followed him, Scholasticism gradually declined in Europe, and gave birth to the Renaissance in the fifteenth century. A great deal has been written upon the revival of learning in Europe, in which science ultimately comes into its own, and parts company, on one hand, with philosophy and, on the other, with religion. But we must not forget that, apart from the intellectual activity, which was going on at that time, there were certain material factors which helped considerably the Renaissance ovement in Europe. These were, first, the use of per, originally invented in China, which made arning more accessible to the masses. Secondly, ere occurred at that time the invention of printing, ducing greatly the laborious art of writing books hand, which could thus reach thousands instead hundreds of people. Perhaps even more important an these two factors was the development of the ience of navigation, in which the Arabs had made eat progress and which was learnt from them first the Portuguese and the Spaniards, who happened come in greater contact with them. The development of navigation opened up new lands to European tions, which not only stimulated their imagination it also increased their power and material prosrity. The judicious investment of surpluses enabled em to make still larger profits, and the wealth thus rned gave a tremendous impetus to the expansion trade and industry.

As a result of the intellectual activity of men like oger Bacon, assisted by the impact of physical rces like the invention of printing, and the accelered means of communication and contact, Europe oduced a number of thinkers who can be regarded the precursors of modern scientific thought. One the first great figures among them is Leonardo Vinci, who although not responsible for any great ientific discovery himself was yet able to demolish large number of fallacies by approaching each bject with an open mind. His approach to any fficult subject was generally from the practical side. hen he formulated a theory, he first tried to test it making models. He made models of tanks, aeroanes, and even submarines. These, of course, were workable, because his knowledge of detail was sufficient; but they go to show his eminently actical approach, so essential to scientific progress. e then have Copernicus, who studied the planetary otions carefully, and found that the geocentric eory of Ptolemy was not able to explain these otions so easily and elegantly as the heliocentric eory. This discovery was a great blow not only to cient learning, but also to the attempts made to haronize scientific thought with religious beliefs. About e same time came Harvey, who discovered the rculation of the blood, and, thereby, upset another eat fallacy—the fallacy of 'humours'—which had evailed among men of science since the time of the reeks. The same period saw Gilbert, the father of agnetism, who by his researches helped the further evelopment of navigation, and who gave us new eas regarding terrestrial magnetism.

Along with these experimental scientists, who went demolishing one fallacy after another with their iscoveries, we have Francis Bacon, who formulated early the principles of inductive logic. In his ritings he stated that the task of a philosopher is e collection of facts, the formation of a hypothesis, d the verification of the hypothesis by further perimentation and observation. For the first time e principles of inductive logic were clearly stated; nd as if to show that the hour was ripe, great ientists like Kepler, Galileo and Newton appeared the scene, and made noteworthy advances in the fferent sciences by the practical application of these rinciples. Kepler took Tycho Brahe's carefully llected data and deduced three famous laws of lanetary motion, thus exemplifying the first two rinciples laid down by Francis Bacon. Galileo was living example of the inductive method personified one man. He approached his manifold problems with a perfectly open mind. He would start by collecting as many facts as possible, often making wonderful improvizations, such as using his pulse for recording the movements of a pendulum. When sufficient data had been collected, he would draw a hypothesis from them, but he would not be satisfied with it. He would go a step further, and draw conclusions from his hypothesis which he would test by further experiments. If the conclusions were not confirmed by the results of his experiments, he would abandon the hypothesis and start afresh. His greatest contributions were in the fields of dynamics and astronomy, though he left his mark on other sciences as well.

The year of Galileo's death coincided with the birth of the greatest scientist of the seventeenth century Newton. His contributions in the fields of astronomy, optics, mathematics, mechanics, etc., are so many that it is not possible even to summarize them here. His discovery of the law of gravitation alone, which seemed to apply from the macroscopic to the microscopic, was monumental. The discovery of the differential calculus placed a powerful weapon in the hands of the mathematicians. The mechanics, which came to be known by his name, became the framework in which all new discoveries for the next two centuries fitted so well, and in which no chinks were observed until the theories of quanta and relativity made their appearance on the scene. More important than all, Newton's work and the discoveries of his successors helped to give science a philosophy of its own in the succeeding centuries.

The eighteenth century saw discoveries in practically all the branches of science. They helped to upset many old fallacies that had persisted up to the time, and they laid the foundations for the great scientific theories which were to follow. In mathematics, Laplace took Newton's work further and also attempted a theory of the cosmos. In chemistry, the outstanding work of Lavoisier ended the false concept of 'phlogiston', and thus laid the foundations of the modern theory of heat. Another fallacy of the old times, namely, that water was one of the four elements, was thrown overboard by the work of Cavendish, who showed that it could be split up into gaseous elements, namely, oxygen and hydrogen. There were, similarly, advances and discoveries in the fields of botany, zoology and physiology, too numerous to relate, but all of which helped to give a clearer and truer picture of Nature to man. As a result of the success with which Newtonian mechanics was able to explain numerous phenomena of Nature which were apparently not connected with one another, and as a consequence of the great discoveries which were made one after the other in the different branches of science, the belief grew stronger that the universe was governed by fixed laws; that it was possible to discover these laws with the help of science; and that ultimately science would be able to explain all natural phenomena including man himself. This belief in the rigid working of the laws of cause and effect, which could be discovered by scientific research, gave birth to the school of thought known as determinism or materialism. However, while the scientific discoveries in the eighteenth century were giving enormous confidence to scientists in the efficacy of the scientific method in explaining natural phenomena, the philosophers were not idle, and they attempted to show the shortcomings of this particular line of approach. Locke emphasized the necessity for continual adaptation to varying needs and requirements of the time; and, thereby, inculcated a healthy scepticism against any fixed outlook. Berkeley reacted strongly to the materialistic view held by some of the scientists, and denied reality to matter. Hume went one step further and denied reality even to mind. Immanuel Kant, however, took a middle course, and attempted a synthesis of scientific discoveries with philosophical concepts in which, while admitting the necessity of the study of Nature by observation and experiment, he tried to show the limitations of the knowledge gained in this fashion.

The cautious or even negative approach of philosophers like Kant, Berkeley and Hume, however, could not stem the great tide of scientific discoveries, which continued with ever-increasing force and widening scope in the nineteenth century, which may be called the 'scientific age'. Since reliable experiments could not be performed without exact units of measurements, a great deal of work of fundamental importance was done on the primary units of length, mass and time, and the secondary units derived from them. Dalton tackled the problem of the ultimate constitution of matter, and, reviving the work of the ancient Greek Atomists, built up the ground floor of the modern atomic theory in which subsequent advances in chemistry were made. A great deal of work was done on the imponderable fluids, namely, the ether, electricity and heat, and the phenomena connected with them. Young, Fresnel and Huygens revived and developed the wave theory of light, which had been suppressed by Newton's opposition and which postulated the existence of an all-pervading ether. Faraday took up the study of electricity and magnetism, and not only brought about revolutionary changes in our concepts, but also made possible the tremendous advances in electromagnetism which took place after his time. Clerk Maxwell developed the electro-magnetic theory of light, which bridged the gulf between electricity and light, and thus acted as a brilliant pointer to the ultimate oneness of scientific knowledge. Joule, by his researches on the relationship between heat and work, laid the foundations of the modern theory of thermodynamics, which was taken many stages further by Carnot. These discoveries in the experimental and theoretical fields no doubt produced deep changes in the scientific outlook, and confirmed the earlier confidence of the eighteenth century in the ability of science to explain all natural phenomena. None of them, however, produced such revolutionary currents of thought as Darwin's theory of evolution, which by its nature and implications came into conflict with the current theological ideas on such fundamental questions as free-will and moral behaviour.

The relationship between science and philosophy has been undergoing a remarkable change. In the beginning, as a legacy of the Scholastic School, philosophy dominated science. The philosophers, with their training for the search of 'reality' and with their ability for analysis of material phenomena and mental processes, took the leading place. They attempted to synthesize scientific discoveries into complete systems. Later on, however, science and philosophy parted company. The separation became pronounced after Hegel, who under-rated the role of experiment and taught that 'reality' could be achieved by abstract thought. Science could not accept this position without sacrificing some of its great principles and discoveries. Still later, science attempted to develop a philosophy of its own, the first attempt of the kind being made by Ernest Mach. The attem on the part of science to have its own philosophy h been stimulated greatly by discoveries in the field biology. So far a great majority of the revolutiona discoveries had been in the field of physics, chemistr astronomy and mathematics, which did not seem have a deep impact on life or on man's concept himself. But Mendel's laws of inheritance, t statistical study of heredity, and the biophysical a biochemical discoveries which took place in t nineteenth and twentieth centuries had a profou effect on scientific thought. The construction of lar telescopes, which took man's vision into the dista reaches of the skies, and the manufacture of micr scopes, which gave him an insight into the constit tion and function of the micro-organisms borderi on the molecules, gave further support to science developing its own philosophy. All these discoveri strengthened belief in the ability of science to sol ultimately the mystery of matter, energy and li with analytical methods based upon Newtonis mechanics.

When we come to the twentieth century, howeve the picture begins to assume a somewhat differe shape; and the tremendous confidence of the nin teenth century is assailed by many doubts a uncertainties. We have first the discovery of t quanta and the development of the quantum theor which represents a break with Newtonian mechanic We then have the discovery of the electron, t behaviour of which could not be explained on t classical lines. Then came the development of t theory of relativity, which rejected the concepts absolute time and space. The hard indivisible ato was found to be a small world, with electro revolving around a nucleus, while quantum mechanic and not the classical mechanics, was able to expla the phenomena of radiation emitted by atoms in t excited state. Even so, the explanation, if it can called one, was partial; for an element of uncertaint seemed to be inevitable, and became greater t more we probed into the innermost nature of matte The epoch-making discoveries of J. J. Thomso Rutherford, Röntgen, Curie and Becquerel, and t theories of Planck, Einstein, Niels Bohr, Schrödinge and others, while enlarging our vista a hundred-fol unfolded a thousand new problems. Radiatio presented a double-faced appearance. In certa respects it behaved like continually expanding waves in others like discrete particles of energy which ke their entity regardless of time and distance. Ultim ately, in the hands of Heisenberg, even materi particles remained no more than wave systems. Now all these discoveries of the twentieth century whic deny the existence of absolute time and space, whic inform us that we can either determine the motio of an electron or its position but not both, which te us that change is not always continuous but ofte takes place by fits and starts, which state that w know what happens when an electron jumps fro one orbit to another, but we do not know wha happens to it in the meantime, which advise us tha matter and energy are interchangeable and that bot can be represented by wave-systems—these hav re-orientated our attitude towards that determinis which characterized the eighteenth and nineteent centuries. Some scientists are now not so sure tha scientific method alone can solve all the mysteries c life, or can be successful in giving us a perception o the 'reality'. But, notwithstanding these misgivings we may say in the words of Sir William Dampie at, “in spite of ignorance, folly and passion, the ientific method has won field after field since the ys of Galileo. From Mechanics it passed on to hysics, from Physics via Chemistry to Biology, from iology to Psychology, where it is slowly adapting self to unfamiliar ground. There seems no limit research, for as has been well and truly said, e more the sphere of knowledge grows, the rger becomes the surface of contact with the nknown”.

This brief survey has revealed three salient features. the first place, the spirit of inquiry, which is ssential for scientific advance, is latent in the human ind. This spirit of inquiry has made its appearance different times, in different lands and among ifferent peoples. Secondly, this seed will not grow, is spirit will not blossom, in an atmosphere of ppression, inhibitions and restrictions. It must ave freedom—freedom to think, freedom to speak, eedom to discuss, freedom to exchange ideas with thers. If restrictions are imposed upon it, if it is ttered with chains, which may be those of authority, perstition, habit or prejudice, the spirit of inquiry ill remain dormant, and ultimately it may even be xtinguished. In order that the spirit of inquiry implanted in our souls may blossom fully and flourish, freedom of thought, freedom of speech and freedom of expression are essential. Science can recognize only its own ideology. If attempts are made to impose any other ideology upon it, it can only be to the detriment of scientific advance and progress. The third salient feature which should be apparent from this historical survey is that all attempts to formulate a comprehensive system, aimed at explaining everything, have failed in the past when human knowledge was not so vast. Now that the bounds of knowledge have been vastly extended, such attempts, if made now or in the future, are bound to be even bigger failures. Those who claim to offer comprehensive systems, complete in themselves, as explanations for everything there is to be explained, are ignorant of the nature and extent of our knowledge; and unless they are themselves mistaken, they are attempting to mislead others. Although all knowledge is fundamentally interlinked, progress is possible by making advances on its different sectors. This progress, though it may not be spectacular, is sure and certain. Only thus may we look forward to the gradual lifting of the mists which hide ‘reality’ from our vision.

NEWS and VIEWS

ew York Zoological Society

A NUMBER of changes in the staff of the New York oological Park have been recently announced by he New York Zoological Society. The title of director f the Zoological Park, vacant for a number of years, as been revived by the appointment to that position f Mr. John Tee-Van, executive secretary of the Zoo nd Aquarium since 1942. Mr. Tee-Van, who has een connected with the Zoological Society for forty-ne years, started work as an assistant keeper in the ird Department in 1911, at the age of fourteen, and ve years later became an assistant in the new epartment of Tropical Research, working with Dr. illiam Beebe in research stations in the West Indies, ritish Guiana, Venezuela, the Galapagos Islands, he Sargasso Sea, Haiti, Bermuda and off the coasts f Lower California, Mexico, Central America and olombia. His scientific work has been done chiefly n ichthyology, a field in which he has published many apers, and he is a vice-president of the American ociety of Ichthyologists and Herpetologists. Since 940 Mr. Tee-Van has been editor-in-chief for a series f books on “Fishes of the Western North Atlantic”. e is a fellow and recording secretary of the New ork Academy of Sciences, a member of the Boone nd Crockett Club and president of the Explorers lub.

Other changes are as follows. Dr. Leonard J. Goss, eterinarian since 1939, has been made assistant irector of the Zoological Park and will continue as eterinarian. Mr. Lee S. Crandall, general curator ince 1943, is retiring from active administration of he mammal and bird collections, although he will ontinue to maintain an office at the Park and will e engaged in the preparation of books on the care, eeding, maintenance and exhibition of wild animals n captivity, based on his experience of forty-four ears with the collections of the Bronx Zoo. Mr. obert M. McClung, who has been assistant curator of mammals and birds under Mr. Crandall since 1949, has been appointed acting curator of the department. Mr. McClung is a graduate of Princeton and Cornell Universities and is the author of several animal books for children. Dr. William Beebe, who is retiring with the title of director emeritus of the Department of Tropical Research, is the only member of the staff of the Zoological Park who was connected with it before the actual opening of the Zoo in 1899. He was curator of birds during 1899–1920 and since then has been director of a separate Department of Tropical Research, under which field-stations have been maintained in many parts of the American tropics, and oceanographic work in both the Atlantic and the Pacific has been undertaken. One of Dr. Beebe's best-known exploits was the descent in the bathysphere to the record depth of 3,028 ft. off Bermuda on August 15, 1934. Dr. Beebe expects to go to Trinidad later this year and to resume research in the ecology of the Arima Valley, on which he has been engaged for the past two years. Miss Jocelyn Crane, a member of the staff of the Department of Tropical Research since 1930 and research zoologist since 1942, has been made assistant director of the Department. Miss Crane, who is a graduate of Smith College, is at present engaged in a study of the biology and behaviour of various invertebrates and sense perception in insects.

Jacobus Henricus van't Hoff (1852–1911)

ONE of the founders of modern physical chemistry, whose work also profoundly influenced physiology, biology, geology and mineralogy, Jacobus Henricus van't Hoff was born at Rotterdam a century ago, on August 30, 1852. Educated at Delft, Leyden, Bonn and Paris, he obtained his doctorate at the University of Utrecht in 1874, after having already published a pamphlet which laid the foundations of stereochemistry. An amplified version in French, “La chimie dans l'espace”, appeared in 1875. Van't Hoff showed that optical activity and the existence of two optically active isomers, differing merely in the sign of their rotations, occurred only when an asymmetric carbon atom was present. A short period as *Dozent* in physics at the Utrecht State Veterinary School was followed by a move to Amsterdam, where at the age of twenty-six he became professor of chemistry, mineralogy and geology at the newly created University. In his classic "Études de dynamique chimique" (1884) he successfully applied the laws of thermodynamics to the problems of chemical equilibrium and affinity, and two years later he evolved his famous theory of solutions, which helped to develop the theory of electrolytic dissociation and modern electrochemistry. In 1896 he accepted a research professorship in chemistry at the Royal Prussian Academy of Sciences in Berlin. Among his many-sided investigations his study of oceanic salt deposits inaugurated a new era in experimental mineralogy. His numerous honours included the Nobel Prize for Chemistry (1901), the foreign membership of the Royal Society (1897) and the German order *Pour le mérite*. Van't Hoff was a simple, friendly person, the last years of whose life were clouded with illness, necessitating periods of rest in sanatoria. He died at Steglitz on March 1, 1911.

Pharmaceutical Society : Research and other Awards

THE Pharmaceutical Society has awarded its research scholarship of £300 a year for two years to L. E. Coles, who will be engaged in the School of Pharmacy, University of London, in completing work on the synthetic analogues of the adrenal cortical hormones. Wellcome Pharmaceutical Research Fellowships, each of £350 a year, have been awarded to J. Thomas, for work in the Department of Pharmacy, University of Manchester, on the chemical synthesis of biological activity, particularly bactericidal action, of a new series of quaternary ammonium compounds, and to G. L. Willey, for research at the University of Leeds on the possibility of selectivity of action of nicotine-like stimulant compounds. The Society also made the following awards : Jacob Bell Memorial Scholarship (£150 with £5 worth of books), to T. M. French, of Northampton ; Manchester Pharmaceutical Association Scholarship (£45), to R. A. Alcock, of Ormskirk ; and the Devon and Cornwall Exhibition in Pharmacy (£25), to A. James, of Tiverton.

Courtauld's Scientific and Educational Trust Fund : Awards

THE trustees of the Courtaulds' Scientific and Educational Trust Fund have announced the award for 1952 of the following postgraduate research scholarships in a branch of science related to the textile, plastics and allied industries, which are worth £375 (except where otherwise stated) and are tenable for one year at the institute shown : D. W. Bannister and P. T. Speakman, University of Oxford ; H. W. W. Brett, University of Adelaide ; C. S. Chadwick, Manchester College of Technology ; E. S. Hill, University of Liverpool ; J. W. Ladbury, Imperial College of Science and Technology, London ; D. C. Blackley (renewal of 1951 award), C. J. Pearce, B. D. Stead and C. N. Turton, University of Birmingham ; J. Russell (renewal of 1951 award), Bradford Technical College ; J. Saunders (£93 15*s*., renewal of 1951 award for autumn term only), University of Bristol ; A. E. Somerfield (renewal of 1951 award), Trinity College, Dublin. Postgraduate researc scholarships in textile technology, worth £300 a yea for two years, have been awarded as follows : I Attle and S. L. Fitton, Manchester College o Technology ; C. S. Bruce, D. Hardisty, Miss I Harris and J. A. Leathley, University of Leeds.

Common Names of British Insect Pests

IN 1944 the Conference of Advisory Entomologist and the Pests and Diseases Committee of the Associ tion of Applied Biologists set up a joint sub-committe to prepare a list of common names of the insect an related pests of garden plants, domestic animal stored products and timber as they occur in Britai The first part, dealing with slugs and snails, eelworm beetles, hymenopterous insects and flies, was pul lished in 1947. The second part, dealing with lic thrips, plant bugs, aphids, and scale insect Lepidoptera, fleas, mites and ticks, has recentl appeared. Both parts consist of alphabetical lists o the accepted British common names (often with th American equivalents) and the corresponding scientifi names ; and alphabetical lists of the scientific name (under genera) and the recommended common name These lists will be of great value to all applie entomologists in Great Britain in enabling them t secure some degree of uniformity in the names o their pests. Not all the names will have equall ready acceptance by everyone. It is interesting t find the editor admitting quite frankly that "by th very nature of the International Rules governin Zoological Nomenclature the scientific names mus constantly be subject to revision". It is intended t publish revised lists from time to time. Copies o the list can be obtained from Miss Barbara M. Stokes Entomology Department, Rothamsted Experimenta Station, Harpenden, Herts (Part 1, 2*s*. ; Part 2, 3*s*.)

Scientific Papers Published in the Middle East

LIST No. 6 (December 1950) of "Scientific Paper published in the Middle East", issued by the Unesc Middle East Science Co-operation Office, Cairo, cover papers published in Cyprus, Egypt, Iran, Iraq, Israel Lebanon, Pakistan, Sudan, Syria and Turkey, an received by the Office between March 1 and Novembe 1, 1950. Publications from Pakistan are included fo the first time, and the issue includes more tha thirteen hundred titles, arranged under the Universa Decimal Classification. There is also a list of period icals included, arranged by country of origin, and list of abbreviations used. Roughly two-fifths of th entries fall under the medical sciences, one fifth i engineering and various industries, and one fifth i agriculture, forestry or stockbreeding. An autho index covering the first six lists published by th Office at Cairo (pp. 27) has also been issued. Wit regard to Arabic names, only the last (according t Egyptian usage) has been retained as surname, and whenever possible, only one spelling has been selecte in the transliteration of Arabic sounds.

British Interplanetary Society

THE annual report of the British Interplanetar Society for 1951 (pp. 18 ; from the Society, 15 Friary Road, London, S.E.15 ; 1951) shows remarkable enthusiasm among its fellows an members, and also a keen public interest, judgin from the number of lectures delivered during the 1950–51 session. Although the Society has bee in existence for only six years, it appears that it expansion has been such that a full-time clerica orker is necessary. Membership is open to all, no chnical or other qualification being required, and w numbers about fifteen hundred—a remarkable hievement in six years. Fellowship is restricted o those who possess some relevant scientific, technical or professional qualifications", and its requireents are specified under seven categories which ngo from a degree, from a recognized university, mathematics, engineering or medicine, to "conderable contributions to the development of tronautics". A recent issue of the *Journal* of the ciety (11, No. 1, January 1952) contains a number articles, including one by Oscar Schachter with the tle. "Legal Aspects of Space Travel". It is suggested that there will be a demand that the use of ter space for military purposes should be outlawed, d Mr. Schachter seriously states that it does not em to be too early for governments to give conderation to this aspect of the problem.

useum of Applied Science of Victoria : Annual Report for 1950–51

THE annual report for 1950-51 of the Museum of pplied Science, Victoria (pp. 13 ; from the Museum, elbourne, 1952), includes some interesting remarks ncerning policy. When the Museum was estabhed in 1870, its main functions were twofold, to ve guidance to artisans and to accumulate a comete record of technological achievement in the form exhibits. The former function has long since ssed to organized technical education, and to some tent the latter has collapsed under its own weight. he past half-century has been one of unparalleled ientific achievement, with the consequence that ience museums of moderate means have experienced fficulties in keeping abreast with modern knowledge. ut the Museum staff are viewing their responsilities in a new perspective and now tend to conntrate their attention on the presentation not of an ncritical accumulation of scientific material, but on lected facets that give the layman an understanding the impact of science on society, preserving a reful balance between the historical and the modern, d exploiting new ideas of display.

ritish Internal Combustion Engine Research Association : Elections

AT the recent annual general meeting of the British nternal Combustion Engine Research Association, e following elections were made : *President*, Visunt Falmouth ; *Vice-Presidents*, Air Commodore . R. Banks, Dr. S. F. Dorey (chief engineer surveyor, loyd's Register of Shipping), Sir Lynden Macassey ndependent chairman of the British Internal Comustion Engine Manufacturers' Association), Vicedmiral (E) the Hon. Sir Denis Maxwell (engineer-iniief of the Fleet), Major-General H. E. Pyman lirector-general, Fighting Vehicles Division, Ministry Supply) and Lieutenant-General Sir Frederick Wrisrg. At the same meeting, a new and smaller reprentative Council was elected as follows : Mr. H. N. G. llen (*chairman*), Mr. Miles Beevor, Mr. G. W. Bone, r. F. A. Perkins, Mr. C. G. Tangye and Mr. A. C. eates, with Mr. C. A. Spencer as the representative the Department of Scientific and Industrial esearch.

nternational Geographical Congress

THE Seventeenth International Geographical Coness, held at Washington, D.C., during August 7–15, tracted a record number of nearly 1,500 registrations, of whom 1,200 were actually present. More than five hundred delegates came from the forty-one countries adhering to the International Geographical Union. At the concluding General Assembly, Prof. L. Dudley Stamp (Great Britain) was installed as president in succession to Prof. G. B. Cressey (United States), who becomes vice-president, and Mr. G. H. T. Kimble (American Geographical Society of New York) was re-elected secretary-treasurer. The remaining six vice-presidents to be elected were His Excellency Dr. Hans W:son Ahlman (Sweden), Prof. Hans Boesch (Switzerland), Prof. George Kuriyan (India), Prof. Orlando Ribiero (Portugal), Prof. Max Sorre (France) and Prof. H. O'R. Sternberg (Brazil). By a large majority the Assembly accepted the invitation of Brazil to hold the eighteenth Congress in Rio de Janeiro in 1956. Prior to the Washington meeting, many of the delegates had participated in the centenary celebrations of the American Geographical Society, at which J. M. Wordie, president of the Royal Geographical Society, received the Daly Gold Medal.

Chemistry of Cement : Symposium in London

THE Cement and Concrete Association, in conjunction with the Building Research Station, is organizing an international symposium on the chemistry of cement, to be held in the Royal Institution, Albemarle Street, London, W.1, on September 15, and in the Royal Society of Arts, John Adam Street, Adelphi, London, W.C.2, during September 16–19. The symposium will be under the presidency of Sir Ben Lockspeiser, secretary of the Department of Scientific and Industrial Research, with Sir Francis Meynell, director of the Cement and Concrete Association, as vice-president. The five sessions, to be held on successive days, will be devoted respectively to the following topics : introductory addresses (followed by two papers and discussion) ; the constitution of Portland cement ; the setting and hardening of Portland cement ; special cements ; and applications of research. The sessions will be mainly devoted to the reading of papers and subsequent discussion. A number of excursions have been arranged (with one on September 14 and several on September 20) and these include visits to the Building Research Station and to the Research Station of the Cement and Concrete Association. Attendance at the symposium is by invitation only. Further information can be obtained from the organizing secretary, Philip Gooding, Cement and Concrete Association, 52 Grosvenor Gardens, London, S.W.1.

French Metallurgical Society : Autumn Meeting in Paris

THE Société Française de Métallurgie will hold its 'Journées Métallurgiques d'Automne' during October 20–25 at the Maison de la Chimie, 28 bis rue St. Dominique, Paris 7^e. The two main subjects to be discussed will be : faults and fractures observed in metals during service ; and methods of effecting economies in metals in short supply, including the rational use of alloys and the substitution of different varieties or qualities of alloys or methods of fabrication to ensure the best possible use of scarce elements. A few communications on other subjects of particular interest will be allowed at some of the sessions. The programme will include communications by metallurgists from many European countries and from the

United States. A number of visits, including one to the new laboratories of the Institut de Recherches de la Sidérurgie, at Saint-Germain-en-Laye, will also be arranged. Other visits and a banquet will be held during the week. Those desirous of attending the meeting should write to the secretary of the Society at 25 rue de Clichy, Paris 9e, from whom all further information can be obtained.

Colonial Service : Recent Appointments

THE following appointments have recently been made in the Colonial Service: D. R. N. Brown (agricultural officer, Uganda) and D. F. Stewart (senior agricultural officer, Uganda), assistant directors of agriculture (field), Uganda; J. C. K. Marshall and F. S. Walker (senior assistant conservators of forests, Federation of Malaya), conservators of forests, Federation of Malaya; W. H. Reeve (chief geologist, Northern Rhodesia), director of the Geological Survey, Northern Rhodesia; Dr. J. A. Simpson (biochemist, Federation of Malaya), chief biochemist, Federation of Malaya; R. A. Robinson, plant pathologist, Kenya; R. J. Isaacs, livestock officer, Nyasaland; I. A. D. MacKenzie, assistant conservator of forests, Nigeria; J. G. McGregor and B. Woodacre, assistant meteorologists, West African Meteorological Service, Nigeria.

The Night Sky in September

FULL moon occurs on Sept. 4d. 03h. 19m., U.T., and new moon on Sept. 19d. 07h. 22m. The following conjunctions with the moon take place: Sept. 9d. 03h., Jupiter 7° S.; Sept. 21d. 02h., Saturn 7° N.; Sept. 21d. 14h., Venus 6° N.; Sept. 25d. 18h., Mars 3° N. In addition to these conjunctions with the moon, Venus is in conjunction with Saturn on Sept. 15d. 23h., Venus being 1·6° S. Mercury is a morning star, rising at 3h. 55m. and 4h. 50m. at the beginning and middle of the month, respectively, in the latter case about fifty minutes before sunrise, and after this it becomes more difficult to observe. On Sept. 6d. 20h. it is in conjunction with Regulus, Mercury being 0·9° N. Venus, an evening star, sets at 19h. 20m., 18h. 55m. and 18h. 25m. on September 1, 15 and 30, respectively. Its stellar magnitude is − 3·3, and more than 90 per cent of its illuminated disk is visible. Mars, an evening star, sets at 21h. 10m., 20h. 45m. and 20h. 25m. at the beginning, middle and end of the month, respectively, its stellar magnitude varying from 0·4 to 0·6. At the beginning of September the planet is a little south of β Scorpii, and about a week later it is north of Antares, magnitude 1, with which it could be confused owing to its ruddy colour; but Mars is a little brighter than the star. Jupiter is visible throughout the night, its times of rising being 21h. 05m., 20h. 10m. and 19h. 10m. on September 1, 15 and 30, respectively, stellar magnitude − 2·2. Saturn, an evening star, is too close to the sun for favourable observation, setting less than an hour after the sun during the greater portion of the month. No occultations of stars worth observing occur at Greenwich during September. Vernal equinox occurs on Sept. 23d. 02h.

Announcements

PROF. F. BLAKEMORE, professor of veterinary medicine in the University of Bristol, has been appointed a member of the Agricultural Improvement Council for England and Wales in succession to Sir Thomas Dalling, who is taking up a post in the United Nations Food and Agriculture Organization.

DR. G. P. CONTRACTOR, acting director of tl National Metallurgical Laboratory, Tatanagar, Indi has been appointed to the additional post of ex-offic director of inspection (metallurgy), Tatanagar, in th Directorate General of Supplies and Disposals, of tl Ministry of Works, Housing and Supply, India.

THE Alvarenga Prize for 1952 of the College Physicians of Philadelphia has been awarded to D Norbert Wiener, professor of mathematics in th Massachusetts Institute of Technology, for his co tribution to the field of cybernetics. The Prize is a annual award and was established in 1883 by th will of Pedro Francisco DaCosta Alvarenga, of Lisbo Portugal, an associate fellow of the College.

THE annual exhibition of the Amateur Entom logists' Society will be held at Buckingham Ga Central Schools, Wilfred Street, London, S.W.1, o September 27, starting at 2 p.m. The Society we comes anyone interested in entomology. Furth particulars can be obtained from K. H. Bobe, 1 Hengist Avenue, London, S.E.12.

THE fourth exhibition and symposium of th Electrical and Electronics Section of the Scientifi Instrument Manufacturers' Association will be hel in the Examination Hall, 8–11 Queen Squar London, W.C.1, during September 2–5. Furthe information can be obtained from the secretar A. G. Peacock, Scientific Instrument Manufacturer Association, 20 Queen Anne Street, London, W.1.

THE firm of W. Watson and Sons, Ltd., is holdin an exhibition on "The Microscope in Industry an Research" in the Lecture Room of the New Horti cultural Hall, Westminster, London, S.W.1, durin September 15–19 (September 15, 2–6 p.m.; Septem ber 16–18, 10 a.m.–6 p.m.; and September 19 10 a.m.–4 p.m.). A brochure referring to the exhibitio can be obtained from W. Watson and Sons, Ltd. 313 High Holborn, London, W.C.1.

THE Third International Congress on Astronautic will be held in Stuttgart during September 1–6 Further information can be obtained from th Gesellschaft für Weltraumforschung, Greutterstrass 18, Stuttgart-Weilimdorf.

A SYMPOSIUM on "The Applications of Photograph to Research at the University" will be held by th Scientific and Technical Group of the Royal Photographic Society on October 4 in the Zoology Department, Downing Street, Cambridge. The wide variety of uses made of photographic techniques in th research work carried out in the University of Cambridge will be considered, including the topics o high-speed photography, electron microscopy, colou photography and flash cinematography. Brief paper will be read, with time for discussion after each Further details can be obtained from the honorar secretary, Mr. D. H. O. John, c/o May and Baker Ltd., Dagenham, Essex.

IN the obituary appreciation of Prof. H. Kramer published in *Nature* of July 19, we inserted th description "professor of theoretical physics in the Technical University of Delft". Prof. L. Rosenfeld writes: "from 1936 until his death, Kramers's main position was that of professor of theoretical physics in the University of Leyden. It is true that he also held concurrently a so-called 'special professorship' at the Technical University of Delft, but this was a secondary position, involving only very slight duties."

MEDIUM-ENERGY NUCLEAR PHYSICS

CONFERENCE IN PITTSBURGH

THE University of Pittsburgh sponsored a conference on medium-energy nuclear physics which et in Pittsburgh during June 5–7. There were five essions at which invited papers were given, followed y informal discussion. The first paper was that by . Scharff-Goldhaber (Brookhaven National Labor- tory) under the title "Excited States of Even–Even uclei", in which she discussed the energy-level parations and the spins of the excited states of these iclei. Regularities in these quantities are found hen the nucleus is thought of in terms of the shell odel, where most nuclear properties are ascribed to e nucleons outside the 'closed shells'. An instructive odel showing the excitation energy of the first xcited states of nuclei, based on the General Electric otope chart, was also shown. This paper was llowed by one by R. F. Christy (California Institute Technology) with the title "Selection Rules and oupling Rules in Light Nuclear Reactions". Dr. hristy proposed that there may be parameters scriptive of nuclei which are almost good quantum umbers for light nuclear reactions. Among these are e isotopic spin T and the partition numbers (p, p', ") of Wigner. Finally, he mentioned certain reactions hich are consistent with Russell–Saunders coupling n nuclei and not with j–j coupling.

At the second session of the conference papers were ead by M. E. Rose (Oak Ridge National Labor- tory), S. Ridgway (Princeton University) and S. T. utler (Cornell University). Dr. Rose, speaking on e "Angular Correlation of Nuclear Radiations", id that he was particularly interested in the effect n angular correlations of external perturbations cting on the nucleus. These lead to quenching of he angular correlation. He also described the rinciples which enable one to deduce the value of he magnetic moment of a nucleus in the state etween the emission of two successive gamma-rays. r. Ridgway reported on studies of the angular orrelation between beta-rays and subsequent gamma-ays. This correlation has been investigated eoretically and depends on the Coulomb correction ctor in the spectrum. Experiments have been done n several nuclei, including arsenic-76 and antimony-24. The third speaker, Dr. Butler, outlined the hysical principles underlying his calculations of the ngular distributions resulting from stripping re-ctions. A stripping reaction is one in which a euteron is incident on a nucleus, the nucleus bsorbing either the proton or the neutron from the euteron and making a direct transition to its final tate, the other constituent of the deuteron going ast. The energy and angular distribution of the nabsorbed particle give information about the state f the absorbed particle in the final nucleus. Dr. Butler then showed how the effect of the Coulomb nteraction between the incident proton and the ucleus could be taken into account, both when the eutron and when the proton is absorbed.

H. W. Fulbright (University of Rochester), H. J. Richards (University of Wisconsin) and H. E. Gove Massachusetts Institute of Technology) were the peakers for the third session of the conference. Discussing "Observations of Angular Distributions in ome (d,p) and (d,n) Reactions", Dr. Fulbright said hat the study of the beta-decay of certain elements, notably carbon-14, does not lead to complete understanding of the states of the nuclei involved. The theory of Butler, described above, provides an alternative approach to this problem. If the measured angular distribution from a stripping reaction fits one of Butler's theoretical curves, the angular momentum state of the absorbed particle can be inferred. Good enough agreement with such curves has been found to allow the inference, for example, that carbon-14 and nitrogen-14 ground-states have even parity. Dr. Richards, in the next paper, gave a detailed account of the assignments of spins and parities to the energy-levels of boron-10. He showed how the information from many kinds of experiments can be fitted together to yield a consistent assignment, and indicated the sources of some ambiguities. Dr. Gove then presented some results obtained with the cyclotron at the Massachusetts Institute of Technology. These included some energy-levels obtained by the inelastic scattering of protons and by stripping reactions. The angular distributions from stripping reactions were compared with those predicted by Butler and by Tobocman and Friedman. There appears to be a systematic angular displacement towards larger angles than those predicted.

For the fourth session of the conference there were three prepared contributions by, respectively, D. R. Inglis (Argonne National Laboratory), and by A. de-Shalit and E. P. Wigner (both of Princeton University). Dr. Inglis spoke on the subject "Departures from Nuclear Models in the p-Shell". He started by discussing a situation in atomic spectra where two different perturbations, the spin-orbit coupling and exchange effects, cause splitting of the energy-levels. In nuclei this spin-orbit coupling leads to the shell model of the nucleus, while the exchange splitting can be described by the Russell–Saunders coupling. Dr. Inglis then showed how complicated things can become in the intermediate region and discussed the light nuclei in the light of this 'intermediate coupling'. Dr. de-Shalit then pointed out some regularities in the deviations of magnetic moments from the Schmidt lines, in particular the fact that a nucleus with one odd proton has a moment farther from the Schmidt line than the corresponding nucleus with an odd neutron. He proposed an explanation of this in terms of j–j coupling. This paper was followed by that of Prof. Wigner, who started by reminding his audience of several well-known "queer facts" about nuclei, consisting of accurate numerical sequences or equalities. He then proceeded to discuss the possibility that spin-orbit coupling nuclear has as its origin the operation of a tensor force between pairs of nucleons in nucleus. Dr. Feingold has made calculations which give, in light nuclei at least, qualitative agreement between theoretical and experimental values of the magnetic moment and the quadrupole moment. The admixtures of states produced by the tensor force are small, so that Russell–Saunders coupling holds to a good approximation.

The three papers given at the concluding session of the conference were by W. W. Buechner (Massachusetts Institute of Technology), R. S. Bender (University of Pittsburgh) and Katherine Way (National Bureau of Standards). Dr. Buechner described the apparatus used for both low-energy and high-energy precision determinations of energy-levels, using for the latter the new Van de Graaff generator at the Massachusetts Institute. Results have been obtained for a variety of elements, in many places checking with those obtained elsewhere at low energy, and adding many new ones at high energy. Dr. Bender described the unique high-resolution beam analysing system used with the University of Pittsburgh cyclotron. He then summarized the results so far obtained by its use. These consist of energy-levels obtained from (pp'), (p,α) reactions; many old levels have been found, some with new precision, and many new highly excited levels have been located. Finally, Dr. Way reported a new set of values for the binding energies of the nuclei above lead, and also in the region around neutron number 50 and atomic number 50. These were obtained by considering closed cycles involving alpha-decay and beta-decay. On the basis of the existing experimental data, differences in binding energies at both the neutron and proton 'magic' numbers showed up clearly.

Discussion leaders for the sessions included Dr. Maria Mayer (Argonne National Laboratory), Dr. Maurice Goldhaber (Brookhaven National Laboratory), Dr. S. T. Butler (Cornell), Dr. G. C. Wick (Carnegie Institute of Technology), and Dr. T. Lauritsen (California Institute of Technology).

PHILIP M. STEHLE

ISOTOPES IN MEDICINE

THE application of isotopes in medicine is a subject which shows signs of dangerous over-popularization, with the consequent unjustified simplifications of the problem. A recent publication, entitled "Isotopes in Medicine"*, must therefore be very welcome since this series of articles, a number of them reviews, by acknowledged authorities in their respective fields demonstrates clearly the limitations as well as the possibilities of the clinical and biochemical applications of isotopes. The title "Isotopes in Medicine" is misleading, since only a few of the direct applications of isotopes in medicine are discussed and a number of papers are devoted to reviews of biochemical investigations which are unlikely to exert much influence on clinical medicine for some time. This, however, is not meant as a criticism of the standard of the material, which is high, and the editor is to be congratulated on his choice.

Isotopes represent an important new weapon in the armoury of the clinician and the biochemist; but it is clear that they rarely provide a short cut to the solution of a given problem, and their use demands not only considerable technical resources but, above all, a wide knowledge and experience of the particular field in which they are to be applied. The use of radioactive isotopes in radiotherapy can only be based on a wide experience of orthodox methods of radiation therapy, as is clear from the contribution to this volume by Ralston Paterson and his colleagues. In biochemical research the use of isotopes has in a number of fields raised rather than solved problems, and advances in the applications of isotopes will, to a very large extent, depend on advances in general biochemical theory and technique.

The basic problem in the clinical application of radioactive isotopes is that of obtaining adequate localization of the isotope within the required tissue. A degree of localization is required for both ther peutic and diagnostic applications, but in therapeut work a much higher degree of localization is neede in order that the healthy tissues of the body shou not suffer too great damage. The concentration iodine by the thyroid has been made the basis many diagnostic and therapeutic studies, which a well reviewed in this volume; but it must admitted that the popularity of thyroid studies wi iodine is largely due to the fact that iodine alone all the elements will achieve by metabolic process a high degree of localization within the body.

Increasing use is being made in radiotherapy radioactive isotopes in the form of discrete sourc used either externally or within the body. No pape on this aspect of the subject are included, which perhaps reasonable since the problems are basical technical ones, and the clinical applications follo along the lines of treatment with X-rays and wi radium sources. Other methods of providing localized irradiation of the required tissues are bei developed, and two of the recent techniques are di cussed. A description is given of the treatment malignant bladder conditions by a radioacti solution enclosed in a rubber balloon in the bladde and of irradiation of the pleural and peritone cavities by the injection into these cavities of radi active gold in colloidal form.

The diagnostic application of isotopes involves a large extent radiation measurements made exter ally to the patient and thus must depend basical on instrumentation. An application is described scintillation counting in an attempt to diagnose bra tumours following administration to the patient fluorescein labelled with iodine-131. So far, in Gre Britain, the results with this technique have not be very promising.

One of the most simple and direct applications radioactive isotopes in diagnosis lies in the study blood flow. Here a measure is required only of t rate of transport of radioactive material injected in the blood, and valuable clinical applications ha been found for this technique, described in seve papers of this volume.

On the technical side the volume contains a numb of extremely useful articles, in particular that L. H. Gray entitled "General Principles of Ass and Standardisation of Radioactive Isotopes". report is also given by members of the staff of t Radiochemical Centre, Amersham, on the ava ability of labelled compounds, with details of t methods of synthesis of a number of compoun labelled with carbon-14.

NATIONAL INSTITUTE OF AGRICULTURAL ENGINEERING

OPEN DAYS

THE National Institute of Agricultural Engine ing, at Wrest Park, Silsoe, Beds, held op days during July 22–24, when exhibits were stag to illustrate to visitors the work of the Institu The exhibits did not cover the whole programme the work in hand at Wrest Park (which is report more fully in the recent report for 1949–51 [1]); b even so, they were quite comprehensive a representative of many aspects of the activities the departments.

Noticeable features were the use made of instrumentation, comprising standard, modified or specially esigned apparatus for use not only under laboratory onditions but also in the field ; of techniques devised o meet the great variety of investigations underaken ; and of the experience and facilities of the nstitute for developing machinery and equipment rimarily for use by other research institutes. Examples of the last were the fertilizer placement machines shown by the Mechanical Engineering Department to meet the needs of research workers t Rothamsted Experimental Station and the Macaulay Institute for Soil Research ; the combine arvester, using a new principle of threshing, for arvesting crops grown on plots ; an elevator-oader for handling potatoes into covered storage, tted with a sprout depressant dust-feed, for he Potato Storage Investigation Team of the Agricultural Research Council ; and a press for the xtraction of protein from macerated leaf which has een developed in association with Rothamsted and he Grassland Research Station.

The Mechanical Engineering Department is reponsible for carrying out official tests of tractors nd accessories, grain cleaners and driers, and grass riers. A full-scale test of the last was demonstrated, nd included a specially designed mobile laboratory. A good deal of equipment has been developed for ractor testing, and that exhibited included a hydraulic loading car, drawbar dynamometers, a mobile belt-dynamometer and a power take-off dynamometer ; a mobile trailer weighbridge used for grass-drier tests was also shown.

Research into the design and operation of tractors is proceeding with the help of the foregoing equipment, and a single-wheel tester which has been under development is now completed and will also be used or tractor testing. Research is chiefly concerned with the factors affecting the efficiencies of the engine, ransmission and driving wheels ; attention is also being given to the possibilities of using hydrostatic ransmission, and an experimental motor built into he driving wheel of a tractor was on view.

Tests of agricultural machinery other than that already mentioned are the concern of the Agricultural Testing Department, and examples of the methods and equipment used were to be seen. These included a ploughing-depth recorder ; portable weighers for wheels, sacks, bales, etc. ; apparatus for collecting he complete contents of a potato ridge *in situ* and or sorting and grading them, for the measurement of the power requirements of machines and the dirt and top tare of sugar beet, and for the calibration and testing of seed drills and fertilizer distributors ; and the method used for the detection of mechanical damage to potatoes. The work of this Department also includes investigations into the spring mechanization of sugar beet—a Dixie down-the-row thinner was at work—and the loss of sugar and dirt in field lamps of sugar beet.

The activities of the Horticultural Engineering Department cover a wide field ; those displayed elated to overhead irrigation, spraying, frost prevention, glasshouse heating and ventilation, tractor teering, the washing of vegetables and the harvesting of onions. Modern techniques such as those employing electronic apparatus have been brought into use ; both irrigation and spraying for plant protection call or the production, control and distribution of roplets, and the assessment of the resulting patterns. A high-speed camera is used for the study of spray formation by nozzles of different patterns, and the apparatus and photographs were shown ; a dye is used in many of the sprays, and spray patterns were on view—the dye serves both for visual inspection and for colorimetric and gravimetric estimation. In co-operation with the Research Branch of the Post Office Engineering Department, photoelectric scanning apparatus and electronic counters have been adapted for studying spray patterns and providing data as to the number and sizes of the droplets deposited ; the apparatus was demonstrated in use[4].

Methods of frost prevention include fans and water sprays, and equipment and results were to be seen.

The apparatus used in the study of glasshouse heating and ventilation was shown, and included instruments for measuring and recording soil moisture, soil and air temperatures, air flow, carbon dioxide concentration, solar radiation and heat losses ; the results of this work to date and also those of steam sterilization of soil were displayed.

Research work has been commenced into the problems arising from the design or adaptation of a tractor to meet the exacting requirements of market garden crops. Steering is receiving attention as a primary consideration, and a steering-deviation recorder and a speed and torque recorder were open to inspection. Adaptation has involved reversing the normal driving position and transmission of a tractor and mounting the implements ahead of the front driving-wheels of the reversed tractor in full view of the driver.

Research and development on ploughs and other tillage implements and on potato harvesters have revealed the need for more information about soil conditions, and a section of the department concerned has been formed which is devoted to soil physics ; it is now known as the Soil Department. Known methods and new ones have been devised for obtaining, especially in the field, the data required. A soil penetrometer and torsion shear box were shown, and a demonstration was staged to illustrate the effect of compaction of the soil by tractor wheels.

Strain-gauge equipment in conjunction with a mobile laboratory was exhibited, by which the forces acting on a plough, on a tine or on the linkage of direct-mounted implements are recorded.

The development of a satisfactory potato-harvester has engaged the attention of the Institute for a number of years ; the experience gained has been incorporated in the latest development, which takes the form of two separate units—a digging unit on a rear-mounted toolbar and employing a disk share for digging, and a rotating spider for separation ; the crop can be left on the ground or an elevator can be fitted to deliver into a trailer, which can be fitted with a detachable picking conveyer. The separation of functions makes the arrangement suitable for the small grower.

The drying, handling and storage of cereal crops are the principal interests of the Grain Department ; investigations have been carried out to improve the efficiencies of the installations developed—many of which are now in use on farms—and to extend their application, for example, to green crops and overseas products. Experimental plant of different types was on exhibition, including ventilated silos of concrete and fabric, a grain elevator, grain cleaner, platform sack drier used also for green crops, and special apparatus for measuring air flow, temperature, humidity, pressure drop, moisture content, etc.

Field surveys are carried out by the Field Investigation Department, and an independent survey of tractor utilization is in hand. Potato planting and harvesting, sugar beet and grain harvesting, and hay-making are under investigation. Present farming practice is studied, and planned trials, so far as practicable under controlled conditions, are undertaken. Results, methods and equipment were to be seen. A portable windrow weigher has been devised; but much of the apparatus used is that already mentioned in connexion with testing.

The main laboratories, forming the Instrumentation Department, are at the service of all departments. There special investigations are carried out, for example, on the specific heat of soils, ploughshare wear and precision drilling, besides routine calibration and analyses. Moisture content determinations are a prominent feature for which standard methods are not always suitable, and special apparatus has to be devised to cope with a wide variety of products—for example, apparatus was in use dealing with grass, with coffee beans and with tomatoes.

Considerable use is made of photography, including ciné-films; two ciné-films with tape-recorded commentaries were shown in the Conference Room each day; the Library, which handles not only books, bulletins and periodicals but also manufacturers' catalogues and Institute photographs and slides, was open to visitors.

SPORTS TURF RESEARCH INSTITUTE

MACHINERY EXHIBITION AND OPEN DAY AT THE ST. IVES RESEARCH STATION

THE combined machinery exhibition and open day of the Sports Turf Research Institute, held during July 15–16 at the St. Ives Research Station, Bingley, proved to be a very successful event of great interest to all users of sports turf. Manufacturers combined to put on show a wide variety of implements used in turf production and maintenance, and to many people it was a revelation to see the amount and variety of machinery called for to uphold modern turf standards in face of the increasingly heavy demands being made on playing areas. Mowing machines of very many types naturally were much in evidence; but there were also, among other things, tractors, fertilizer distributors, line-marking machines, compost shredders, turf-cutting implements, watering tackle, weed sprayers of all sizes and a variety of implements for piercing turf in order to relieve soil compression and facilitate easy ingress of air and water. A wide range of hand- and power-drawn machines was demonstrated. A recent development has been the use of the three-point hydraulic linkage of tractors for operating spiking equipment, while a new power-driven spiker, shown for the first time, roused much interest.

The variety of sprayers on view may be taken as a measure of the interest taken in weed control. On the experimental ground, where a number of current trials were demonstrated, the subject of weed control
also received attention. Weedkillers based on 2 : 4 I
(2 : 4-dichloro-phenoxyacetic acid) and M.C.P.A
(2-methyl-4-chloro-phenoxyacetic acid) have prove
a great boon, but some weeds have proved somewha
resistant and work on these is proceeding. On sho
were experimental plots treated with 2 : 4 : 5
(2 : 4 : 5 trichloracetic acid) at various rates wit
and without admixture with 2 : 4 D and M.C.P.
Results obtained against clover were very promisin
indeed, but yarrow control did not appear so goo
There were also trials of exfoliated vermiculite f
turf establishment and maintenance and on the u
of bitumen for toughening turf to withstand hea
wear. Further field trials on view included a numb
on grass-seed mixtures for various purposes a
others on fertilizer treatment. Among the latter mu
be mentioned a series which must be about the olde
of its type existing, since in it individual plots ha
received their own particular kind of fertilizer trea
ment for a period of more than twenty years. T
effects of these treatments on botanical compositio
pest and disease invasion, drought resistance and t
like were easy to see.

Much interest was displayed by visitors in t
laboratories which were open to them. The increasi
demand for scientific advice is well shown here, sin
only last year a new chemistry laboratory had to
fitted out to cope with the increasing demand f
analytical work, while this year visitors were able
see for the first time the new Biology Departme
Though its laboratory space is somewhat limited, t
Department has an ambitious programme and
already making its presence felt.

This new Department undertakes routine exami
tions of diseased turf, the identification of turf plan
and turf pests; in addition, both short- and long-te
schemes of research, mainly in the realms of t
diseases, are being conducted. In Great Britain th
is not the great variety of turf diseases which may
found in, say, the North American continent,
there are definite problems in need of soluti
Improved methods of control of *Fusarium* pa
disease are being sought, and new fungicidal materi
are on test in the laboratory and in the field for t
purpose.

A study is being made of the biology of 'fa
rings' as a necessary preliminary to the devising
methods for their elimination. In the popu
literature on turf management much has b
written on the control of 'fairy rings'; but tr
with reported curative treatments seldom seem
have been conducted under adequately contro
conditions.

STANFORD RESEARCH INSTITU
CALIFORNIA

REPORT FOR 1951

IN an address, "Research and Industry—Part
in Progress", to the board of directors of
Stanford Research Institute, California, on
occasion of the fifth anniversary of the foundin
the Institute, Brigadier-General D. Sarnoff, chair
of the board of the Radio Corporation of Ame
said that the Institute is an outstanding exa
of the natural partnership between research
industry. That partnership, he believed, offers

greatest hope of solving the world's problems and industry's problems. It has always been true that the things men live with largely determine the ideas men live by, and the kind of economy and the kind of government we enjoy are determined mainly by the things industry produces and the use that is made of them. This is not a materialistic doctrine, he said, for there is also a spiritual factor which is possibly the most important, and research itself contributes to this: besides its creative and constructive value, its contribution to economic security and thus to peace, and its challenge to competition, research contributes such values as objectivity and the patient, persistent search for the truth to the partnership on which industrial progress depends. Business, for its part, should contribute understanding and encouragement, as well as finance, and General Sarnoff was emphatic that industry rather than government should bear a main responsibility for the finance of research: government control might destroy the very qualities that enable the research worker to make his most important contribution to society. The future of the Stanford Research Institute, he said, is bright because it recognizes the dependence of applied research on the new knowledge revealed through basic research and maintains a close relation with other research centres throughout the United States.

Some details of the growth of the Stanford Research Institute since 1947 and of its work during 1951 are given in the fifth annual report of the Institute*, which includes a quotation from General Sarnoff's address. Its full-time staff (scientific, technical, managerial and service) increased by 65 per cent during 1951 to 425, and, of the 214 projects on which the Institute was engaged, 184 were for commercial and government sponsors. Expenditure totalled 3·6 million dollars, compared with 1·99 million dollars in 1950, and close affiliation with Stanford University continued to be a vital factor in the development of the Institute.

In the Department of Chemistry, which with a staff of more than seventy-five now conducts research costing 1·2 million dollars annually, among the research projects mentioned in this report are those on the development of a method for the continuous large-scale separation of ionic substances, the efflorescence of latex paint films, the evaluation of ceramic materials, the oxidation of xylenes and the industrial uses of coconut oil derivatives. During the past four and a half years the Air Research Laboratories of the Institute have spent more than 2 million dollars in studying air-pollution problems in different parts of the United States. Besides developing much special equipment, the laboratories have intensified efforts to spread information on air-pollution dangers and their prevention. In the Applied Physics Department an ion-scattering analyser is under construction, and the radiation laboratory is attacking the primary objectives of developing processes using large quantities of radioactive material as a source of penetrating gamma-rays and providing all branches of the Institute with staff and facilities for experimental work with radioisotopes. The Division of Geophysics and Geology is continuing its programme on the development of the Poulter seismic method of surveying underground structures and is undertaking seismic exploration in Western Texas.

A staff of 125 is engaged on engineering research, and projects specifically mentioned in the report include studies on aircraft antenna theory and design, automatic assembly techniques for miniature electronic equipment, the development of the three-colour picture-tube system of television based on the Geer principle, and the response testing of pulse transformers. The Department of Industrial Economics, with a staff of sixty-five, has conducted a techno-economic survey of the hard-board industry; economic studies of Cuba and of a proposed crude-oil pipe-line from Edmonton, Alberta, to Vancouver, British Columbia; an investigation, for the United States Atomic Energy Commission, of the technological and economic questions involved in the industrial use of radioactive fission products; and a co-operative survey, with the South-west Research Institute, the Armour Research Foundation and the Battelle Memorial Institute, of fundamental and applied research activities in Western Germany. Biological research continued to expand; and in the biochemical field particular attention was given to problems of nutrition, toxicity, cancer and the effects of radiation, including studies of the effect of fluoride intake on the general health of cattle, the toxicity of chemicals used to prevent mould growth in citrus products, and the effects of X-radiation and radioactive isotopes on normal tissue and tumours.

The Institute continued to publish its "Chemical and Economics Handbook", and investigations sponsored by the Institute itself included a fundamental study of chemical reactions in aerosol systems, the design of a special still-head which eliminates the need for a separate receiver changer, a study of Goetz molecular filter membranes for the removal of pyrogens from aqueous media, the development of a fractionating column efficient at low pressures, the development and application of paper-chromatographic techniques, the reactions occurring between polymer molecules and the free radicals present during the formation of vinyl polymers, and a study of the applications in analytical chemistry of ion-exchange resins.

HOUSING IN THE U.S.S.R.

A BRIEF survey of housing development in the U.S.S.R. from 1917 until the present day by Dr. E. M. Chossudovsky (Housing and Town and Country Planning, Bull. 5, United Nations Publication) shows that the material difficulties with which the Government has had to deal have been formidable. The housing resources taken over by the Soviet authorities after the Revolution were both quantitatively inadequate and in appallingly poor condition. Very little new construction took place until the late 1920's, and it was not always possible to devote sufficient attention to repair work, so that the pre-revolutionary level of housing was restored less quickly than that of the other branches of the economy.

With the beginning of the era of the Five Year Plans (1928–29) the situation improved; altogether before the Second World War about 113 million square metres (approximately 1,216 million square feet) of urban living space had been constructed since the inception of the Soviet regime. Much was done by way of improving the quality of housing, developing and improving municipal services and providing communal buildings of all kinds.

Two hundred new cities were built between 1926 and 1939, in conformity with the changing character and distribution of the population and the development of the country's eastern areas. Yet, despite all this progress, it proved impossible to bridge the gap between population growth and housing; housing construction lagged behind the rate of industrialization, and the urban population increased at an exceptionally rapid rate. Further, much of the pre-revolutionary housing proved to be beyond repair and had to be scrapped, thus slowing down the net growth of the total housing fund.

The war-time destruction of housing amounting to some 30 per cent of the total amount of urban housing, and the extensive and frequently complete destruction of rural housing proved a serious setback. The over-fulfilment of the total urban housing programme of the post-war Five-Year Plan has, however, more than offset the tremendous losses and led to a far-reaching, even revolutionary, modernization of the building industry (especially in the application of express and even-flow methods of erecting houses), which should make it possible to step up housing construction in subsequent five-year plans to a marked extent. The pace of the country's house-building has been appreciably increased by the financial and material assistance accorded to individual house-building by the authorities.

In the present stringent housing situation, the Government has controlled the distribution of available housing resources, taking into consideration the priority claims of ex-servicemen, the dependants of war casualties and invalids, the partisans and their families. The relationship between work (type, quantity and quality) and the allocation of limited housing resources, already recognized before the War, has now been further strengthened; it is possible to ensure that the housing requirements of such key workers as the miners are promptly met. Special housing facilities also are provided to meet the needs of workers who settle in newly developed regions. Housing is thus regarded as one of the instruments for increasing the productivity of labour and building up permanent staffs in industry.

MUSEUMS ASSOCIATION

ANNUAL CONFERENCE IN OXFORD

THE fifty-eighth conference of the Museums Association was held at Oxford during July 21–25 under the presidency of Mr. S. D. Cleveland, director of the City Art Gallery, Manchester, and was attended by more than three hundred and fifty delegates from both national and provincial museums. This was the third occasion on which the Association has visited Oxford, the previous time being in 1919.

In his presidential address, on "The Inevitability of Museums", Mr. Cleveland stated that it is necessary to correct a prevailing misconception by which museums are regarded as educational institutions only. It is true, he said, that education must be an integral part of their work; but it should take its place with the other functions of collection, conservation, interpretation, research and service to the community.

Dr. H. J. Plenderleith, keeper of the Research Laboratory at the British Museum, in a paper on "Fakes and Forgeries", described his subject as a very human study in which the man of science can help the scholar. In fact, the intimate co-operation of these two is essential, and there must be complete sympathy with each other's aims and methods. He enumerated some of the physical and chemical methods used at the British Museum, and spoke of the difficulties encountered when it is necessary to form an opinion without even marking the object.

Sir Philip Hendy, director of the National Gallery, stressed that the primary function of museums and art galleries is to be a Temple of the Muses and that no secondary function should be allowed in any way to interfere. Museums are guardians of a high standard of quality. He spoke in favour of the production of good reproductions of first-class paintings and pleaded for a more liberal interpretation of the function of art galleries.

In a session of a rather more domestic nature, the story of museums in Oxford was told by the five directors concerned. In all the papers, and in the subsequent discussion, it was apparent that the pendulum is swinging once again with regard to the amount of material that should be displayed in museums. From showing everything, the general tendency a few years ago was to show almost nothing. Now a compromise has been made, and it is realized that the arrangement as seen in the windows of the departmental stores is not the ideal prototype for museum cases. The apathy of the University of Oxford towards its museums was commented upon by several speakers, and the hope expressed that one result of the conference on the part of the University would be an increased interest in the value of its great collections. The hope was also expressed that the City of Oxford would consider the establishment of a museum to illustrate its own history.

Speaking on "Changing Fashions in Museum Teaching", Mr. Peter Floud, of the Victoria and Albert Museum, London, emphasized the value of making use of the galleries in addition to the children's rooms which are now established in so many museums. There is a distinct danger that museum work may become simply an extra-mural function of the school. He also dealt with the three-dimensional didactic displays which produce indirect museum teaching, and illustrated his remarks with actual examples of exhibition work. Dr. C. H. V. Sutherland, of the Ashmolean Museum, Oxford, said that there is a real public interest in numismatics and that museums should make every effort to satisfy this. He agreed that there are few trained numismatists in Great Britain, and stated that a British association of the various numismatic societies would probably be formed in the near future. He hoped that the Museums Association would co-operate in this matter. Mr. J. W. Y. Higgs, of the Museum of English Life, Reading, described this new museum of English rural life and stated how, as a nation, England is deeply conscious of its rural history.

At the annual general meeting of the Association, held during the conference, a protest was made against the cuts in Treasury grants to national museums and art galleries. The Association decided to send to the Chancellor of the Exchequer a resolution deploring the cuts as "gravely endangering the safety of the national treasures and curtailing the educational, æsthetic and scientific facilities provided".

Dr. F. J. North, of the National Museum of Wales, Cardiff, was elected president for the Conference in 1953, which will be held in York during June 22–26.

IONIZING AND LUMINOUS EFFICIENCIES OF METEORS

By Dr. J. S. GREENHOW
and Dr. G. S. HAWKINS
drell Bank Experimental Station, University of Manchester

THE amount of ionization produced in the trail of a meteor of given visual brightness has been e subject of much discussion. Early workers[1] sumed that most of the kinetic energy of the eteor would be transferred to ionization ; but in a cent review Herlofson[2] considered that the available idence indicated that the fraction of the kinetic ergy converted to ionization was only about ·0001, and the fraction converted to visible radiation out 0·01. On this basis Herlofson estimated that e density of ionization produced by a meteor on e limit of naked-eye visibility (zenithal magnitude 6) would be 10^{10} electrons per centimetre path, d by a very bright meteor (zenithal magnitude 1) 10^{12} electrons per centimetre path. The preminary combined radio echo and visual observations ade by Prentice, Lovell and Banwell[3] in 1947 ggested that these estimates were approximately rrect. The theoretical estimates depend on a owledge of the transition probabilities in the llision of heavy ions, and in this respect data plicable to the conditions in meteor trails remain ry inexact. Thus, any new information on the easured electron densities in trails of meteors of own visual magnitude is of particular interest. ecent work on the mechanism by which radio waves e scattered from the ionized trails has led to much ore certain measurements of electron density. The rpose of the present communication is to discuss ese measurements, which indicate that the actual minous and ionizing efficiencies must be markedly ifferent from those assumed by Herlofson.

The original measurements of electron density ade by Prentice, Lovell and Banwell[3], and Lovell, anwell and Clegg[4], were based on the theory of attering developed by Lovell and Clegg[5]. This eory, which predicts that the amplitude of the echo proportional to the linear electron density α, sumes that the initial radius of a meteor trail is nall compared with the wave-length, the electron ensity being sufficiently low so that the electrons in ny cross-section scatter independently and in phase. nder these conditions, Herlofson[2] has shown that e echo duration to $1/e$ of the initial amplitude is dependent of the electron density, and is given by

$$T = \lambda^2/16\pi^2 D, \qquad (1)$$

here D is the diffusion coefficient for the ionized atter in the trail, and λ the wave-length. Although is theory seemed to account satisfactorily for many f the observations, the existence of echoes of long uration has provided a major difficulty[6]. This ifficulty has now been resolved, and recently[7,8] it as been shown that when the linear electron density ppreciably exceeds 10^{12} electrons per centimetre, the odel assumed by Lovell and Clegg breaks down, nd the cylinder in the meteor trail inside which the lectron density exceeds the critical value N_c may be onsidered to behave as a total reflector for radio aves. Under these conditions, the amplitude of the adio echo increases only as the fourth root of the electron line density, α, but the echo duration is now proportional to α, being given by[7]

$$T = \alpha/4\pi D N_c. \qquad (2)$$

It is the overdense trails of this type which give rise to the meteor echoes of long duration. Evidently equation (2) provides an accurate method of determining α, from measurements of the duration T, provided the diffusion coefficient D can be determined. In the present work, D has been determined from trails of low electron density which obey the Lovell–Clegg formula, and which decay exponentially according to (1). In order to obtain a satisfactory mean value of D, it is desirable to make measurements on a number of meteors ionizing in a narrow height-range, such as those in a homogeneous shower. The value of D may then be substituted in equation (2), so that the electron line densities in meteor trails which give rise to long-enduring echoes may be obtained directly from the echo durations, independently of the parameters of the apparatus.

The most extensive observations relating the magnitudes of visual meteors to the appearance of the corresponding radio echoes have been made by Millman and McKinley[9], operating on a wave-length of 9·1 m. From a mean of several hundred visual meteor–radio echo correlations obtained during the Perseid meteor shower, these workers found the relationship between the echo duration and apparent meteor magnitude shown in Fig. 1. The measurements of luminosity are in terms of apparent visual magnitudes, and these may be corrected to zenithal magnitudes by reducing the ranges of the observed meteor trails to 100 km. The mean range of Millman and McKinley's[10] radio echo and visual meteor correlations was 155 km., giving a ratio of apparent intensity to zenithal intensity, for an average meteor, of 1 : 2·4. This corresponds very nearly to one stellar magnitude, and this correction has therefore been adopted. The revised experimental curve relating zenithal magnitude to duration of radio echo is shown as a broken line in Fig. 1.

The conversion of these echo durations to electron densities has been made from equation (2) by using the value of D (4×10^4 cm.^{2}/sec.), determined from the measurements on short-duration Perseid echoes as described above[7]. The final relation between linear electron density and zenithal magnitude is given in Fig. 2 (line AB). Extrapolation of AB shows that a meteor of zenithal magnitude + 6 would produce

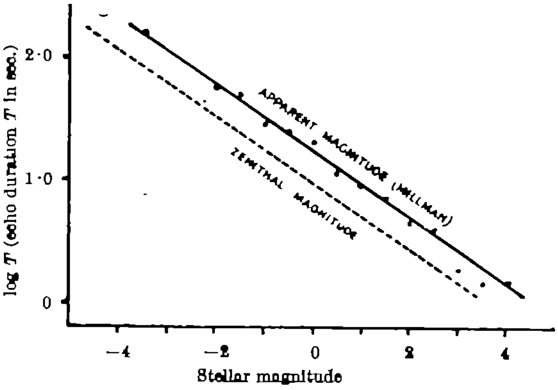

Fig 1. Relation between meteor magnitudes and radio echo duration on a wave-length of 9·1 m

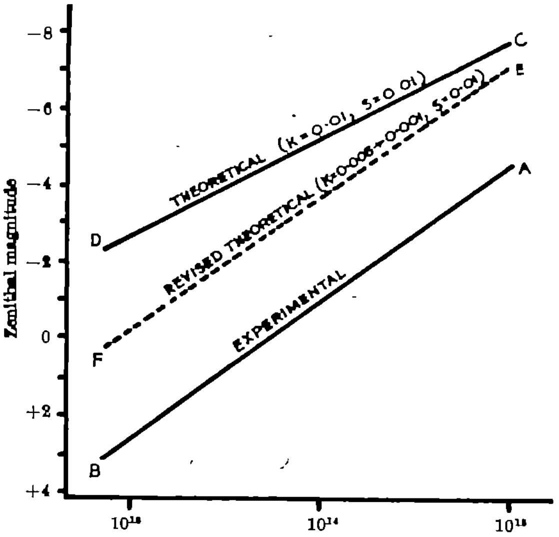

Fig. 2. Theoretical and experimental relations between the zenithal magnitudes and electron line densities of meteor trails

approximately 10^{12} electrons per centimetre path. This is one hundred times greater than Herlofson's estimate, and leads to a discrepancy of roughly 5 stellar magnitudes between the theoretical and experimental determinations of the electron line densities in meteor trails. The experimental points obtained by Prentice, Lovell and Banwell[8] for the relation between echo duration and magnitude during the 1947 Perseid shower agree with the relation found by Millman and McKinley in Fig. 1, when corrected for the difference in wave-length. The conversion to line density by these workers was made from the amplitude of the echo, on the assumption that the Lovell–Clegg formula applied to these trails. It is now evident that these trails were overdense, and that equation (2) should have been used for obtaining the electron density from the echo duration. The approximate agreement of their results with Herlofson's estimates was therefore fortuitous.

In view of the large disagreement between theory and experiment, it is of interest to search for any adjustments in the theory which could bring the results into agreement. The theoretical relationships between zenithal magnitude M and electron line density α, used by Herlofson, may be written as

$$M = 80{\cdot}4 - 2{\cdot}5\,(\log V^{3} + \log K/S + \log \alpha), \quad (3)$$

where V is the meteor velocity, S is the probability that an evaporated meteor atom will produce an electron by collision with air molecules, and K is the fraction of the kinetic energy of a meteor atom which is transformed into visible radiation. Originally, values of $S = K = 0{\cdot}01$ were adopted, producing the theoretical relation between zenith magnitude and electron line density given by CD in Fig. 2. The discrepancy between the theoretical and experimental relations in Fig. 2 suggests that the values assumed by Herlofson for S and K are incorrect.

A more exact theoretical estimate of the luminous efficiency for meteors with a velocity of 6×10^{6} cm./sec. has been made by Öpik, who obtained $K = 0{\cdot}001$ for faint visual meteors, and $K = 0{\cdot}005$ for very bright meteors (negative magnitudes). The luminous efficiency may also be estimated from th photographic observations by Whipple[11] and Jacchia[1 who obtained the following mean values from eleve bright Perseid meteors:

Velocity (V cm./sec.)	Deceleration (a cm./sec./sec.)	Zenithal magnitude (M)	Height (km.)
$6{\cdot}01 \times 10^{6}$	$8{\cdot}1 \times 10^{5}$	$-3{\cdot}0$	$92 \pm 1{\cdot}3$

For a meteor, the rate of loss of kinetic energ dE/dt is:

$$\frac{dE}{dt} = \frac{\tfrac{1}{2}\,dm}{dt}\,V^{2}\ \text{ergs/sec.} \qquad (4$$

The rate of loss of mass dm/dt may be obtained fro the deceleration of the meteor, a, and atmospher density ρ using Whipple's equation[11]:

$$\frac{dm}{dt} = 5 \times 10^{-18}\,\rho^{2}a^{-2}\,V^{7}\ \text{gm./sec.} \qquad (5$$

For the rate of radiation of luminous energy I, b an object of stellar magnitude M, Öpik[13] gives th expression:

$$2{\cdot}5 \log I = 24{\cdot}6 - M. \qquad (6$$

At a height of 92 km. the atmospheric density i approximately 6×10^{-9} gm./cm.^{3}, and when th observational data are inserted in equations (4), (and (6), the luminous efficiency $K = I \Big/ \frac{dE}{dt}$ is found t be 0·01. Because of the spread in the results, th value could be in error by a factor of 2, and it i therefore in fair agreement with the theoretic estimates of Öpik for bright meteors. The results c the photographic observations thus add weight t Öpik's estimates, and his values, when inserted i equation (2), produce the relation between magnitud and line density shown as EF in Fig. 2, and th discrepancy between the theoretical and experiment curves is reduced.

The probability of ionization, S, may be estimat from the direct correlation of radio echoes with visu meteors. From AB in Fig. 2 a Perseid meteor o magnitude $-3{\cdot}0$ produces $2{\cdot}4 \times 10^{11}$ electrons/se The rate of loss of mass for meteors of this brightne has already been determined from the photographi results, and, assuming the meteor to be composed o iron, corresponds to a release of 8×10^{11} atoms/sec This gives the probability of ionization as 0·3; bu the spread in the original data will give values lyin between 0·1 and 1·0. The remaining discrepanc between EF and AB is accounted for if $S = 0{\cdot}16$ which lies within the limits of this experimenta estimate.

In conclusion, it seems that the best values for th luminous efficiency of Perseid meteors are 0·005 fo bright meteors and 0·001 for faint meteors, and more reasonable value for the probability of ionizatio is approximately 0·2. Meteors therefore produce mor ionization than was originally estimated. Instead o the kinetic energy of a meteor being divided betwee heat, light and ionization, in the ratio $10^{4} : 10^{2} : 1$ the ratios are probably $10^{4} : 10^{2} : 10$ for brigh meteors, and $10^{4} : 10 : 10$ for faint meteors. The revised estimates imply that the visual magnitud corresponding to an echo of given characteristics i some 5 magnitudes fainter than that given b Herlofson. This means that the majority of radi echoes of short duration must arise from meteor which are below the limits of naked eye visibility, and conversely that all visible meteors must produce radio echoes of long duration—a well-known observational effect. [June 20.

PHOSPHORYLATION OF XYLOSE BY EXTRACTS OF *PSEUDOMONAS HYDROPHILA*

By Dr. ROLF M. HOCHSTER
and Dr. R. WADE WATSON

Division of Applied Biology, National Research Council, Ottawa, Canada

THE most generally accepted view of the pathway of xylose metabolism has been that of the splitting of the molecule into a C_3 and a C_2 portion[1]. The formation of xylonic acid from xylose by *Pseudomonas fluorescens* has been demonstrated by Lockwood and Nelson[2]. Lampen and Peterjohn[3] believe that xylose degradation occurs via a ribose phosphate, since only ribose-5-phosphate but not xylose-5-phosphate or arabinose-5-phosphate is metabolized by extracts of xylose-grown *Lactobacillus pentosus*.

That phosphorylation of xylose may take place in rat intestinal mucosa homogenates was recently suggested by the work of Hele[4]. No distinction was made, however, between the glucose- and the xylose-phosphorylating enzyme.

Evidence has now been obtained in these laboratories showing that xylose is phosphorylated at the expense of adenosine triphosphate by extracts of *Pseudomonas hydrophila* grown on a synthetic medium with xylose as the only source of carbon. In crude extracts, the initial rate of phosphorylation of xylose has been found to be much higher than that of glucose. Hexokinase activity has been successfully removed from the extract, leaving the xylose-phosphorylating enzyme intact in the final preparation. The latter enzyme has been shown to be specific for D-xylose among all the pentoses of known biological significance and will, therefore, be referred to as 'xylokinase'.

Culture conditions and preparation of cell-free extracts. *Pseudomonas hydrophila* (N.R.C. 492), originally isolated by Reed and Toner[5] from pike with 'red sore' disease, was grown on a synthetic medium composed of 20 gm. of D-xylose, 6 gm. diammonium hydrogen phosphate, 0·2 gm. potassium dihydrogen phosphate, and 0·25 gm. crystalline magnesium sulphate per litre of solution. Sugar and salts were sterilized separately and mixed aseptically before use. The *p*H of the medium after sterilization was 6·6, and this value dropped to 6·0 following a 24-hr. period of growth of the organism. The average yield of cells from 24-hr. shake cultures was 5·4 gm. per litre of culture medium.

The cells were washed three times with 0·85 per cent sodium chloride solution and were centrifuged off each time at 11,000 r.p.m. They were then ground in a mortar (mounted in an ice bath) for 30 min. in the presence of 3·5 times their wet weight of alumina[6] ('Alorco F-20', minus 80 grade) and sufficient saline to result in a smooth, batter-like paste. After grinding, more saline was added to give a 4 : 1 ratio of saline volume (ml.) to wet cell-weight (gm.). The suspension was then centrifuged at 9,000 r.p.m. for 10 min. and the upper, cell-free, opalescent layer was used for the subsequent experiments.

Phosphorylation of xylose and glucose with adenosine triphosphate. Phosphorylation of xylose and glucose was studied with the aid of the manometric technique of Colowick and Kalckar[7] and by the disappearance of acid-labile phosphate following phosphorylation with adenosine triphosphate. The rate of carbon dioxide output was measured in the conventional manner using a Warburg apparatus.

The experimental system in which evidence of xylose phosphorylation was obtained was composed of: sodium bicarbonate 0·023 *M*; magnesium chloride 0·0033 *M*; sodium fluoride 0·02 *M*; D-xylose 0·02 *M*; cell-free extract 1·0 ml. and adenosine triphosphate 0·0033 *M* (added at zero time from the side arm, dissolved in bicarbonate). The adenosine triphosphate used was the sodium salt assayed at 89 per cent purity. Xylose was freshly recrystallized from aqueous ethanol before use. Measurements were made at 27° C. in 95 per cent nitrogen + 5 per cent carbon dioxide in a total volume of 3·0 ml.

Control experiments which contained (*a*) no sugar and (*b*) no extract were always run. The resultant values from the controls were subtracted from the experimental figures to correct for the small adenosine triphosphatase activity of the extracts and the slight change in gas volume produced on tipping the adenosine triphosphate into the main compartment of the manometric vessels.

The results of phosphorylation by an extract from *Pseudomonas hydrophila* obtained following the fourth transfer of the organisms into fresh synthetic medium are given in Fig. 1. It was found that the initial rate of xylose phosphorylation was always greater than that of glucose, and that upon repeated transfers of the organisms into fresh medium the xylose-phosphorylating activity remained unchanged, whereas the hexokinase activity decreased slowly to a relatively constant value.

The disappearance of acid-labile phosphate resulting from phosphorylation was measured by the method of Fiske and Subbarow[8]. Assuming that the reaction product was an acid-stable phosphate, the determinations were carried out on filtrates obtained by treatment with 10 per cent trichloroacetic acid of the reaction mixtures following 40 min. of active phosphorylation under the same conditions used for the experiment presented in Fig. 1. Typical results following 7-min. hydrolysis in *N* hydrochloric acid are given in the accompanying table.

Removal of hexokinase activity from extracts containing xylokinase. Hexokinase activity was removed from the cell-free extracts of *P. hydrophila* by the

DETERMINATION OF ACID-LABILE PHOSPHATES

Contents of reaction mixtures*	Acid-labile phosphorus in sample (x)	Acid-labile phosphorus per vessel (ν)	Phosphorus transferred to the sugars (γ)

Extract + ATP + D-xylose	9·6	288	309
Extract + ATP + D-glucose	13 7	411	186

* This includes also sodium bicarbonate, magnesium chloride and sodium fluoride at the concentrations given in the text

preparation of acetone-dried powders of these extracts without, however, affecting the activity of the xylokinase. Seven volumes of cold acetone were used[6], and the resulting precipitate was washed five times with cold acetone. The precipitate was then dried quickly on a Büchner funnel for a few minutes, followed by drying for an hour *in vacuo* over calcium chloride. The resulting fine, white powder was found to be stable in the refrigerator when kept in a desiccator over calcium chloride at 4° C.

When suspended in water, the acetone-dried powder was devoid of hexokinase activity but contained the xylokinase in undiminished activity (Fig. 2). This preparation did not phosphorylate D-ribose (0·02 *M*), D- or L-arabinose (0 02 *M*) or L-lyxose (0·02 *M*). The results using D-arabinose or L-lyxose are not shown in Fig. 2, since the total carbon dioxide output in 30 min. was not more than 2 c.mm. Iodoacetate (0·01 *M*) inhibited xylokinase activity most strongly, and it was found necessary to add magnesium ions in order to obtain maximum activity. The addition of 0·02 *M* glucose to the acetone-dried powder which phosphorylated xylose had no effect upon the xylokinase activity. The results shown in Fig. 2 are net effects, since the appropriate controls for each vessel without any added sugar have been subtracted. Xylokinase is therefore specific for the phosphorylation of xylose and appears to require free sulphydryl groups and magnesium ions for activity.

The Michaelis constant for xylokinase was determined using a quantity of 40 mgm. of acetone-dried powder per vessel in the presence of the required reactants (described above) and was found to be 0·0023 *M* (for xylose).

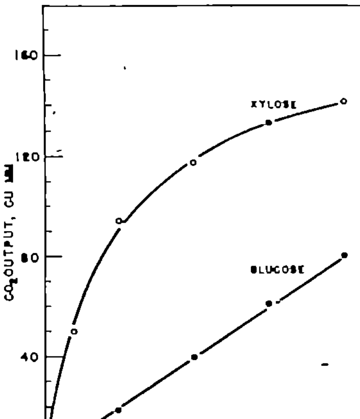

Fig. 1. Manometric estimation of the phosphorylation of D-xylose and D-glucose by a cell-free extract of *Pseudomonas hydrophila* in the presence of adenosine triphosphate

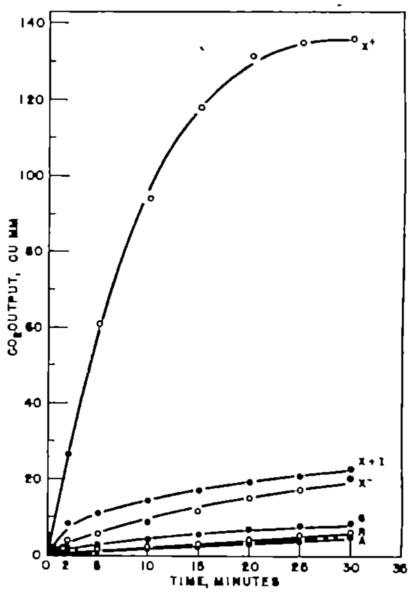

Fig 2. Manometric estimation of xylokinase activity, the effects of a variety of sugars, iodoacetate and magnesium ions. Quantity of acetone-dried powder used (per vessel), 30 mgm. *X*+ = D-xylose, *G* = D-glucose, *R* = D-ribose. *A* = L-arabinose; *X* + *I* = D-xylose plus iodoacetate; *X*⁻ = D-xylose without added magnesium ions

Nature of the phosphorylation product. The phosphate could be attached to the xylose molecule in one of several positions. On the basis of hydrolysis data given by Meagher and Hassid[10] and Levene and Raymond[11], it is established that: xylose-1-phosphate is 100 per cent hydrolysed when heated at 100° C. in *N* sulphuric acid for 10 min., whereas xylose-5-phosphate is only about 25 per cent hydrolysed when heated for 30 min. under the same conditions. Furthermore, the latter authors[11] were unsuccessful in their attempts to form a xylose-3-phosphate, since the ester always formed in the 5-position.

For purposes of the phosphate analyses reported here, heating was carried out at 100° C. in *N* hydrochloric acid for 7 min. and the reaction products kept in the form of trichloroacetic acid filtrates before the analyses were done. It would therefore appear likely that xylose-5-phosphate is the product of the xylokinase reaction. However, attempts to isolate and identify the end product and to elucidate the pathway of its metabolism are now in progress.

The technical assistance of Mr. Raymond Lapointe is gratefully acknowledged.

Electron Microscope Studies on Thin Sections of Human Erythrocytes

LITTLE is known about the inner structure of red blood cells. There are two main theories. One considers that the interior is a sponge-like network formed by structural proteins with the hæmoglobin n its intermicellar spaces. The other considers the erythrocyte as a balloon, containing free hæmoglobin n solution. Theoretical considerations, however[1,2], have shown that the blood pigment must be densely packed, and its degree of freedom is small, as follows from X-ray diffusion studies[3].

Direct observations by means of polarization[4,5] and especially electron microscopy[6-10] were successful for investigations of the membrane from 'ghosts' (hæmolysed cells) but failed to reveal the intact interior architecure. On one hand, no birefringence can be found there except in special cases[11,12], where hæmoglobin seems o exist in a *para*-crystalline or crystalline state; on he other hand, the non-hæmolysed erythrocyte is oo thick to be examined under the electron microoope. The only way to study these cells was to obtain sections thin enough to be penetrated by the electron beam. But whereas sections of 0·4–0·2 µ commonly used in electron microscopy are transparent enough to study epithelial or mesenchymal cells, all the erythrocytes in the blood vessels of the ame specimens remain homogeneously black or darkgrey. In a new series of experiments fresh blood clots fixed in 2 per cent osmic acid and embedded in Esterwax' were cut with a special microtome ('Rockng' Special Microtome, Cambridge Instrument Co., Ltd., Cambridge) at regular intervals without mechanical advance (4–5 movements for one tooth of the atchet wheel), according to a technique described lsewhere[13].

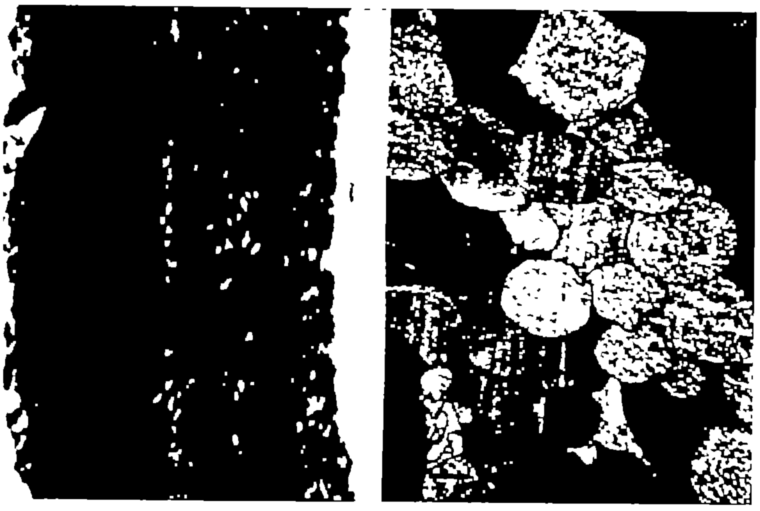
Though the 'Rocking' microtome is constructed or 0·2-µ thick sections only, after some attempts we were often able to get much thinner ones (0·1–0·025 µ, measured with latex-particles on shadow-cast grids). These specimens, the thinnest of which reached a hundredth of the normal red cell thickness only, were now transparent enough for our studies. Summarizing the observations, we can state that:

(1) *Without shadow-casting*, the osmium-fixed, non-hæmolysed human erythrocytes appear to be mostly homogeneous, densely packed without any visible structure. Some of them, however, show isolated denser irregularly dispersed spots. A very fine membrane of more definite osmiophilic character may be seen on the same fragments.

(2) *On shadow-cast sections*, the dense, homogeneous structure is of a granular (40 per cent), mostly filamentous (60 per cent) appearance (Fig. *a*). The filaments are 150–300 A. thick and show special orientation: on about half of the micrographs they are perpendicular, on one-tenth parallel, to knife incidence, on one-fifth they take an intermediate position, and the last fifth of the patterns show filamentous bundles crossed by others at certain angles (90°–150°). It has not been possible until now to find any constant relations between the direction of the filaments and the surface of the red cell. Though the high orderliness of the sub-microscopic structure is evident in the cut fragments, the architecture of the whole erythrocyte still remains to be elucidated, because ultra-thin sectioning generally breaks the red cell into fragments and it is almost impossible to say to which part the isolated fragment belongs, and at which level it has been cut. No findings, however, indicate entirely different zones in inner or outer parts of the red-blood cells, nor could isolated globular hæmoglobin molecules be distinguished, though they should become visible within these magnifications (38 A. of diameter, 75 A. of intermolecular distance after Ponder). When granules appeared, their diameter was about 200 A.; but it may be that they are, in fact, cross-sections of filaments representing a whole hæmoglobin lipoprotein complex.

(3) The membrane of the non-hæmolysed erythrocyte seems to be thinner than that of the ghosts, but its real thickness is very difficult to evaluate. The thinner the section, the less visible is the membrane. Nevertheless, it was not possible to show anything resembling the well-defined nuclear membrane of tissue cells. Measurements of the thinnest parts of the peripheral fragments show it to be 160 A. thick; on other areas it measures up to 320 A. No special structure, whether in the membrane itself or in the layers beneath, was visible. Sometimes the surface did not show any membrane at all.

(4) As soon as osmotic hæmolysis begins, the dense structure of the interior becomes clear and easily transparent. A very fine regular network appears and becomes coarse and irregular as the process proceeds (Fig. *b*). All the corpuscles are then delimited by a clearly visible sheet of 300-800 A. in thickness. The inner structure does not always lose its hæmoglobin with regularity. Some parts,



(*a*) (*b*)

) Thin section (about 0·05 µ) of a red cell fragment. *m*, Membrane. Filamentous ructures parallel to knife incidence. Shadow cast with gold-palladium. (× 31,000).
) Fine section of a blood clot. Partial hæmolysis (dist. water) with all the intermediate states from intact to almost empty cells. (× 3,800)

especially the thickened circumference, remain denser than others and disappear only when hæmolysis is complete. The erythrocyte is then entirely empty.

(5) From these observations, we can conclude that the intact red-blood cell has an extremely dense internal structure of granular or filamentous appearance, when fixed with osmic acid. There often exists a striking orderliness in its architecture. A spongy network and a well-defined membrane appear only when hæmolysis sets in. The completely hæmolysed erythrocyte is empty and balloon-like. Further details will be published elsewhere.

I am indebted to Dr. E. Ponder and Dr. D. G. Derwichian for an interesting discussion which encouraged me to continue the first investigations.

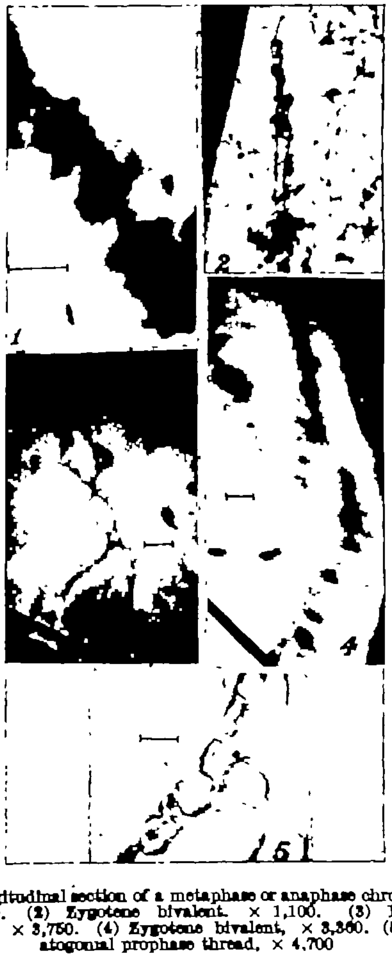
Electron Microscopic Study of Grasshopper Chromosomes

THE various methods used so far in preparing chromosomes for electron microscopy can broadly be classified into the following three categories: (1) cutting ultra-thin sections, (2) isolation of chromosomes, and (3) making squash preparations. Electron micrographs of the chromosomes of grasshoppers have been made by employing all these techniques. The material consisted of the spermatogonial cells and spermatocytes from the testes of adult male grasshoppers. The micrographs were taken by means of the new electron microscope installed in the Institute of Nuclear Physics, Calcutta, details of which have been published elsewhere[1]. Comparatively low magnifications were used purposely because we did not like the chromosomes to be magnified beyond recognition in our first attempt.

Fig. 1 is an electron micrograph from a sectioned preparation of the testes made after the method described by Pease and Baker[2]. The section has passed longitudinally through a portion of a compact, cylindrical, helically coiled chromosome probably of the metaphase or anaphase stage and the transverse disks are consequently interpreted as the gyres of the spiral. The coiled chromosome seems to possess a conspicuous coating of a substance much more transparent to the electron beams than the disks themselves. Fig. 2 is a similar micrograph of a pair of isolated chromosomes in the zygotene stage obtained by following the technique of isolation similar to that suggested by Claude and Potter[3]. Although they were extracted from the spermatocytes by a rather drastic procedure of crushing the cells with sand particles, the identity of the chromosomes in the micrograph is beyond any reasonable doubt. The comparatively large dark bodies on the threads are due to the adherent sand particles which could not be removed by washing. The individual chromosomes show distinct chromomeric structure in the portion which is comparatively free from sand particles. The chromomeres on the homologous chromosomes are more or less similar in size, thus indicating their homologous nature. The paired chromosomes appear to be split at one end, where four distinct threads with chromomeres are seen. The future development of better technique for the electron microscopy of chromosomes might be of great use in deciding not only between the conflicting points of view regarding the reality or otherwise of ultimate chromomeres but also regarding the determination of the number of chromonemata present in a chromosome in the different stages of the division cycle.

While trying to use the technique proposed by Schultz *et al.*[4] we developed some modifications which gave us consistently good micrographs. The testes of male grasshoppers were dissected out in isotonic sodium chloride solution and fixed in Carnoy's fluid before storing them in 70 per cent alcohol. When preparing a specimen for the electron microscope, one of the lobules was stained either in aceto-carmine or in Feulgen's stain. The stained specimen



(1) Longitudinal section of a metaphase or anaphase chromosome, × 8,000. (2) Zygotene bivalent. × 1,100. (3) Diplotene bivalent, × 3,750. (4) Zygotene bivalent, × 3,360. (5) Spermatogonial prophase thread, × 4,700

was transferred to 45 per cent acetic acid before making the squash, which was done on glass slides previously coated with a thin layer of collodion diluted 1 : 6. The cover-glass was at first gently pressed with the thumb, followed by a pressure with a C-clamp for the maximum stretching of the chromosomes. The slide with the cover-glass in position was placed on an ice block and, when sufficiently chilled, the cover-glass was prised off with a dissecting needle. This chilling helped in the retention of materials on the collodion film, which was then stripped off. In order to mount the desired part on the specimen grid, the stripped film was mounted on a clear slide with a film of water in between the film and the slide. The useful portion was selected under the optical microscope and separated with a sharp blade of a scalpel. The film was again floated on water and finally mounted on the specimen grid of the electron microscope.

Several electron micrographs were taken from squashes prepared by this method. Fig. 3 is a micrograph of a diplotene bivalent and it is clear that the structural details are more or less faithfully preserved. Fig. 4 represents a zygotene bivalent showing the chromomeric structures. A portion of the bivalent remains unpaired, and the structure of the chromomeres indicates the non-homologous nature of the unpaired portion. Fig. 5 perhaps represents an early prophase thread of spermatogonial divisional stages. The spiral structure seems to be the relic coiling, and an indication of longitudinal split in the chromosome is quite evident. The absence of differentiation into chromomere and interchromomere regions, in contrast with the prophase threads of meiosis, is a characteristic of the early mitotic chromosomes of the grasshoppers. Further work is in progress.

We wish to thank Prof. M. N. Saha and Dr. N. N. Das Gupta for their interest in the work, and to the Ministry of Education, Government of India, for financial assistance.

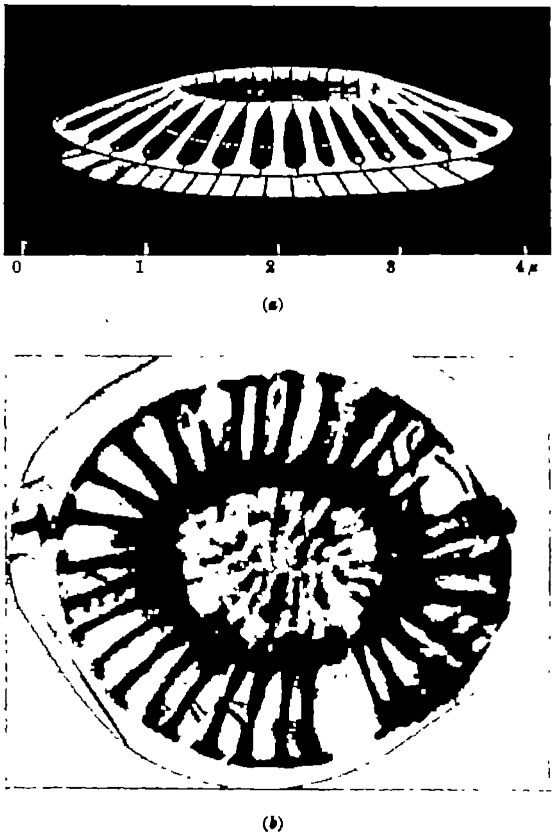
Coccoliths of *Coccolithus huxleyi* seen in an Electron Microscope

THE taxonomy of Coccolithophoridaceæ is based upon the morphology of the coccoliths. On account of the minute size of most of the coccoliths it has not been possible to obtain satisfactory pictures of them, even with the best optical equipment. This has caused confusion in the classification of coccolithophorids. It is illustrative that the most abundant and common species, *Pontosphæra huxleyi* Lohm., has been shown to include three taxonomical units with different coccoliths[1]. One is referred to the new genus *Gephyrocapsa* Kamptner, the others to *Coccolithus* Schwartz.



(a) Diagram of coccolith of *Coccolithus huxleyi*. (b) Coccolith seen from above. Photomicrograph by means of the electron microscope. (Photo. T. Markali)

In collaboration with Mr. Toar Markali, of the Central Institute of Industrial Research, Oslo, we have been able to study the coccoliths of *Coccolithus* (*Pontosphæra*) *huxleyi* (Lohm.) Kamptner in an electron microscope. The coccoliths came from a unialgal culture of this species, started by the junior author during a stay on board weather ship *M.* off Norway last summer.

Fig. *a* shows a diagrammatic drawing of a coccolith, according to information obtained by means of the electron microscope and a Leitz phase-contrast microscope. Fig. *b* is a photomicrograph taken in the electron microscope of a coccolith seen from above. The thin lower disk can be seen through the central opening in the upper disk. The picture shows the following new details in the structure of the coccolith. (1) The upper disk consists of a large number of radial elements, which, on their inner end, also form a cylindrical connexion with the lower disk. (2) The lower disk does not have a central opening corresponding to that of the upper one. This last feature is of special taxonomic interest, since it is in contradiction to the definition of the tremalith, the coccolith type which includes the placoliths of *Coccolithus*.

A further study of a number of coccolithophorids by this method may be expected to necessitate a redefinition of the various types of coccoliths and possibly also a reclassification of Coccolithophoridaceæ.

A more detailed description of the coccoliths in *Coccolithus huxleyi* and *Syracosphaera carterae* is being prepared by us in collaboration with K. Ringdal Gaarder and T. Markali for publication in *Nytt Magasin for Botanikk*.

Statistical Theory of Atomic Nuclei

STATISTICAL methods have been applied to the explanation of the properties of atomic nuclei for quite a long time[1]. Hitherto, the energy of nuclei could be represented only in such a way that, according to the choice of the empirical parameters in the interaction energy of the nucleons, either for light nuclei or for heavy ones, the calculated values show noticeable discrepancies from the experimental values.

The purpose of the present communication is to calculate the binding energy of nuclei according to the statistical theory, assuming a scalar Yukawa potential for the nucleon interaction. The calculations are carried out on the general principle of the minimization of energy with the help of Ritz's method, without any arbitrary assumptions. We have supposed that the part of the interaction energy which depends only on the mutual distance of the nucleons is the same for the neutron–proton, neutron–neutron and proton–proton interaction and has the form:

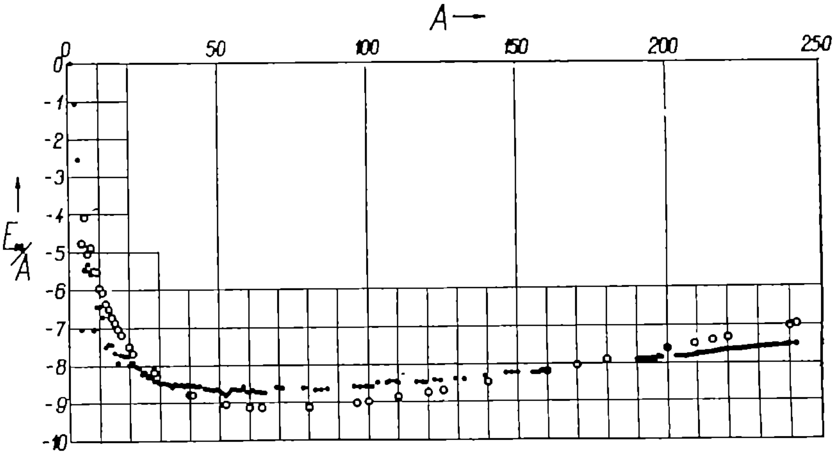
$$J(r_{ik}) = -\gamma\,\frac{\exp(-r_{ik}/r_0)}{r_{ik}}, \qquad (1)$$

where r_{ik} denotes the mutual distance of two nucleons, r_0 the Compton wave-length of the π-mesons and γ an empirical constant. If for the mass of the π-mesons, M_π, the value of 285 electron masses is chosen—a value experimentally obtained by Powell and his collaborators[2]—one has

$$r_0 = \frac{h}{2\pi M_\pi c} = 1{,}355 \times 10^{-13}\ \text{cm.}, \qquad (2)$$

where h denotes the Planck constant and c the velocity of light.

For the attractive energy between the nucleons, a pure exchange energy has been assumed. As further energy terms of the statistical nucleus, we have taken into account the kinetic zero-point Fermi energy, the kinetic inhomogeneity correction of Weizsäcker and further the Coulomb repulsive energy of protons as well as the Coulomb exchange interaction energy between protons, arising from the Coulomb interaction of protons[3]. All these energy terms are functions of the neutron density $\rho_n(r)$ and proton density $\rho_p(r)$, where r is the distance from the centre of the nucleus.



Nuclear energy per nucleon, E_{n}/A, as a function of the mass number A.
O, calculated values, ●, empirical values for stable nuclei; ○, empirical values for unstable nuclei

Our task is to determine the density distributions which make the total energy of the nuclei a minimum. The density distributions must fulfil the following conditions: first, the density distributions must be normalized with respect to the given number of neutrons and protons in the nucleus; secondly, at great distances from the nucleus, the density distributions must rapidly decrease to zero; and thirdly, for reasons of symmetry, the slope of the density distributions must vanish in the centre of the nucleus.

The first step of the Ritz method consists in setting up for the density distributions the following functions:

$$\begin{aligned}\rho_n(r) &= \rho_{n0}\exp(-a^2r^2/r_0^2)\\ \rho_p(r) &= \rho_{p0}\exp(-a^2r^2/r_0^2),\end{aligned} \qquad (3)$$

where a denotes a variational parameter and ρ_{n0} and ρ_{p0} are normalizing factors. For these one obtains, from the normalizing conditions, $\rho_{n0} = Na^3/(\pi^{3/2}r_0^3)$ and $\rho_{p0} = Za^3/(\pi^{3/2}r_0^3)$, where N and Z denote the number of neutrons and protons respectively. According to (3), in the first approximation, the density distributions of neutrons and protons have been assumed to be equal, and a difference between the two density functions has been taken into account only inasmuch as the normalizing constants ρ_{n0} and ρ_{p0} are generally different because, except in the case of light stable nuclei, N is not equal to Z. Inserting the density functions in the energy expression, the energy becomes a function of the variational parameter a, which can be determined from minimization of the energy.

In the whole theory the only empirical parameter is the constant γ in (1). It will be shown that, by an adequate choice of this single parameter for the binding energy of nuclei, results can be obtained which are, from the lightest to the heaviest nuclei, in very good agreement with the experimental results. The discrepancies between the calculated values and the empirical ones are, except for very light nuclei, less than 7 per cent; for very light nuclei, the binding energy of which is not a monotonic function of the mass number, the statistical theory can give, of course, only a mean value of the strongly fluctuating empirical value, which is actually achieved by the statistical theory. In the accompanying diagram, for given mass numbers A, the calculated values of the nuclear energies per nucleon, E_{0s}/A, of the nuclei with the deepest energy are represented with the empirical ones[4].

The atomic numbers Z of the nuclei with the highest energy for given mass numbers A are also very satisfactorily obtained by means of the theory, the discrepancy between them and the empirical atomic numbers being throughout smaller than 8 per cent.

That the statistical theory developed here—applicable, according to its character, in the first place to nuclei of large mass number—offers such good results also for light nuclei is to be attributed to the fact that we have introduced two corrections. On one hand, we have eliminated from the statistical expression of the exchange interaction energy of equal nucleons the energy resulting from the self-exchange of the nucleons. On the other hand, a correction has been introduced for the kinetic energy whereby the statistical kinetic energy for the nucleus ^{4}He and for lighter nuclei goes over into the exact wave-mechanical expression. By the use of these corrections, the statistical expression of the total energy of light nuclei is found to approximate closely to the wave-mechanical expression and gives a good mean value for the empirical results.

A detailed account of this work will be given in the *Acta Physica Hungarica*.

Cores of Terrestrial Planets

ONE feature of Prof. H. C. Urey's new theory[1] of the development of the planets is that it leads him to conclude on several grounds that the earth's central core has an iron composition. This conclusion is in conflict with Ramsey's proposal[2] that the density throughout the earth's deep interior, at least below a depth of 1,000 km., is essentially determined by pressure right through to the earth's centre rather than by change of chemical composition. The conclusion as stated is also in conflict, though to a less degree, with my proposals, which differ from Ramsey's through finding a balance of evidence[3] in favour of a separate chemical composition, such as nickel–iron with possibly some denser material, for the earth's *inner* core, but agree with Ramsey's in postulating a modified ultrabasic rock composition for the outer part of the core, that is, between depths of 2,900 km. and 4,980 km.—the region that I have referred to[4] as 'E'; the latter postulate will be referred to as α. On the further hypothesis, β say, that the terrestrial planets have a common primitive composition, Ramsey's theory implies that neither Venus, Mars nor Mercury has an inner core, whereas my work favours the view that all three have inner cores.

The purpose of this communication is to show that evidence can be brought to bear to qualify a number of the arguments by which Urey infers an iron composition for the region E. At the same time, it is interesting that strong new support is found for the suggestion that the inner core is chemically distinct from the rest of the earth. Four main points will be considered, as follow:

(1) Urey appears to accept Elsasser's conclusion[5], based on Bridgman's experimental results and calculations of Feynman, Metropolis and Teller[6], using a Thomas–Fermi–Dirac model, that a silicate composition for the region E "appears to be excluded". I have recently shown, however, that Elsasser's calculations are unsatisfactory in an important particular, a criticism which has been accepted by Elsasser (in a personal communication). My investigation leads me to the view that, on balance, the data of Bridgman and of Feynman, Metropolis and Teller tend slightly to favour a silicate composition for the region E, although they do not provide a crucial test. The details, which are intricate, are being published elsewhere.

(2) Urey considers that the mass and radius of Venus are so similar to those for the earth "that they can be made to fit any theory that accounts for the Earth". Actually, calculations by Jeffreys[7] on Venus show that, on the assumption β, the hypothesis that the region E is chemically distinct from the mantle is untenable; the hypothesis yields 1 : 5·6 for the ratio of the mass of the central core of Venus to the total mass of Venus, as against a ratio of 1 : 4·1 for the earth. This discrepancy is in significant contrast to the measure of agreement obtained with observational data on Venus by Ramsey and myself on the opposite hypothesis α.

(3) In respect of Mars, Urey directs attention to the discrepancy found by Ramsey in fitting this planet to the hypotheses α and β. But I have shown[4,8] that if use is made of the earth model B[8], constructed from the hypothesis[9] that compressibility is a smooth function of pressure through the earth's deep interior, then α and β fit the observed radius, mass and ellipticity of Mars within the standard errors of observation. I am repeating these calculations using revised observational data quoted by Urey, but unless the revision brings to light unexpected changes, Mars must be regarded as giving good support to α and β, the earth model B having been constructed without any *ad hoc* adjustment to fit planetary data.

(4) Observational data on Mercury prior to 1950 were considered to be too imprecise to be used as a test of α and β. Rabe's recent calculations[10], based on the perturbations of Eros, give the mass of Mercury as 0·0543 times that of the earth, an increase of order 20 per cent from the previous estimate. Estimates of the value of Mercury's diameter are still very uncertain, and, taken along with Rabe's value of the mass, lead to estimates of the mean density ranging from 4·6 to 5·2 gm./cm.^{3}. Such values are incompatible with the possibility that Mercury may have the same mean density at zero pressure as other planets, and Urey interprets this as a further test against the presence of a silicate core in the earth.

If Rabe's revision is accepted, it is necessary to accept with fairly high probability that, in relation to the hypothesis β, Mercury is an exceptional planet in some important respect; only a considerable future upward revision of estimates of Mercury's diameter could affect this conclusion. But Mercury may still be exceptional in this respect and yet at the same time compatible with α and β.

An obvious exceptional feature of Mercury is that it is the nearest planet to the sun, and it now turns the same face to the sun. According to radiometric measurements, the present temperature of the subsolar point at perihelion is 685° K., and the molecular weight of escaping molecules at this point would be about 70. This would permit the escape of some of the ingredients of an initial rocky mantle provided they could be volatilized sufficiently readily. Various mechanisms could be suggested for bringing about the temperature necessary for such volatilization; of these perhaps the most likely is that, earlier in the history of the solar system, the orbit of Mercury was much more eccentric than now and that Mercury was once much nearer the sun at perihelion. The suggestion then emerges that Mercury may well have lost not merely a normal atmosphere, but also an appreciable proportion of an initial rocky mantle, by volatilization and subsequent escape, and that Mercury was thus once a considerably larger planet.

On this suggestion, Mercury could still have the same primitive composition as the earth, Venus and Mars, and the region *E* of the earth could still be modified silicate rock. In fact, on this set of assumptions, it should be possible (subject, of course, to a number of uncertainties, including the uncertainty of the value of Mercury's diameter) to estimate the mass of the primitive Mercury; it is hoped to present this estimate in a later paper.

The suggestion here made may possibly bear some relation to the mechanism which Urey proposes, in his theory, for the fractionation of silicate and iron phases in various planets, taken in conjunction with the statement in his main thesis "that the primitive planets consisted of a grossly homogeneous mixture of silicate and iron phases". The statement quoted is consistent with hypothesis β and is consistent with ideas I have favoured. But the possible significance of Mercury's proximity to the sun leads me to question whether the present mean density of Mercury can properly be used for discriminating in favour of a predominance of the iron phase in the region *E* of the earth.

On the other hand, it would seem that the probability is now increased against that part of Ramsey's view which holds that the earth's inner core is essentially a second pressure modification of ultrabasic rock. On Ramsey's view, Mercury has no core, and Urey's criticism cannot be so readily met by assuming a substantial loss of material in the course of Mercury's evolution. A substantial loss would imply the presence of a modified-silicate core in the primitive Mercury, and, in the absence of a chemically distinct inner core, loss of the core would lower the mean density appreciably.

On the question of the difference between the views of Ramsey and myself, it may be stated that all available astronomical evidence now favours a distinct chemical composition for the earth's inner core. The observational data on all four of (*a*) the mass and diameter of Venus, (*b*) the mass and diameter of Mars, (*c*) the figure of Mars, and (*d*) the mass and diameter of Mercury, independently favour the presence of inner cores in these planets.

It has already been suggested by Jeffreys[11] that Urey's stimulating theory, which rests in large part on arguments from physical chemistry, may need some modifications in order to meet arguments from other sources; and it will be of interest to know how far hypothesis α can be fitted into Urey's theory of the origin of the planets without disturbing other important conclusions.

Radio-Frequency Radiation from Tycho Brahe's Supernova (A.D. 1572)

Since the discovery of localized sources of extra-terrestrial radio-frequency radiation in 1948[1], surveys have been carried out over the whole sky[2,3] and the positions and intensities of about one hundred sources are now known. Although a few of these sources have been identified with extra-galactic nebulæ[3-5], it is generally considered that the majority must lie within the Galaxy with a distribution, and perhaps a density, similar to that of the common visual stars[6]. However, it has not yet been possible to associate the radio sources with any class of visual objects in the Galaxy, and in only one instance has an identification been made, namely, the identification of a source in Taurus with the Crab nebula[7]. As the Crab nebula is believed to be the remnant of the supernova of 1054, it is to be expected that the remnants of other supernovæ are also sources of radio radiation. The other supernovæ known to have occurred in the Galaxy are those of 1572 and 1604 but the published surveys show no radio source in either of these positions.

Recently, a detailed survey[8] has been made of the region of the sky which lies within the field of view of the 218-ft. paraboloid at the Jodrell Bank Experimental Station. The observations have been made at 158·5 Mc./s., and at this frequency the aerial has a beam-width of 2° between half-power points. In this survey a number of localized sources of radiation have been detected, several of which have not been reported previously. The co-ordinates of one of these sources agree closely with those of the supernova of 1572, as shown in Table 1, and in view of this agreement the radio source may be tentatively identified with the remnant of the supernova.

Table 1. Data on Radio Source and Supernova (1572) Epoch 195

	R.A.	Declination	Intensity*
Radio source	00h. 21m. 49s. ±2m.	N. 64° 15′ ±35′	1·7 × 10^{-24} W./sq.m./c/s. ± 25 per cent
Supernova of 1572 (ref. 10)	00h. 22m. 0·2s.	N. 63° 52′ 12″	

* The intensity given is twice that observed in one plane of polarization.

The chief difficulty in observing this source lies in its proximity to the intense source Cassiopeia I (R.A. 23h. 21m. 12s., declination N. 58° 32′, Epoch 1950 [5]), and when it was first observed in 1951 there was some doubt as to whether it was genuine, or represented the reception of the nearby intense source in a side lobe of the aerial beam. This doubt has now been removed by means of a special interferometer which observed the two sources simultaneously, and showed that the radiation received from the source in the position of the supernova is incoherent with that received from Cassiopeia I. The proximity of this source to Cassiopeia I presumably explains why it was not reported in the survey made with an interferometer at 81 Mc./s. by Ryle, Smith and Elsmore[3].

Table 2 shows a comparison between the visual data available for the supernovæ of 1054 and 1572 and the intensities of the associated radio sources.

Table 2. COMPARISON OF THE SUPERNOVÆ OF 1054 AND 1572

Supernova	Apparent visual magnitude at maximum brightness	Apparent integrated photographic magnitude of remnant	Intensity* of associated radio source (watts/sq. m./cps.)
A.D. 1054	−6·5 to −7·0 (ref. 9)	+9 (ref. 10)	19×10^{-24}†
A.D. 1572	~ −4 0	> +15 (ref. 11)	$1{\cdot}7 \times 10^{-24}$

* The intensity is given for 158·5 Mc./s. and is twice that observed in one plane of polarization.

† This intensity is taken from the spectrum of the radio source given by Stanley and Slee (ref. 2).

No visible remnant of the supernova of 1572 has yet been observed, and the integrated photographic magnitude given in Table 2 represents the upper limit to the intensity, as estimated by Baade[11].

There is a difference of about 2·5 magnitudes between the intensities of the two radio sources, and this is equal to the difference between the apparent visual magnitudes reached by the supernovæ at maximum brightness. There is, however, a much greater difference of at least 6 magnitudes between the integrated photographic magnitudes of the remnants of the supernovæ. In view of the present lack of knowledge of the processes involved both in a supernova and in the emission of radio-frequency radiation from a localized source, it is not possible to offer any explanation of this discrepancy.

The discovery of a source in the position of the supernova (1572) supports the conclusion, originally based only on the observation of a source in the position of the Crab nebula[7], that the remnant of a supernova is a source of intense radio-frequency radiation. This phenomenon is of great interest since no satisfactory mechanism for the generation of the radiation has yet been proposed. Further evidence could be gained by a careful search for a radio source in the position of the supernova of 1604, which unfortunately lies outside the field of the 218-ft. paraboloid. The region has already been surveyed by Stanley and Slee[2] at 100 Mc./s., and no source in this position has been reported. However, their survey had a limit of detection of about 10^{-24} W./sq. m./cps., and the present results indicate that a source in the position of the supernova (1604) may have been overlooked.

The work has been carried out at the Jodrell Bank Experimental Station of the University of Manchester. We wish to thank Prof. Z. Kopal for directing our attention to the problem and Prof. A. C. B. Lovell for his interest in the investigation. One of us (R. H. B.) is indebted to Imperial Chemical Industries, Ltd., for a research fellowship, and the other (C. H.) to the Department of Scientific and Industrial Research for a maintenance grant.

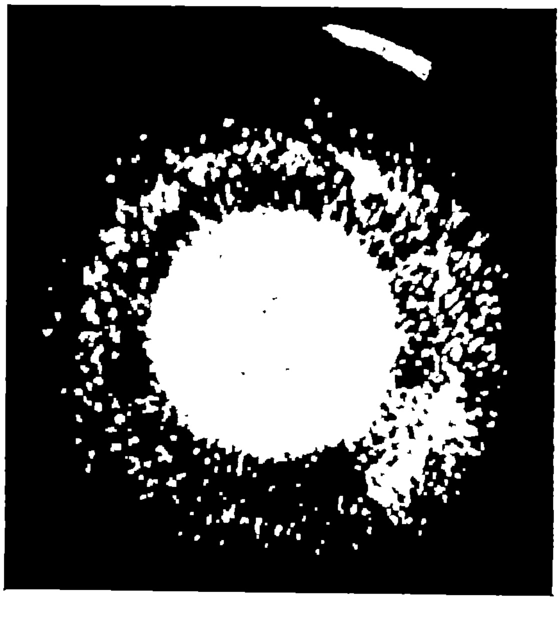
Radio Echoes and Lightning

OBSERVATIONS are being made by 10-cm. radar at Salisbury, Southern Rhodesia, on distant and overhead storms and rain clouds.

On one occasion with a thunderstorm passing overhead, the vertically directed radar beam gave several unusual echoes which occurred simultaneously with lightning flashes. The echoes were recorded by a time-lapse camera used to photograph the P.P.I. screen. A copy of one of these photographs is reproduced herewith. It shows a circularly symmetrical precipitation echo, and a lightning echo appears as a curved streak of unusual brightness. In this particular case the height of the echo base above ground was 26,600 ft., the vertical depth of echo was 1,900 ft. and the echo duration 0 39 sec. The temperature at this level, from the early-morning *radio-sonde* sounding, was − 26½° C. Rotation of the P.P.I. scan was anticlockwise.

In other photographs obtained, but less suitable for reproduction, two echoes occurred concurrently and separated by varying intervals of height.



The echoes are being analysed in terms of the individual strokes comprising a discharge to ground, with special reference to the junction-streamer process described in a recent paper by Malan and Schonland[1]. It is suggested that the echoes originate from ionized portions of the cloud charge. A detailed paper is being prepared for publication.

Anomalous Properties in Quartz

Attempts to estimate quartz in certain New Zealand clays by the differential thermal method have revealed the occurrence of a variety with abnormal inversion properties.

The phenomenon was first observed[1] in clays occurring in the North Auckland peninsula as residual deposits formed by the weathering of dacite and rhyolite flows. These clays consist of 40–60 per cent of quartz, the balance being halloysite with minor amounts of felspars and accessory minerals. The quartz exists in two forms, one of which shows the normal α ⇌ β inversion at 573° C., while in the other form the inversion is more sluggish than usual and occurs at 555–560° C. The abnormal form is usually concentrated in the sizes below 75 microns.

Since the original observation in 1945, similar phenomena have been observed in decomposed rhyolite at Mount Somers, South Canterbury, and in well-weathered greywacke at Glen Massey, New-castle Survey District. The associated clay mineral in these cases is kaolinite. In the North Auckland occurrences cristobalite and tridymite are frequently present.

When treated by the pyrosulphate fusion technique of Trostel and Wynne[2], the 0–10 micron fraction of clay from Parua Bay, Whangarei, yields pure quartz of the low-temperature (560° C.) inversion type. Measurements on this material show: (1) chemical composition, 99·3 per cent SiO_2; (2) X-ray diffraction pattern indistinguishable from normal quartz; (3) thermal expansion curve of the quartz type, but with a total expansion at 600° C. of 0·85 per cent, as against 1·10 per cent for normal quartz of the same particle-size; (4) the α ⇌ β inversion although more sluggish than normal, and the accompanying heat effect approximately half the normal value; (5) normal conversion to cristobalite above 1,470° C.

The evidence indicates that there exists a modification of quartz in which the mechanism of inversion differs from the normal. The ceramic implications of this observation will be obvious, and in particular the use of the differential thermal method for the quantitative estimation of quartz requires more critical consideration than it has hitherto received.

Abnormal Thermal Behaviour of α-Quartz from some New Zealand Soils

In 1947, McDowall and Dunn[1] reported the differential thermal curves for free quartz in eigh New Zealand clay deposits. They pointed out tha the peaks of the α–β inversion were broader than those of quartz–alumina mixtures, and that in one case a small sharp peak at 573° C. was associated with a broader one at 555–560° C., resulting in an unusua double peak. The properties of these unusual forms of quartz are further described by McDowall and Vose[2].

In 1948, during an investigation of minerals in New Zealand soils, a number of soils were found to contain a form of quartz which, although shown by X-ray to be normal, well-organized α-quartz failed to give the usual pronounced thermal effec due to α ⇌ β inversion in differential thermal analysis The soils in which this form of quartz occurs include Mangatea silt loam from Katoa, Whirinoki clay loam from Hokianga, and Puhoi clay loam from Waiwera These are weakly or moderately leached yellow-brown earths derived from sandstone or mudstone. They occur in locations some hundreds of miles apart and there is no suggestion at present that their parent material has a common origin. Their mineral colloids contain appreciable amounts of quartz, illite and montmorillonite. Quartz is highest in their silt fractions (between 2 and 20 microns equivalent diameter).

Characteristic behaviour is illustrated by the quartz from the silt fraction of the *B* horizon of the Mangatea silt loam. This silt appeared from X-ray diffraction to contain about 50 per cent of α-quartz, but its thermal pattern, judged by peak height and area corresponded to less than 5 per cent of α-quartz 53 per cent of free silica was separated from the silt by the pyrosulphate fusion method of Trostel and Wynne[3]. The separated material contained more than 99 per cent of SiO_2 and appeared from X-ray diffraction to consist almost entirely of α-quartz but its thermal pattern corresponded to less than 10 per cent of α-quartz.

This form of quartz differs from the form of quartz in clay deposits described by McDowall and Vose[2]. The quartz from clay deposits has broadened peaks in the neighbourhood of 560° C., whereas the form from soils has a characteristic peak at 573° C. much smaller than that expected from the amount of α-quartz present. The thermal expansion of the quartz from clay is abnormal, whereas that of the soil quartz is normal. Cristobalite and tridymite are present in the quartz from some of the clay deposits but none is detected in the soil quartz, although cristobalite has sometimes been reported in soils containing montmorillonite.

Berkelhamer[4] has stated that chalcedony registers a perfect quartz X-ray pattern but gives a reaction at the α ⇌ β inversion point equal in magnitude to that produced by approximately 1–4 per cent of quartz. This result is confirmed with New Zealand samples of chalcedony.

Optical examination of the silica residue of Mangatea silt loam was made by Mr. J. J. Reed Geological Survey, New Zealand Department of Scientific and Industrial Research, who found that the sample contained a small amount of normal quartz, but consisted mainly of glassy isotropic material of refractive index 1·50, which is lower than that of chalcedony (1·537), the latter being ghtly lower than that of quartz (1·5442 and 5532).

It is possible that the small reactions at the inrsion point of both chalcedony and the glassy aterial described are due to the presence of some rmal quartz. It also seems that chalcedony may in some way intermediate between normal quartz d the glassy material.

The evidence of the quartz from clay deposits ows that it is possible for a thermal effect related the α ⇌ β inversion to occur at a lower temperature d more sluggishly than the normal change. Witht further evidence it is not possible to determine the behaviour of the quartz from soil and chalcedony related or a separate phenomenon.

Whatever the mechanisms of the thermal effects, is certain that the occurrence of the form of α-artz described above would cause errors in any antitative estimation of soil quartz based solely the differential thermal method.

Twin Flames

SINCE Wolfhard's spectroscopic investigations of e reactions in a widened combustion zone at reuced pressures[1], the appearance and disappearance a variety of chemical species in different regions the luminous zone of hydrocarbon Bunsen flames ave been demonstrated[2].

In the course of some studies on the effect of fuel dditives on the laminar flame velocity of hydrorbons burning in air at atmospheric pressure, we ave found that in mixtures of fuels of widely differg reaction velocities (propane and diborane), within rtain air – fuel limits, the reaction zone of a Bunsen ame separates into two distinct luminous regions (Figs. 1*A*, *B*, *C*). In this twin flame, the first luminous zone is believed to be due to the oxidation of diborane, the second to the oxidation of the hydrocarbon. As the air – fuel ratio is decreased, the diborane oxidation continues in a well-defined reaction front, and the hydrocarbon reaction zone disappears gradually and changes into a diffusion flame (Figs. 1*D*, *E*). Careful manipulation of the flow system enables one to quench the hydrocarbon reaction while still retaining the primary zone of the diborane oxidation. A plot of flame velocities (determined by the Smith–Pickering method[3]) with varying oxygen content in the mixture exhibits two maxima, one near the stoichiometric air – fuel ratio based on the total fuel, the other near the stoichiometric air – fuel ratio based on B_2H_6 – air, considering the hydrocarbon as non-reacting diluent (Fig. 2).

Sedimentation of Halloysite

IN the North Auckland peninsula of New Zealand there are extensive deposits of halloysitic clays formed by weathering of dacite. Attempts to determine the particle-size distribution of a well-crystallized sample from Matauri Bay, Whakarara Survey District, have revealed anomalous sedimentation behaviour.

A suspension having a concentration of 1 per cent by weight was prepared by tumbling for 16 hr. in 0·003 per cent sodium pyrophosphate solution, and the Andreasen pipette procedure was used to determine the concentration at 10, 5, 2 and 1 microns. The average of four determinations is given in the accompanying table.

PERCENTAGE OF HALLOYSITE REMAINING IN SUSPENSION AFTER SETTLING

Settling time (min.)	Nominal size (microns)	Percentage finer than size
16	10	97·3
62	5	97·7
355	2	97·4
1,760	1	97·5

Fig. 1, which is an electron micrograph of the top of the suspension after three days settling, shows that there are many large particles remaining in suspension and that the size distribution determined by the pipette method has no relation to the true size-range. On prolonged standing, a clear layer develops at the surface and is followed by a zone of rapidly increasing concentration. Fig. 2 is an electron micrograph of the suspension 1 cm. below the surface, and at the top of this cloudy layer after two months standing. Although generally finer than after three days standing, there are numerous particles of one micron and larger.

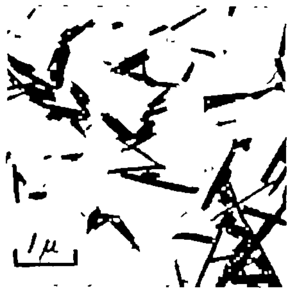

Fig. 1. After standing for three days

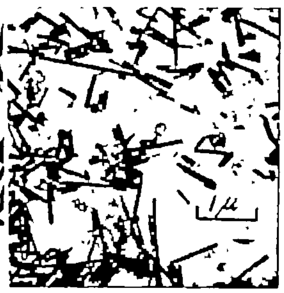

Fig. 2. After standing for two months

It is suggested that the long rod-shaped particles form a loose lattice structure in the suspension and that this impedes the settling of the particles. The slow decay of this lattice on standing leads to the formation of a clear layer at the surface.

The electron micrographs were prepared by Mr. K. I. Williamson, of the Dominion Physical Laboratory, Department of Scientific and Industrial Research, New Zealand, and our thanks are due to the Director of that Laboratory for permission to reproduce them.

Decomposition of Organic Matter by Recoil Atoms from an Adjacent Phase

DURING experiments involving the irradiation mixed powders of uranium oxide and graphite the Harwell pile, BEPO, we found evidence the decomposition of organic matter present in t graphite caused by fission processes occurring in t adjacent oxide phase.

'Ultra-fine' colloidal graphite powder from Mess Acheson, Ltd., was intimately mixed with an equ weight of uranium dioxide of 5 μ nominal partic size. The mixture was heated in vacuum at 200° for 4 hr. in a silica vessel prior to irradiation. Th vessel was connected by silica tubing to the Toepl pump outside the pile, so that gases evolved durin irradiation could be collected, measured and analyse by the Blacet–Leighton technique[1]. The rate evolution of gas could be determined by operatin the pump at regular intervals and measuring t length of bubble in the calibrated delivery capillar

The rate of evolution of gas showed immedia response to changes in pile power-level in a mann which suggested that thermal effects were not t cause. Moreover, the measured temperature und steady conditions at full power was only 75° C while the rate of gas evolution at 200° C. pri to irradiation was a negligible fraction of th experienced at full power.

Similar experiments with graphite alone, uraniu oxide alone, and with mixtures of zinc oxide an graphite gave very much smaller amounts of gas.

Material	Thermal neutron dose (n cm.$^{-2}$ × 10^{-17})	Gas evolved (mm.^{3}/gm graphite)
ZnO + graphite	16·5	0·5
Graphite	3·8	0·8
UO_2	4·3	81 (per gm. of UO_2)
UO_2 + graphite	3·8	1,332

This makes it clear that most of the gas evolve from the mixture of uranium oxide and graphite dependent on the fission process in the uranium oxid and that the material being decomposed is not in th uranium oxide phase. Fission fragments and th atoms which they displace evidently pass into th adjacent graphite phase and cause decomposition organic matter. The nature of this organic materi is unknown; but thermal tests above 500° C. hav shown the presence of appreciable organic impurit in the samples of graphite used.

It is interesting to note that for the mixtu of uranium oxide and graphite, the whole of th available energy of the fission fragment (mo of which would be lost in the uranium oxid phase) was only about 400 times the energy d posited in the graphite from pile neutron radi tion alone, yet the evolution of gas from th mixture was more than 1,600 times that from th graphite alone. Fission fragments and the ato which they displace are evidently much more efficie in causing the decomposition of organic matter tha the atoms displaced by neutron scattering.

Our thanks are due to the Director, Atom Energy Research Establishment, for permission publish this communication.

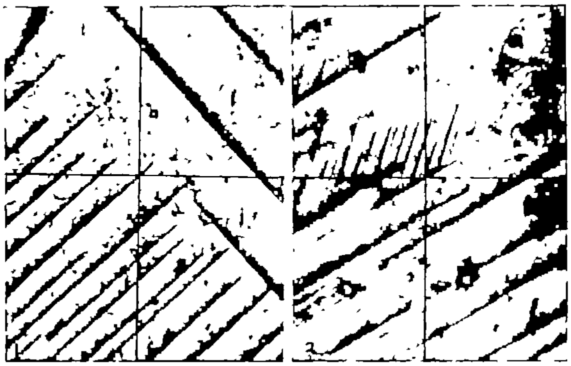
Twinning Structure in Crystals of Tungsten Trioxide

ɩ MICROSCOPIC examination of crystals of tungsten ɔxide (WO_3) has revealed a type of twinning very ıilar to the domain patterns characteristic of the roelectric (tetragonal) phase of barium titanate ıTiO$_3$). This similarity is significant in view of ı reported ferroelectric behaviour of tungsten ɔxide[1].

Ihe crystals, examined under the polarizing croscope, were grown by sublimation of the pours from a molten solution of tungsten trioxide solved in barium chloride, and contained in a ıtinum crucible. Their normal crystal habit was the form of very thin plates which varied in their nensions up to 5 mm. Most of them were almost nsparent and ranged in colour through various ıdes of pale green. Apart from the truly single ɣstals, many of the specimens showed a highly inned structure when viewed in a direction normal the plate surface. In polarized light, a series of rrow, parallel bands, in general, extended diagony across the crystal at an angle of approximately ' to the edges. From the effects of optical extinction th respect to the directions of vibration of the larized light, it was determined that the unit cell es of one domain are perpendicular to those of neighbour. These conclusions agree essentially th the observations of Ueda and Ichinokawa[2]. In dition to the fact that the cell axes, lying in the ıne of the crystal, differ only slightly from each ıer in length, this appears to be a prerequisite for ɘ formation of this domain pattern which is aracteristic of the ferroelectric phase in general. tetragonal barium titanate[3], the *a* and *c* axes of the ıt cell differ by approximately 1 per cent only. In ɘ analogous case of tungsten trioxide, the *a* and ıxes, which lie in the plane of the crystal plates, ıve a difference of less than 3 per cent[4]; the much orter *c*-axis is perpendicular to this plane. The mmetry of tungsten trioxide has been given as clinic[4] because of the slight distortion of the interial angles from 90°. However, for purposes of ıcussion, the crystal may be described in terms of pseudo-orthorhombic symmetry[3] with a twinning ıne {110}.

The boundary between contiguous domains appears tically as a fine dark line. This may be due either distorted unit cells at the junction, or to an actual smatching between the respective lattices. The n-uniform optical extinction which often occurs at ɘ boundaries would seem to indicate that these ɡions are in a highly strained state. This is especially vious in the wedge-shaped domains, or those which ve been formed by the convergence of their boundɣ planes within the crystal (Fig. 1). The banded main pattern presumably results from the relief internal strains developed during the growth of ɘ crystal, the wedge domains merely representing arrested or partial twin development.

On the larger specimens, twinning on a broader ıle was commonly observed, whereby the crystal divided into areas or distinct groups of line patterns iented at right angles to each other. From the companying photographs it can be seen that the ıdge domains exhibit a wide variation in width, d many of them have bifurcated ends. In Fig. 2 ıall branch domains can be seen developing from ɘ larger ones at an approximate angle of 45°, that parallel to the crystal edges. It is significant that this 'feather' structure appears to develop on one side only of the boundary. All these peculiarities may be assumed to be the result of internal strain.



Domain structure of tungsten trioxide crystals. × 200.
(1) Wedge domains showing the dark areas caused by internal strain. (2) Feather-like development of the domains

A more detailed explanation of some of the structural peculiarities of tungsten trioxide will be reported later.

Occurrence of Small-angle X-Ray Diffraction Maxima in some Artificial Cellulose Fibres

DIFFRACTION at small angles in cellulose fibres and rayon has been investigated by several workers[1]. Generally, a diffuse scattering increasing towards the primary beam has been observed on the equator of the fibre diagrams, with no distinct maxima characteristic of long spacings.

In fibres from highly oriented polyamides and from some other synthetic polymers, such as 'Terylene' and polythene, maxima at small angles have been observed on the meridian of the fibre diagram and have been related tentatively to a periodicity in the length and arrangement of the crystalline and non-crystalline regions in the direction of the fibre axis[2]. In well-oriented cellulose fibres no meridional maxima have been reported so far.

In an investigation on the small-angle scattering of various types of artificial cellulose fibres, exposed in the air-dry as well as in the water-swollen condition, we have found that some specimens in the water-wet state do show a distinct, though rather broad, equatorial maximum at small angles.

The exposures were made in a vacuum camera constructed by Backers in the Laboratory of Technical Physics of the Technical University, Delft, under the direction of Prof. H. B. Dorgelo and afterwards improved by Daams. This is essentially a three-slit arrangement with a metal wire for inter-

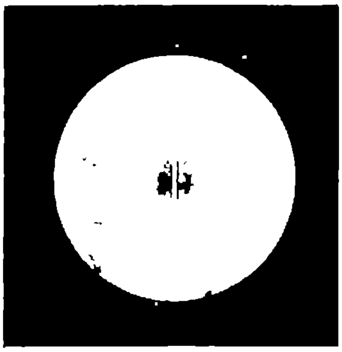

Fig. 1

ception of the primary beam[1]. The specimen-to-film distance is 77·6 mm. and the smallest observable diffraction angle 2 θ amounts to 0·0044 radians for copper radiation (corresponding to a Bragg spacing of more than 300 A.). In blank exposures no radiation whatever is detected on the film.

The fibres were exposed mounted parallel on a small rectangular wire frame, either in the air-dry condition or in the water-swollen state. In the latter case, the wire frame was enclosed in a small vessel provided with parallel windows made from very thin polymethylmethacrylate film and entirely filled with water. It was found to be essential to use radiation strictly monochromatized by reflexion from a crystal face.

Under these conditions, the photometer curves of the fibres exposed either dry or in the vessel filled with water are free from 'background' (that is, the blackening drops off to a zero value at some distance from the primary beam), and a blank exposure of the vessel with water does not produce any detectable blackening of the film in the small-angle region. (Exposure times were about 8 hr., using a powerful rotating-anode tube.) If nickel-filtered copper rad tion is used, there is always a considerable bac ground and, moreover, the small-angle maxima, present, can scarcely be detected. This reveals t occurrence of rather large amounts of parasi 'white' radiation of uncontrollable intensity even ve near the primary beam. Under these conditio blank exposures of the vessel also give rise to blacke ing of the film.

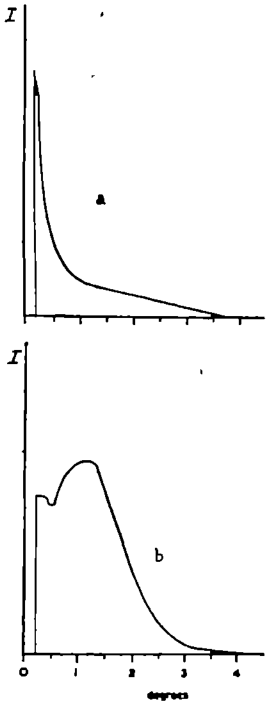

Fig. 2. Fibre *G*: (*a*) dry; (*b*) wet

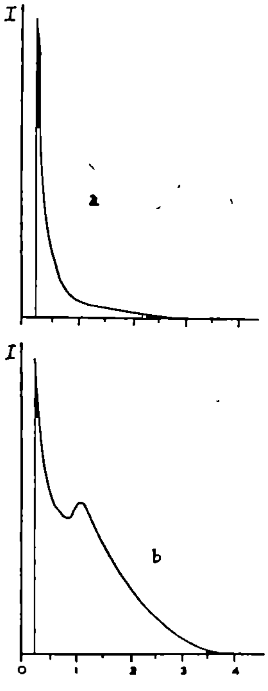

Fig. 3. 'Fortisan': (*a*) dry; (*b*) wet

Fig. 1 is the monochromatic exposure of Fibre in the wet state. In Figs. 2 and 3 are reproduced t photometer curves of monochromatic exposures Fibre *G* (sample by courtesy of Du Pont de Nemou Wilmington, Del.) and of 'Fortisan' (Celanese Cor in the air-dry state (*a*) and in the water-swoll state (*b*).

The positions of the maxima for the wet e posures correspond to Bragg spacings of 77 A. a 84 A., respectively. In the case of 'Fortisan' (Fig. there is clearly an additional continuous small-an scattering, increasing steeply towards the prima beam. In Fibre *G* (Fig. 2) there is no indication o similar continuous scattering.

We wish to leave open for future discussion t interpretation of these maxima. At all events th indicate some rather pronounced lateral periodic in the structure which is quite unexpected in artific fibres.

No maxima have shown up in other rayons so f investigated; but work is in progress to extend t range of specimens.

Reaction of Vitamin A Aldehyde with Plasma Albumin

Cohn[1] has shown that carotene and vitamin A a concentrated in fraction III-O of plasma, which a lipoprotein. It has been known for some time[2] th vitamin A can occur in water-soluble form in t urine of human beings in certain pathological co ditions. In such cases protein is invariably prese in the urine. It does not follow, however, that uri which contains protein can take up vitamin A wh added to it. Adequate explanation of this phenomen has not been forthcoming. The function of vitamin in the visual cycle has been very elegantly demo strated by Wald[3]. Recently, Morton[4] has shown th retinene, which is an important factor in the visu cycle, is vitamin A aldehyde, and he has also show how it can be prepared in the laboratory. It w therefore considered that attempts should be ma to prepare a water-soluble compound of vitamin with plasma protein and study its properties. T present preliminary communication summarizes t results obtained in this Institute.

Plasma albumin solution. This was prepared following Cohn's method[6], as follows. Bovine plasma was diluted with acetate buffer and brought to *p*H 5·9 at a temperature of – 3° to – 5° C. in a 'Thermos' flask, using a freezing mixture. To this was added, very slowly, a well-cooled solution of ethyl alcohol and acetate buffer (95 : 5) until the alcohol concentration of the mixture reached 40 per cent. Half an hour later, the mixture was filtered at a low temperature through Whatman filter paper No. 42. The clear filtrate, the protein content of which is entirely albumin[7], was diluted with phosphate buffer, *p*H 7·5, and an aliquot was dialysed in a rotary dialyser in a current of phosphate buffer (*p*H 7·5) in a cold room. Samples were taken at intervals and tested for the presence of ethyl alcohol by conversion to acetaldehyde, which was detected[8] by Schiff's reagent (max. absorption at 485 mμ). After dialysing for 36 hr., the albumin solution was found to be free from ethyl alcohol. After filtration and dilution, the absorption spectra of the albumin solution was taken (Fig. 1). It will be seen from the graph that the protein has an absorption peak at 280 mμ, which agrees with the value quoted in the literature[9].

Vitamin A aldehyde. Vitamin A acetate (1 million I.U./gm. in oil) was saponified with alcoholic potash, and vitamin A alcohol extracted with petroleum ether (40–60°). It was purified by chromatography, and vitamin A aldehyde prepared by Morton's method[5]. The absorption spectrum of the aldehyde was checked and found to have a peak at 369 mμ in petroleum ether. The solvent from an aliquot was removed *in vacuo.*

The residue was dissolved in ethyl alcohol and added to an aliquot of albumin solution. The mixture was shaken gently for about half an hour, and then dialysed in a rotary dialyser against phosphate buffer at *p*H 7·5, in the cold room. Tests for the presence of ethyl alcohol were carried out at intervals. After dialysing for 36 hr., the solution was found to be free from ethyl alcohol. It was then filtered and the absorption spectrum was taken after the necessary dilution. Two well-defined peaks, one at 280 mμ, characteristic of the protein used, and the other at 378 mμ due to the new chromophore, were found (Fig. 2).

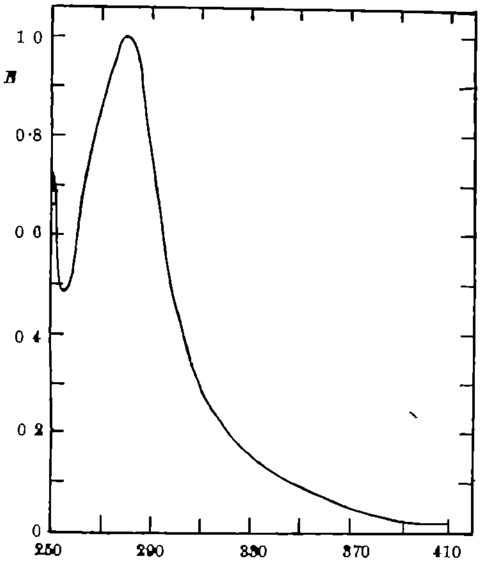

Fig. 1. Absorption spectra of plasma albumin in phosphate buffer (*p*H 7·5)

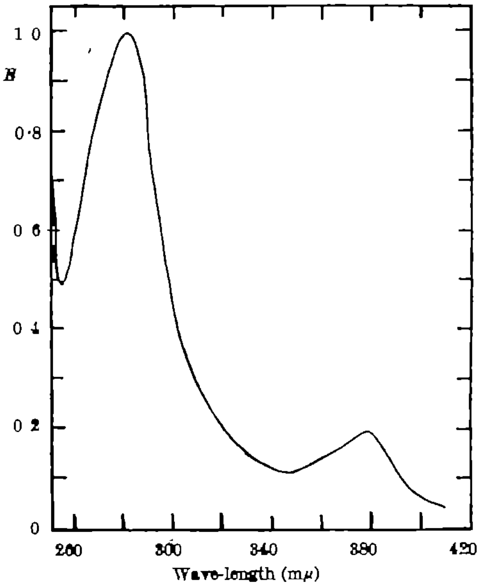

Fig 2. Absorption spectra of condensation product of plasma albumin and vitamin A aldehyde in phosphate buffer

The solution of the albumin–vitamin A aldehyde complex, suitably diluted for spectrophotometric study, gave the following analysis for albumin (micro-Kjeldahl method) and aldehyde : (i) protein content, 0·968 gm./100 c.c. of solution ; (ii) vitamin A aldehyde, 2·985 × 10^{-5} gm./100 c.c. of solution ; aldehyde content as percentage of protein content, 0·003.

In normal human plasma[10], 120–200 I.U. of vitamin A is associated with 6–8 gm. of protein ; that is, 1 gm. of protein is associated with approximately 6 μgm. of vitamin A. In the condensation product of protein and vitamin A aldehyde, 100 gm. of protein is associated with 3,000 μgm. of vitamin A aldehyde, which is roughly equivalent to five times the concentration of vitamin A alcohol present in normal blood.

The sample of vitamin A acetate used was kindly supplied by Messrs. Hoffmann LaRoche and Co., Basle. We thank the Indian Council of Medical Research for financial support, and also Col. C. K. Lakshmanan, director of this Institute, for encouragement in the work.

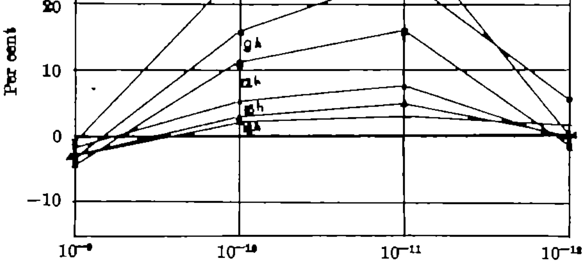
Sensitivity of Cress Roots to Indole-Acetic Acid

In 1939, Thimann[1] recorded in a discussion on the growth of roots: "The amount of auxin normally in these roots is not far from the optimum for their growth, so that further addition could be expected to accelerate growth only slightly". A marked increase in the root growth induced by indole-acetic acid should be obtained only if the supply of the acid in the root is less than the optimum; thus distinct increases have been produced with de-capitated roots depleted of their own source of indole-acetic acid[2]. However, experiments with *Lepidium sativum*[3], *Linum usitatissimum*[4] and *Artemisia absinthium*[5] have shown that it is possible to accelerate the root-growth of germinating seeds.

We found that the roots of germinating cress seeds have no constant growth-rate in spite of constant conditions. The measurements began 24 hr. after sowing. At intervals of 3 hr. the lengths of the roots were measured. At first the growth-rate increases to a maximum, then it decreases. The root of a cress seedling passes through three phases of growth: (1) at the beginning of germination a phase with a low growth-rate; (2) a phase of maximum growth-rate; (3) a phase of decreasing growth-rate. We were able to demonstrate by the determination of the indole-acetic acid content in roots of the second phase (5–6 mm. long) and of the third phase (20–25 mm. long) that the concentration of the acid in the short roots is about double that of the long roots. The amount of indole-acetic acid available to the roots determines the growth-rate. An acceleration of the growth-rate (about 15–20 per cent) was obtained with cress seedlings of the harvest 1944 and 1947, if the measurements were carried out in the third phase. The cress roots are sensitive to indole-acetic acid if their growth-rate is less than optimal.

The difference in duration of the first and second phases is evidently connected with the amount of indole-acetic acid in the seeds. We showed[6] that the amount of the acid contained in cress seeds of different years of harvest and of the same seedsman (H. Hild, Marbach, Germany) may be different: seeds of the year 1950 contain about ten times as much indole-acetic acid as seeds of the year 1947. The third phase is reached early with seeds of 1944 and 1947, late with seeds of 1949 and 1950.

The accompanying diagram shows the result of an experiment carried out with cress harvested in 1949, in which the effect of immersing the roots in indole-acetic acid for different lengths of time was determined[7]. The greatest increase occurred after a short treatment. As the roots approach their phase of maximum growth-rate, their sensitivity to the acid decreases progressively. If the acid is added to roots in the maximum growth-phase there is no response.



Lepidium sativum (harvest, 1949). Percentage increase (+) and inhibition (−) of the growth of roots in comparison with control (o–o– line) at various concentrations of indole-acetic acid and various treatment times

The roots of the cress seedlings which are susceptible to indole-acetic acid must be used either during the first or the third phases, but not during the period of maximum growth-rate (second phase). Even then the concentration of indole-acetic acid must be low, 10^{-10} gm./c.c. or less. Thus before the test is applied, it is necessary to determine the growth-curve of the available seeds.

It is believed that the causes of the low growth-rates in the first and third phases are different. In the first phase, the supply of indole-acetic acid is insufficient, because there is a delay while the reserves in the seeds gradually become available. These processes of activation are very uncertain, and it is rather difficult to bring them under control. Therefore, the results show great variability. In addition, the errors involved in measuring small increments (1–3 mm.) are greater. A real deficiency of indole-acetic acid occurs during the third phase because the reserves in the seeds run low. The seedlings are in the dark, and the normal supply is not established. The response to indole-acetic acid is very uniform, and the measurement of the larger increases (17–22 mm.) can be done more exactly.

Isolation of a Carbamido Acid from Autolysed Yeast

Samples of baker's yeast that have undergone autolysis in presence of toluene or chloroform give an intense red colour reaction when boiled with diacetyl in hydrochloric acid, which is characteristic of compounds of the type[1] $—CH_2—NH—CO—NH_2$. Of the natural urea derivatives at present known, citrulline is the only one that gives a red carbamido diacetyl reaction; urea, itself, gives a yellow colour; allantoin and allantoic acid give varying shades of orange-pink, probably due to urea liberated under the conditions of the test; cyclic ureides do not react chromatically. Hence, it was assumed at first that the yeast reaction was due to citrulline, originally present as a unit, or arising from arginine by desimidation.

With the object of identifying the chromogen, the autolysate obtained from 6 lb. of baker's yeast was filtered, diluted and subjected to displacement chromatography on 'Zeo-Karb 215'. The progress of the operation was followed by means of the diacetyl reaction, and the carbamido-rich portion of e effluent was collected and treated with copper rbonate. After recrystallization, a series of copper omplexes was obtained, from which the most bundant fraction was selected for investigation. It iffered completely in solubility and appearance from e known citrulline copper compounds. After reoval of the copper, the carbamido derivative was olated by recrystallization from water, and was btained as an ash-free, almost colourless microrystalline powder, the melting point of which reained constant at 238–239° decomp., after three ecrystallizations. The yield was approximately 00 mgm., from 6 lb. of yeast. Analysis: C, 44·1; I, 7·8; N, 15·0 per cent, corresponding to the ormula $C_7H_{14}O_4N_2$, which requires: C, 44·2; I, 7·4; N, 14·7 per cent.

Properties. The compound is very soluble in cold ater, forming an acid solution. It is almost insoluble n absolute ethanol and other neutral organic solvents. ormaldehyde titration gives a value corresponding o one active $—NH_2$ group per C_7 unit.

Function tests. (1) Carbamido diacetyl reaction, eep red; (2) *para*-dimethylaminobenzaldehyde in /1 sulphuric acid, bright yellow; (3) ninhydrin in ot, saturated boric acid, slow grey-violet (α-aminocids react much more rapidly and vividly under the ame conditions); (4) nitro-chromic test for primary nd secondary alcohol groups[2], slow; (5) lactose est for short-chain primary amines and ethanolmine[3], negative; (6) Millon reaction for phenols, egative; (7) aldehyde tests for indoles, negative; 8) pentacyanoferrate test for amidines and guanidxines[4], negative; (9) Sakaguchi reaction for subtituted guanidines, negative.

The investigation was supported by a grant to one f us (W. A. B.) from the Medical Research Council f Ireland, and is being continued.

Role of Progesterone in the Mating Behaviour of the Ewe

IT has been postulated[1–3] that a waning corpus uteum in the presence of a developing follicle is ecessary to produce œstrus in the ewe. One attempt o test this hypothesis by treating the anœstrous we with 2–5 mgm. progesterone before gonadotrophin njection yielded negative results[1]. Pretreatment vith 40–100 mgm. testosterone propionate has esulted in some 75 per cent incidence of œstrus ollowing pregnant mare serum injection[4]; but rates f conception are low. This low conception is due o either suppression of ovulation or to faulty ynchronization between ovulation and œstrus[3].

During December 1951, at which month ewes of British breed are in deep anœstrus in Australia, experinents were carried out on the Werribee State Research Farm near Melbourne, with the object of determning the role of progesterone in inducing mating ehaviour. In the first trial, four groups, each of seven mature Suffolk ewes, were treated with 1,000 I.U. pregnant mare serum subcutaneously in saline, alone or in combination with 35 mgm. progesterone subcutaneously in oil. They were sacrificed at appropriate intervals after treatment and, in those ewes served, the Fallopian tubes were washed out in the search for ova. Treatments were as follows: (1) 1,000 I.U. pregnant mare serum alone; (2) 1,000 I.U. pregnant mare serum + 35 mgm. progesterone simultaneously; (3) 1,000 I.U. pregnant mare serum 24 hr. after 35 mgm. progesterone; (4) 1,000 I.U. pregnant mare serum 48 hr. after 35 mgm. progesterone. Results are shown in the accompanying table.

Treatment No.	No. of ewes	No. of ewes ovulating	No. of ewes in œstrus	No. of ewes yielding fertile ova
1	7	4	–	–
2	7	7	–	–
3	7	7	–	–
4	7	7	3	2

No significance is attached to three ewes failing to ovulate in group 1. All three had extremely small ovaries containing only rudimentary follicles. It is considered significant, particularly in view of subsequent work, that œstrus was observed in three ewes of group 4, but not in any other group. Œstrus and ovulation occurred 2, 3 and 5 days after injection of pregnant mare serum. It is also significant that fertile ova were recovered from two of the three ewes coming into œstrus. No ovum was recovered from the third ewe. None showed any evidence of a spontaneous corpus luteum which could have reacted with the injected gonadotrophin, so heat and ovulation are attributed to a progesterone–gonadotrophin synergism. The response obtained has approached physiological normality more closely than the previously reported testosterone–gonadotrophin synergism, and has yielded fertilized ova after a single injection of pregnant mare serum.

Two subsequent trials, in which progesterone was administered in 50 per cent ethanol both subcutaneously and intravenously up to 48 hr. before the injection of pregnant mare serum, yielded negative results, the ewes ovulating without œstrus. This indicates that pretreatment some time before an injection of pregnant mare serum, and slow absorption of the progesterone, are necessary for induction of œstrus; treatment earlier than 48 hr. before injection is indicated.

It is suggested that the action of progesterone is to develop receptors in organs such as the uterus, for example, these receptors responding to subsequent œstrogen stimulation resulting in œstrous behaviour. This view receives some support from the observation that tonic uterine contractions, normally present at œstrus, are absent at ovulations induced by gonadotrophin which are unaccompanied by œstrus[5]. Since œstrus with ovulation was observed as early as 48 hr. after administration of pregnant mare serum, and since progesterone did not appear to act like testosterone and inhibit or markedly delay ovulation, this would appear to preclude the suggestion[3] that progesterone acts simply by delaying ovulation.

Further work is planned for the next anœstrous season. Grateful acknowledgment is made to the staff of the Werribee State Research Farm, and in particular to Mr. Bruce McGregor, for their cooperation. Progesterone was kindly given by the

British Drug Houses, Ltd., and serum gonadotrophin by Boots Pure Drug Co., Ltd., to whom thanks are due.

Synthesis of Diphosphopyridine Nucleotide by Cell Nuclei isolated in Aqueous Media

IT has recently been demonstrated that reasonably homogeneous preparations of cell nuclei can be isolated in good yield from rat or mouse liver[1]. By means of centrifugal fractionation of liver homogenates prepared in an aqueous medium (0·25 *M* sucrose – 0·0018 *M* calcium chloride), it has been possible to obtain 70–90 per cent of the nuclei with a minimum of cytological alteration in preparations containing by direct count less than 1 per cent of the intact cells of the tissue and less than 0·5 per cent of the free mitochondria of the homogenates.

The value of this method in cytochemical studies obviously depends on the permeability of the nuclear membrane. In this respect, Allfrey *et al.*[2,3] have contended that cell nuclei isolated in aqueous media are ill-adapted for studies of enzyme localization, primarily because extraction of water-soluble proteins is said to occur. These investigators have described a tedious method for the isolation of nuclei in organic solvents, utilizing desiccated tissue as the starting material. We are of opinion that it is unnecessary to resort to non-aqueous media.

Evidence for the integrity of nuclei isolated in aqueous media (other than their relatively high protein content[1]) has arisen from a study of the distribution in mouse liver homogenates of the enzyme catalysing the synthesis of diphosphopyridine nucleotide from nicotinamide mononucleotide and adenosine triphosphate. In a number of experiments, 69–101 per cent of the diphosphopyridine nucleotide-synthesizing activity of the homogenates was recovered in the nuclear fraction. Approximately 3 per cent of the original activity was found in the mitochondrial fraction, and the remainder was present in a fraction containing submicroscopic particles and the soluble material of the cytoplasm. The specific activity of the isolated nuclei (2·0–2·4 micromoles of diphosphopyridine nucleotide formed per hour per milligram of total nitrogen at 38°) was greater than that of the homogenates by a factor of 5–6. The higher recoveries of enzyme in the nuclear fraction (an average of 92 per cent in four consecutive experiments) were obtained when a step known to cause nuclear damage was eliminated from the fractionation procedure, and it seems entirely possible that the small amount of activity found under these conditions in the cytoplasmic fractions may have been the result of nuclear damage during the initial homogenization of the liver. When the isolated nuclei were disrupted by exposure to sonic oscillations[4] for 10 min. at 2°, approximately 85 per cent of the activity remained unsedimented after centrifugation for 30 min. at 130,000 times gravity.

The synthesis of diphosphopyridine nucleotide by liver cell nuclei is of interest for several reasons. Th enzyme involved is a water-soluble protein that ha been purified to a considerable extent[5]. Thus, a least in this one instance, the claim of Allfrey *et a* with respect to the extraction of proteins from nucle by aqueous media is not supported. Furthermore, s far as we are aware, the present finding comprise the first example of the clear-cut localization of a enzyme in isolated nuclei. Finally, since a number o diphosphopyridine nucleotide-linked dehydrogenase have been recovered largely in the cytoplasmi fractions[6], the synthesis of the coenzyme by isolated nuclei represents an example of an apparent biochemical interaction between nucleus and cytoplasm

A more detailed description of the present work will be published elsewhere.

Behaviour of Fertilized Rabbit Eggs exposed to Glycerol and to Low Temperatures

MAMMALIAN spermatozoa, red blood-cells and ovarian tissue suspended in glycerol-containing media have been cooled to, and maintained for long periods at – 79° C. or – 190° C., and have resumed functional activity when thawed and inseminated transfused or grafted[1–4]. The present study of the reaction of fertilized rabbit eggs to glycerol and to low temperatures was undertaken to extend these researches to a different and more active type of cell and one which has not hitherto been found to survive exposure to low temperatures[5,6].

Fertilized eggs were recovered from the Fallopian tubes of rabbits 18–25 hr. after injection of chorionic gonadotrophin and artificial insemination. In preliminary experiments they were transferred to homologous serum containing 15 per cent glycerol at + 20° C. Under these conditions the eggs shrank down within the zona pellucida, presumably because of the hypertonicity of the medium. At + 5° C. the shrinkage was greater. When transferred successively to 2·5, 3·75, 5 and 7·5 per cent glycerol in serum at + 20° C., they contracted and re-expanded during one hour at each stage, suggesting that glycerol was penetrating into the eggs. In the course of treatment with 10 and 15 per cent glycerol, however, they shrank irreversibly, and when incubated in 15 per cent glycerol for 18 hr. or cultivated in serum after removal of glycerol by gradual stages or by washing, they degenerated. By contrast, fertilized rabbit eggs treated in successive 10-min. stages with 2·5 3·75, 5, 7·5, 10 and 15 per cent glycerol in serum at + 37° C. contracted only slightly and quickly re-expanded, suggesting that the ova were more permeable to glycerol at + 37° C. than at + 20° C. The glycerol was then removed at + 37° C. by eversing these stages, and some of the eggs began o divide in 3·75 and 2·5 per cent glycerol and the emainder soon after transfer to serum. The majority continued development *in vitro* for a further 24–48 hr. and became morulæ, showing that brief exposure to glycerol at body temperature has not, apparently, any adverse effect on the egg. The necessity for reatment with warm glycerol is of particular interest, ince most cells and tissues so far tested have tolerated glycerol well at room temperature, whereas the best results with bull spermatozoa were obtained[1] by prolonged soaking in glycerol at + 5° C.

Eggs treated with glycerol at + 37° C. were then ooled to, and kept at, different temperatures. The glycerol was removed after rewarming to + 37° C. and before cultivation. Of different batches superooled in various ways to – 15° C., 75 per cent were viable after one hour, 67 per cent after one day, 40 per cent after two days and 69 per cent after hree days at that temperature. By contrast, only 0–30 per cent of eggs were viable after an exposure of an hour to – 17° or – 20° C., or after four to even days at – 15° C., when the medium had olidified. It seemed, therefore, that 15 per cent glycerol in serum at – 15° C. gave results little different from plain serum[7] at + 10° C. and was unpromising for long-term study of fertilized rabbit eggs.

Other batches of eggs in 10, 15 or 20 per cent glycerol in serum were cooled at different rates to – 79°, – 160° and – 190° C., and left for periods varying from 10 min. to two days before thawing at + 40° C. Immediately after thawing, all the eggs rozen rapidly by the method of Luyet[8,9] were uptured, misshapen or degenerate. By contrast, a high proportion of eggs cooled relatively slowly by the methods used for sperm and ovarian tissue[1,4] were, on thawing, normal in appearance. After emoval of glycerol, however, the majority degenerated. So far, out of a total of 556 eggs slowly cooled either to – 79° or to – 190° C., only six unicellular eggs, each from a different treatment group, have divided normally in culture. Three of them divided nto two blastomeres, two reached the 4-celled stage, and one became 6-celled. Phase-contrast microscopy revealed no abnormalities of cleavage or n their structure.

This result is sufficient to show that exposure to ow temperatures is not necessarily lethal to mammalan ova, even during the highly active and unstable phase between syngamy and segmentation. Further experimentation, especially on the rate of freezing and thawing and on the use of glycerol, should make t possible to increase greatly the rate of survival and elucidate further the processes involved in the reezing and thawing of living cells.

Origins of the Volatile Fatty Acids in the Rumen

MEMBERS of the saturated fatty acid series C_1–C_7 are formed during the fermentation of wheaten hay or lucerne hay in the rumen of the sheep[1,2], and these acids, together with the methane and carbon dioxide also produced, account for a large part of the carbon of the digestible fraction of the fodder. Cellulose and hemicellulose form the bulk of this digestible material, and protein contributes to it to a lesser degree; it is therefore important to determine the nature of the products formed from each of these main components of the substrate. The fermentation of any particular compound may depend on the activities of a number of different organisms, and the detailed course of the degradation will present a difficult problem, involving, finally, a study of these organisms in pure culture. Its elucidation will, however, best be pursued in the light of knowledge of the products formed from the substance by the mixed culture of rumen organisms.

By means of the methods and techniques previously developed for the study of the fermentation of the natural fodders[3], we have examined the fatty acids produced *in vitro* from cellulose and hemicellulose when fermented alone, or together, or in the presence of wheaten hay. The products were compared with those formed from wheaten hay alone. We have also compared the products formed from a mixture of cellulose and hemicellulose with those produced from the same mixture in the presence of a small quantity of protein prepared from wheaten hay; and finally, we have fermented cellulose in the presence of various amounts of casein. The results of some of these experiments are presented in Tables 1 and 2.

It is clear that the fermentation of both cellulose and hemicellulose gave rise to approximately equal parts of acetic and propionic acids, together with a very small proportion of butyric acid, and that the presence of protein led to the formation of greater proportions of the latter acid. The formation of acetic and propionic acids from cellulose has already been described by Elsden[6] and by Marston[7]; but the production of these acids in approximately the

Table 1. FERMENTATION OF WHEATEN HAY AND SOME OF ITS SEPARATE CONSTITUENTS

Substrate	Composition of acid produced		
	% Acetic	% Propionic	% Butyric (*e*)
Wheaten hay (*a*)	54	26	20
Cellulose (*b*)	48	46	6
Hemicellulose (*c*)	46	45	9
Cellulose, hemicellulose	46	46	8
Cellulose, hemicellulose protein (4%) (*d*)	52	35	13

(*a*) Different samples of wheaten hay may show marked differences in the proportions of acids formed from them. (*b*) Cellulose prepared from wheaten hay by the method of Norman and Jenkins (ref. 4). (*c*) Hemicellulose prepared from wheaten hay by the method of McIlroy, Holmes and Mauger (ref. 5). (*d*) Protein prepared from wheaten hay. (*e*) Butyric acid includes any higher acids of the series which may have been present.

Table 2. INFLUENCE OF CASEIN ON CELLULOSE FERMENTATION

Substrate	Composition of acid produced		
	% Acetic	% Propionic	% Butyric
Cellulose (*a*)	51	42	7
Cellulose, casein (5%)	47	31	22
Cellulose, casein (10%)	44	31	27
Cellulose, casein (20%)	45	25	30

(*a*) Finely ground filter paper.

same proportions from the two constitutionally different substrates, cellulose and hemicellulose, was unexpected, and is particularly interesting from the point of view of the intermediate products involved in each case. Confirmation of these findings with other samples of hemicellulose or with pure pentosans is needed.

Whether or not the degradation of separated cellulose or hemicellulose follows the same pathways as the degradation of the substances within the whole plant structure cannot finally be decided. It is possible that the course of fermentation of a particular substance may be altered by any considerable change in the nature of the substrate as a whole. It is therefore true that some doubt must always remain in the interpretation of these results. In this regard it may be mentioned that the acid formed from a mixture of cellulose (or hemicellulose) with wheaten hay was intermediate in composition between that formed from cellulose (or hemicellulose) on one hand, and that from wheaten hay on the other.

Since only a small proportion of butyric acid is produced from either cellulose or hemicellulose, some other origin for this acid in the fermentation of wheaten hay is implied. It has already been shown that part of the butyric acid in the rumen is synthesized from acetic acid[1], and it is possible that this accounts for the small quantities formed in the cellulose and hemicellulose fermentations. The present experiments suggest that another part of the butyric acid may be derived from the protein fraction of the fodder.

Stimulating Effect of Amino-Acids on the Survival at 37° C. of *Trypanosoma rhodesiense* in a Serum-free Synthetic Medium

Blood (whole, or as plasma, serum, erythrocytes or laked erythrocyte solution) is an essential component of culture media for many pathogenic Protozoa. The essential nutritive components in rabbit, ox, sheep, horse or pig serum required to maintain pathogenic African trypanosomes in culture at 37° C. in the trypanosoma form have not been investigated extensively since the discovery by Yorke, Adams and Murgatroyd[1] that *T. equiperdum*, *T. rhodesiense* and *T. gambiense* could be maintained under these conditions in an actively motile state and in undiminished numbers for 24 hr.

Suspensions of *T. rhodesiense* were prepared from infected mice and set up according to Yorke's basic technique. Marked variability in culture survival was traced to the serum content of the parasite inoculum. The importance of this factor is shown i experiments using washed parasites (Table 1).

Table 1

Medium*	Serum concentration (v/v)	Survival time (hr.)
BR	6·3 per cent	>6 <23
BR	1·6 ,,	<1
BRG	0·1 ,,	4

* For compositions of media, see later.
† Survival times refer to period during which parasites are active motile and in undiminished numbers.

The more marked effect in the presence of glucos suggests coenzyme activity, and glucose dehydr genase activity at 25° C. of washed *T. rhodesiens* suspensions (M/60,000 methylene blue, M/100 glucos in isotonic phosphate buffered Ringer solution pH 7·4 reaction in Thunberg tubes followed photometricall is, in fact, stimulated by serum even in concentration as low as 0·0004 per cent. Suspensions washed twic in *BR* gave reproducible survival times under standar conditions and were used throughout.

Effect of glucose, trace metal salts and ten 'biologicall essential' amino-acids on T. rhodesiense *survival i sterile isotonic phosphate-Ringer* (*BR*) pH 7·4. Th composition of these solutions was as follows: ('Pyrex distilled water and A.R. grade salts throughout; fin concentrations in μgm./ml.).

BR: NaCl, 4,000; KCl, 100; $CaCl_2$, 100; $MgCl_2.6H_2O$, 25
$NaHCO_3$, 1,000; KH_2PO_4, 1,800; Na_2HPO_4 (anhydr.), 7,57
G: Glucose, 2,000.
M: $FeCl_3.6H_2O$, 0·15, $CuSO_4.5H_2O$, 0·12; $MnSO_4.4H_2O$, 0·01
$NiSO_4$, 0·013; $CoSO_4.7H_2O$, 0·024; $ZnSO_4.7H_2O$, 22.
A: DL-Threonine, 126; L-valine, 63; L-leucine, 158; L-iso-leucin 53; L-arginine HCl, 79; L-lysine HCl, 79; DL-methionin 126, L-phenylalanine, 26; L-histidine, 26; L-tryptophan 21; (total amino-acid concentration, 757 μgm./ml.).

All solutions throughout were sterile and the usu precautions were taken with heat-labile component Effects of these blocks of constituents on surviv are shown in Table 2.

Table 2

Medium block	No. of separate suspensions	No. of individual cultures	Survival time in undiminished numbers (hr.)*
BR	2	6	0·5
BRG	9	11	1
BRGM	48	91	1
BRGMA	38	58	4·5

* Survival times refer to period during which parasites are active motile and in undiminished numbers.

Of the 91 cultures with *BRGM*, 83 survived 1 h and 8 survived 1·5 hr., and of the 58 cultures wit *BRGMA*, 19 survived 4·5 hr.; 9, 5 hr.; 9, 3·5 hr. 7, 4 hr.; 7, 6 hr.; 4, 3 hr.; 2, 5·5 hr. and 1, 7 hr.

An effect quantitatively similar to that of th amino-acid mixture was produced by a vitamin-fre casein hydrolysate (Ashe) at a level of 500 μgm./m Survival was found to be proportional to amino-ac concentration at levels down to 48 μgm./ml., and t casein hydrolysate concentration at levels down t 15 μgm./ml.

Substances without effect on survival on addition *BRGMA*. *Added individually:* DL-cysteine, glut thione, L-cystine, L-tyrosine, L-serine, glycine, D aspartic acid, L-glutamic acid, creatine; ammoniu chloride, urea; citrate, fumarate, malate, succinate xanthine, hypoxanthine, uracil, thymine, guanine an guanidine.

Added together or in a variety of combinations ascorbic acid, aneurin, riboflavin, biotin, pant thenate, pyridoxine, nicotinic acid, nicotinamid inositol, choline, folic acid, p-aminobenzoic acid.

Substances with significant effect (1–2 *hr. prolonga-on*) *on survival on addition to BRGMA*. Adenine, denosine, yeast nucleic acid (commercial), thymus ucleic acid (commercial), adenine and ribose and icotinamide, adenosine and nicotinamide, adenosine nd nicotinic acid.

Rabbit serum ultrafiltered through transparent ellulose (British Sidac, Ltd.; pore size 7–30 A.) and resumably protein-free (biuret negative) has a more arked but, compared with an equal volume of erum, incomplete ability to promote parasite survival 5 hr. with *BR*, *BRG*, *BRGM*, and about 8 hr. with *RGMA*). A comparable effect is produced by 0·2 per ent 'Difco' bacto-peptone.

Effect of gaseous environment. All the above xperiments were carried out in air. Carbon dioxide-ree air, 100 per cent oxygen and 100 per cent itrogen were found to be toxic for cultures in *RGMA* containing water-soluble vitamins, adenine nd ribose. Survival in this medium was enhanced y incorporation of 5 per cent carbon dioxide, and arkedly enhanced by the mixture 5·6 per cent arbon dioxide, 7·8 per cent oxygen, 86·6 per cent itrogen.

This work was carried out in the Department of hemotherapy, Liverpool School of Tropical Medicine, uring the tenure of a May and Baker Research ellowship by one of us (J. W.) and of a Medical esearch Council grant by the other (I. M. R.).

Chemical Composition of Mammalian Sperm

Mammalian sperm have been reported by various orkers to contain no nucleoprotamine or nucleo-istone extractable by the usual means (with water r neutral salt solutions)[1]. This has been confirmed n the case of the bull, man, dog, boar and ram, ut basic protein and nucleic acid, having solubility roperties quite different from the usual, have been xtracted from the isolated heads of these cells.

A lipoprotein has also been extracted from the solated heads of the above-mentioned sperm. In the ase of bull sperm, this complex contains slightly ore than 25 per cent lipid, which includes phospho-ipid and cholesterol. The lipoprotein of human perm was found to contain only one component lectrophoretically at pH 8·2.

The sperm heads can be fractionated, by a simple rocedure, into three parts which make up almost all he total substance of the heads. The lipoprotein is btained by extracting with a 0·14 M sodium chlor-de solution adjusted to pH 9 with sodium hydroxide, nd the basic protein and nucleic acid by extracting ith more strongly alkaline solutions. The lipoprotein is precipitated from solution at about pH 5·6, the basic protein in the region of pH 11 and the nucleic acid at about pH 2.

Details of this work will be published elsewhere.

This investigation was supported in part by a research grant, C-1327, from the National Cancer Institute, of the National Institutes of Health, U.S. Public Health Service.

Totem Poles and Blood Groups

In reviewing a book on totem poles in the Pacific coast region of British Columbia, Dr. G. H. S. Bushnell[1] accepts the suggestion that "the north-west coastal tribes may themselves have come over from Siberia within the preceding few centuries". This conclusion, which was formerly held, is negatived not only by the fact that the Eskimos have long occupied the whole of the Alaskan coast, but also by the blood groups of the Indians in question.

To test this very question, three hundred of the coastal Indians were blood-grouped many years ago[2]. Although much mixed with Europeans, they showed only 12·7 per cent A, and two B individuals, one of whom was Negroid. If they were a late wave from Siberia, they should have had a high frequency of B, like all the Mongoloid peoples of Asia. Ride and Furuhata afterwards tested 203 more Indians from the same areas with similar results. The high percentage of the O blood group (75–86 per cent) is thus quite incompatible with a late Mongoloid origin of the British Columbia Indian tribes. They must apparently be derived from an earlier stratum of Asiatic population, which is represented, at least in part, by some Tibetans and by certain remnant tribes on Formosa. This subject has also been discussed elsewhere[3].

In quoting the suggestion to which Prof. Ruggles Gates takes exception, I did not mean to give the impression that I either accepted or denied it, since I did not feel competent to express an opinion about it.

The first objection, based on the distribution of the Eskimos, does not seem to me to exclude the possibility of a migration by sea. On the other hand, speaking as a layman in matters of genetics, I can only say that the evidence of blood groups seems conclusive, and I am grateful to Prof. Ruggles Gates for directing attention to it.

FORTHCOMING EVENT

Wednesday, September 3—Wednesday, September 10

BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE (at Queen's University, Belfast)—Annual Meeting

Wednesday, September 3

At 8 30 p.m.—Prof A. V Hill, F.R.S . "The Ethical Dilemma of Science" (Presidential Address).

Thursday, September 4

At 10 a.m —Prof. A. M Tyndall, F.R.S. · "Contributions to Experimental Physics from Britain" (Presidential Address, Section A)

At 10 a m —Prof. W. Wardlaw . "The Advancing Front of Chemistry" (Presidential Address, Section B)

At 10 a m —Prof. A D. Peacock · "Some Problems of Parthenogenesis" (Presidential Address, Section D).

At 10 a m —Prof. Meirion Thomas, F R S. · "The Anatomy of Metabolism in Higher Plants; Metabolic Processes and Partial Reactions" (Presidential Address, Section K).

At 12 noon.—Prof. P. E Vernon : "The Assessment of Personality" (Presidential Address, Section J).

At 12 noon.—Mr. J Pimlott · "The History of Afforestation in Northern Ireland" (Chairman's Address, Section K*).

At 2 p.m.—Mr. J. A. S. Standall . "Problems and Responsibilities" (Presidential Address, Conference of Delegates).

At 5 30 p m.—Dr. D. W. Bronk, F.R.S. . British-American Association Lecture

Friday, September 5

At 10 a m.—Prof. D T. Jack : "Full Employment in Retrospect" (Presidential Address Section F)

At 10 a.m.—Sir Ben Lockspeiser, F.R.S. . "Progress in Aeronautical Science and Engineering" (Presidential Address, Section G)

At 10 a.m.—Rev. Prof. E. O. James · "Archæology, Folk-lore and Sacred Tradition" (Presidential Address, Section H).

At 10 a m.—Mr A. L. Binns "Education of Africans in East and Central Africa" (Presidential Address, Section L).

At 10 a.m —Dr. N. C. Wright . "Britain's Food Supplies" (Presidential Address, Section M).

At 8 p.m.—Mr. A. C. Hartley · "Oil in Peace and War".

Sunday, September 7

At 8 p.m —Prof. A. Macbeath · "A Plea for Heretics".

Monday, September 8

At 10 a.m —Dr J. E Richey, F R.S.: "Some Aspects of Geological Research and their Practical Application" (Presidential Address, Section C).

At 10 a m.—Prof R. O. Buchanan "Aspects of Settlement in the Overseas Dominions" (Presidential Address, Section E.)

At 10 a.m.—Prof R. C. Garry : "Nervous Control of the Movements of the Alimentary Canal" (Presidential Address, Section I).

At 8 p.m —Sir William Slater · "Science and an Expanding Agriculture".

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned ·

AREA CHIEF CHEMIST at the Central and Research Laboratories, Nechells, Birmingham—The Industrial Relations Officer, West Midlands Gas Board, 6 Augustus Road, Birmingham 15 (September 0).

LECTURER IN ELECTRICAL ENGINEERING at the Rutherford College of Technology—The Director of Education, City Education Office, Northumberland Road, Newcastle-upon-Tyne 1 (September 0).

PHYSIOLOGIST (with a good honours degree in physiology and research experience, preferably involving the perfusion of isolated organs) for research on the bovine udder—The Secretary, National Institute for Research in Dairying, Shinfield, Reading, quoting Ref 52/11 (September 6).

SENIOR LECTURER or LECTURER IN CROP PRODUCTION at the University College of the Gold Coast—The Secretary, Inter-University Council for Higher Education in the Colonies, 1 Gordon Square, London, W.C 1 (September 6).

ENGINEER-IN-CHARGE OF GENERAL AND CO-ORDINATION SECTION (with an honours degree in engineering or equivalent, and wide experience of large power station plant practice) (Ref. AE/279), and an ENGINEER-IN-CHARGE OF BOILER SECTION (with qualifications not below A.M I.Mech E. standard, and a wide knowledge of boiler plant design for large power stations) (Ref AE/280) . in the Generation (Plant Design) Sub-branch at Operational Headquarters in London—The Director of Establishments, British Electricity Authority, British Electricity House, Great Portland Street, London, W.1, quoting the appropriate Ref. No. (September 8).

SENIOR LECTURER IN METALLURGICAL ANALYSIS, to Honours B Sc. (Metallurgy) standard, and a LECTURER IN CHEMISTRY—The Registrar, College of Technology, Suffolk Street, Birmingham 1 (September 8)

ASSISTANT LECTURER IN THE DEPARTMENT OF AGRICULTURE (Crop Husbandry)—The Registrar, University College of Wales, Aberystwyth (September 13).

ASSISTANT LECTURER or LECTURER IN CHEMISTRY (with special qualifications in inorganic or analytical chemistry)—The Registrar, The University, Sheffield (September 13).

VICE-PRINCIPAL AND HEAD OF THE UNIVERSITY DEPARTMENT, Fourah Bay College, Sierra Leone (University of Durham)—The Secretary, Advisory Committee on Colonial Colleges, 15 Victoria Street, London, S.W.1 (September 13).

FISHERIES SUPERINTENDENT AND OFFICER FOR THE PREVENTION OF POLLUTION—The Acting Clerk to the Wye River Board, 20 East Street, Hereford (September 15).

RESEARCH ASSISTANT (with a good honours degree and some research experience) IN THE LUMINESCENCE LABORATORY of the Department of Physics—The Registrar, The University, Edgbaston, Birmingham 15 (September 15).

DEMONSTRATOR IN GEOGRAPHY—The Secretary, The University 38 North Bailey, Durham (September 20).

SENIOR RESEARCH OFFICER (Plant Pathologist) IN THE MICROBIOLOGY SECTION, Division of Plant Industry, Canberra, to undertak plant disease investigations and in particular to study fundamenta aspects of host pathogen relationships and the mechanism of resistanc to disease—The Chief Scientific Liaison Officer, Australian Scientifi Liaison Office, Africa House, Kingsway, London, W.C.2, quotin No 3948 (September 27)

ASSISTANT LECTURER IN THE PUBLIC HEALTH ENGINEERING DIVISIO of the Department of Civil Engineering—The Head of the Departmen of Civil Engineering, Imperial College of Science and Technology South Kensington, London, S.W.7 (September 29).

PHYSICAL CHEMIST or PHYSICIST for a research post under th Professor of Chemistry, to investigate the chemical composition o the stratosphere—The Secretary, The University, 38 North Bailey Durham (September 30)

STATISTICIAN (a qualification in statistics, not necessarily medica or in mathematics with experience of statistical work, is essential to work on the problems of human reproductive performance in Aberdeen—Prof. Dugald Baird, Department of Midwifery, University o Aberdeen, Forresterhill, Aberdeen (October 1)

ASSISTANT or ASSOCIATE PROFESSOR OF ANATOMY (preferably wit experience in gross anatomy or neuro-anatomy)—The Dean, Facult of Medicine, Dalhousie University, Halifax, Nova Scotia, Canada.

ASSISTANT LECTURER IN CHEMISTRY, and a RESEARCH ASSISTAN IN METALLURGY—The Secretary, Northampton Polytechnic, St. Joh Street, London, E C.1.

CHEMISTS AND PHYSICISTS (Senior Scientific Officer or Scientifi Officer grade) for work on combustion processes in flames, at th Royal Aircraft Establishment, Farnborough—The Ministry of Labou and National Service, Technical and Scientific Register (K), Almac House, 26 King Street, London, S.W 1, quoting F.557/52A.

DESIGN ENGINEERS at the Atomic Energy Research Establishment Harwell, for work on design of nuclear reactors and their components to take part in design work either as individual designers or in charg of small teams engaged in development of nuclear power systems—The Ministry of Labour and National Service, Technical and Scientifi Register (K), Almack House, 26 King Street, London, S W.1, quotin C.513/52A.

EXPERIMENTAL OFFICER or ASSISTANT EXPERIMENTAL OFFICE (with chemical or biochemical experience) for enzyme research, and SENIOR ASSISTANT (Scientific) with experience in chemistry or biochemistry—The Secretary, Rowett Research Institute, Bucksburn Aberdeenshire

GRADUATE to assist in work on nutritional and toxicological problems—Prof. A. C. Frazer, Department of Pharmacology, The University, Birmingham.

GRADUATE RESEARCH ASSISTANTS (3) IN THE DEPARTMENT O CLINICAL CHEMISTRY, University of Edinburgh · for one post candidates should have a sound knowledge of zoology or comparative physiology and should be trained in histological techniques · for th other two posts training in biochemistry is required—Dr. C. P Stewart, Clinical Laboratory, Royal Infirmary, Edinburgh.

HEAD OF THE ENGINEERING GEOLOGY BRANCH (Executive Engineer Grade II) in the Scientific Services Division of the Snowy Mountain Hydro-Electric Authority Australia—The Engineer-in-Charge, Snowy Mountains Hydro-Electric Authority, 18 George Street, London, W.1

LECTURER, and RESEARCH ASSISTANTS (2), IN BIOLOGY (botan and zoology)—The Secretary, Royal Technical College, Glasgow.

PHYSICAL CHEMIST (with knowledge of the technique of electronics to assist in the development of an installation for the dating of organi remains by the use of radioactive carbon—Dr. H. Godwin, School o Botany, or Dr. A. G. Maddock, Department of Chemistry, The University, Cambridge.

PHYSICAL CHEMIST (Principal Scientific Officer grade) at th Ministry of Supply London headquarters, for the initiation and progressing of research and development work on rubbers for Servic purposes and advice to Service Departments on technical applicatio of rubber—The Ministry of Labour and National Service, Technica and Scientific Register (K), Almack House, 26 King Street, London S.W.1, quoting F.502/52A.

PHYSICISTS and PHYSICAL CHEMISTS (Experimental Officer grade at a Ministry of Supply establishment at Aldermaston—PHYSICA CHEMIST or PHYSICIST with interest, and preferably experience, i work on ceramic materials (Ref F.560/52A), and a PHYSICIST wit experience of X-ray diffraction (Ref A. 219/52A)—The Ministry o Labour and National Service, Technical and Scientific Register (K Almack House, 26 King Street, London, S.W.1, quoting the appropriate Ref. No.

RESEARCH WORKER with experience in X-ray crystallography, t assist with work concerned with the structures of nucleosides an nucleotides—Dr. W. Cochran, Cavendish Laboratory, Free Schoo Lane, Cambridge

SENIOR BIOCHEMIST (with an appropriate university science degre or the A R I.C., or an equivalent qualification, and wide experience o biochemical work, preferably in hospital laboratories)—The Secretar Derby No. 1 Hospital Management Committee, Babington Building Babington Lane, Derby.

SENIOR EXPERIMENTAL OFFICER at Ministry of Supply Londo headquarters, for duties concerned with research and development o aircraft textile materials in all forms (fabrics, cordages, ropes, etc and involving technical consultations with industry and researc organizations, placing and progressing of contracts and preparatio of specifications—The Ministry of Labour and National Servic Technical and Scientific Register (K), Almack House, 26 King Stree London, S.W.1, quoting F.561/52A

SENIOR PRINCIPAL SCIENTIFIC OFFICER at the Atomic Ener Research Establishment, Harwell, to take charge of mechanic engineering design work in nuclear reactor projects of considerabl magnitude—The Ministry of Labour and National Service, Technic and Scientific Register (K), Almack House, 26 King Street, Londo S.W.1, quoting C.498/52A.

UNIVERSITY GRADUATES IN ELECTRICAL ENGINEERING or in SCIENC Subjects (which must include experimental physics) as ASSISTAN ENGINEERS (temporary) in the Department of Posts and Telegraph Ireland—The Engineer-in-Chief, Leitrim House, Dublin.

THE INTEGRITY OF SCIENCE

PROF. A. V. HILL'S presidential address to the British Association (see p. 388) takes up as a challenge the concluding paragraph of his predecessor's address at Edinburgh. "It is clearly our duty as citizens to see that science is used for the benefit of mankind. For, of what use is science if man does not survive?" With those words as a text, Prof. Hill proceeds to discuss how far science has already contributed to human betterment, how far it has provided fresh problems, dangers and difficulties, and to suggest ways in which all who are concerned with science can help, as citizens, to make sure that its results, in fact, are beneficial.

Prof. Hill promptly disclaimed for scientists as such any title to superior wisdom or virtue, but proclaimed uncompromisingly that the fundamental principle of scientific work is unbending integrity of thought, following the evidence of fact wherever it may lead, within the limits of experimental error and honest mistake; and since science is a universal interest of mankind, recognizing no barriers of race, class, religion or honest opinion, a necessary condition of scientific advance is goodwill, friendliness and frankness. There is more to science than integrity and goodwill, but these are the qualities chiefly required to utilize the opportunities, and to resolve the problems and difficulties which science has provided for society to-day.

Prof. Hill's address amply illustrates the truth of his own words. Denunciation is unlikely to follow his exercise of the right he claims to discuss not only scientific facts themselves but also their consequences in human affairs; but his address may well provoke controversy, though scarcely comparable with that provoked by Tyndall's presidential address to the Association in Belfast seventy-eight years ago. When new knowledge and traditional beliefs are in conflict men are apt to forget Lord Kelvin's words: "Science is bound by the everlasting law of honour to face fearlessly every problem that can fairly be presented to it".

In reading Tyndall's address to-day, one is impressed, as Prof. Hill remarked, by its reasonableness as well as by its courage. Even when the Association next met in Belfast, in 1902, Tyndall's claim that science would wrest from theology the entire domain of cosmological theory had been practically conceded. Tyndall's words were then seen in their proper context and he was recognized, as Dewar pointed out in his presidential address that year, as no mere materialist, but one who recognized the immovable basis of the religious sentiment in human nature, bringing completeness and dignity to man. Tyndall had admitted that the whole process of evolution is the manifestation of a power absolutely inscrutable to the intellect of man, and acceptance of the necessary limits of scientific inquiry was then perhaps more common than it sometimes is to-day, while his dictum that "every system must be plastic to the extent that the growth of knowledge demands" might equally have formed the text for Prof. Hill's address.

In fact, where we encounter what Prof. Hill calls the ethical problems presented by the advance of science there has been little change in the degree of objectivity with which questions are discussed. It will be noted that, while Prof. Hill starts from the concluding words of the Duke of Edinburgh's address, he promptly applies a corrective to any careless thinking that the Duke's earlier words as to the dependence of progress in almost every form of human activity upon the continued efforts of scientists might engender. "The improvement of man's estate by the application of human knowledge," said Prof. Hill, "is one of the loftiest of adventures: but a belief that it can be achieved by scientific methods alone, without a moral basis to society, is a perilous illusion." Prof. Hill then pointed out, frankly and fearlessly, some of the implications and consequences of advances in public health and sanitation and the control of disease which are often ignored by those framing plans for the development of backward and other areas, such as the Colombo Plan.

Not only is the population increasing but in many places the rate of increase is still rising. In India, a Government Planning Commission in a report of July 1951, "The First Five-Year Plan", dared to point out that, with all the effort that this Plan represented, it would be barely possible to restore by 1955–56 the pre-war standards in regard to food and clothing. Increasing pressure of population on natural resources in retarding economic progress and limiting seriously the rate of extension of social services so essential to civilized existence. Meanwhile there is more than danger that the emergency will result in an over-use of natural resources, leading by land erosion, deforestation and other factors to permanent and irretrievable loss.

This has already happened and is visibly happening now in many parts of the world. With a frankness to which Prof. Hill paid tribute, the Indian Report suggests the education of public opinion on the need for limitation, but it recognizes also that an alteration in population trends takes at least a few generations to materialize. Meanwhile the combating of malaria with insecticides and anti-malarial drugs, of tuberculosis and cholera and other diseases, and the improvement of rural and industrial health, must be recognized as involving a further addition to the population of a million people per annum. Biological, medical, chemical and engineering science, applied for motives of humanity, with no objectionable secrecy, has thus led to a problem of the utmost gravity, demanding for its solution all the resources of science, humanity and statesmanship.

Prof. Hill's address should dispose of the comfortable illusion that it is merely a matter of food supply. The demands which a higher standard of living and an increasing population make on all natural resources are equally disturbing. Prof. Hill has the courage to face the unpleasant but inescapable questions of what reasonable limits are to be placed on human rights, and whether such rights extend to unlimited reproduction while those concerned are screened from its consequences by the discipline and care of others. Such questions have to be fac with courage and honesty and without prejudic They will not be solved by words or by tempo ization.

By taking as example one in which the motives those who made the original discoveries or t humanity of their applications can scarcely be call in question, Prof. Hill made clearer the ethic dilemma implied in such questions as the limits, any, which should be placed on scientific resear and the authority which should determine any su limits, and the wisdom of insisting that all scientif knowledge should be fully and openly disclos without secrecy or reservation of any kind, milita or industrial. The somewhat arid discussions regardin secrecy in nuclear physics are set by him in the wid context of the standards and principles without whic civilization would be permanently and indefinite poorer. If ethical principles deny our right to do ev in order that good may come, are we justified, h asks, in doing good when the foreseeable consequen is evil? Suppose it is certain now that the pressu of increasing population, uncontrolled by disease, w lead not only to widespread exhaustion of the s and of other capital resources, but also to continuin and increasing international tension and disorde making it hard for civilization itself to survive, wh then should be our policy?

Books like "Four Thousand Million Mouths", "Th Geography of Hunger" and "Soil and Civilization", well as some discussions on the development of bac ward areas, have made many in recent months awa of the danger. The ethical dilemma could scarcely b more frankly or better stated than in Prof. Hill address. Moreover, not the least of its merits is tha following the pattern of the Duke of Edinburgh address last year, it helps further to dispel th idea that science and technology are magical mysterious activities, apart from the ordinar occupations of men and women and beyond the comprehension.

That Prof. Hill's address thus contributes to clearer understanding by the ordinary citizen of th nature of scientific work, and especially of the exten and limits of the scientist's responsibility, is the mor important because the address is first and foremo a summons to frank and free discussion. Such di cussion should be the freer from prejudice on th account, and it is to be hoped that it will be marke by both the courage and the integrity for which Pro Hill appeals, to the layman no less than to th scientist. The dilemma is, as he shows, not on peculiar to the scientist: it is one which the scienti shares with his fellow citizens, and besides makin plain to the general public the position of the scientis Prof. Hill insists that to help to guide the use scientific discovery aright is the honourable an compelling duty of a good citizen, whether or not h be also a scientist.

The first need is full and free discussion; but ca should be taken to see that this is not provoked ways that hinder the co-operation between scienc and religion, between the scientist and his fello citizens upon which, like Tyndall, Prof. Hill insist ich co-operation is only possible on the basis of ourage and integrity, and his address is full of plications both for the conduct of political life as ell as for the scientist. Moreover, remarks that read lmost as asides to the scientist in the address are lated closely to this question of co-operation. The arning that the use of the general prestige of science s a bait to attract attention to pronouncements on ther topics is a disservice both to science and to the ublic has its implications for the layman as well as e scientist, but bears very closely on the question f mutual confidence on which co-operation largely epends.

From this point of view Prof. Hill's remarks on the roblem of secrecy in such matters as nuclear research [illegible] practical suggestions to scientists should be oted. They are entirely relevant to his main theme. y considering the ethical basis of their work and ankly discussing the moral considerations which nter in, scientists will go far to establish a confidence n their responsibility and integrity which some ecent episodes have shaken, but which is the nly possible basis for the co-operation and understanding which can reduce these grave problems to anageable dimensions.

Controversial though some of the issues this address aises may be, it is marked by the same reasonableness nd courage that characterized Tyndall's earlier ddress, and its humane outlook and keen sense of oral and ethical values, no less than the modesty nd integrity of its thought, should at least prevent ontroversy from being embittered. Prof. Hill has hown the right way to approach these acute and angerous problems of population and world order nd the utilization of world resources. He indicates learly the limits of the scientist's responsibility, as oo, he impresses on the scientist the need for clear hinking about the ethical basis of his work.

His appeal for responsible discussion is addressed o scientist and layman alike. How far the co-operation he urges will prove effective it is impossible o say. There are too many examples of the way in which religious or national prejudices can override the rational discussion of problems of welfare nd development, even to their own immediate material disadvantage, to be over-optimistic, even without regard to the immense cost and effort required for an education campaign which would quip the backward peoples of the world to meet some of the demands for self-discipline which the situation requires. Nor is education alone adequate o supply the moral qualities which such self-discipline mplies, as we can plainly see in our own and other Western nations.

But without such co-operation there can be no approach made to the solution to the grave problems Prof. Hill passed in review. Co-operation between layman and scientist, as good citizens in the discharge of a common responsibility and in the formation of those judgments of value which in the end determine the use we make of science, is the first step. Ultimately the problem we have to solve, whether as scientist or as layman, is one in the responsible exercise of power, and its solution depends on whether man, having learned to command Nature, can now learn to command himself before he destroys civilization.

To do this is, in Tyndall's phrase, to gain "completeness and dignity", and success depends, as Prof. Hill clearly indicates, not on our resolution of some special ethical dilemma, peculiar to scientific men, but rather on the resolution of the so-called conflict between religion and science. It calls for the use of science to express and apply the principles of ethics, and the use of those principles to guide the conduct of scientific men. In the appreciation of what is good and beautiful, Prof. Hill finds for layman and scientist the vision that can encourage both in the task to which his address summons them.

REPORTING SCIENCE

THE scientific thought of the Western civilization is as much a part of our culture as the developments in the humanities which originated in the Greek and Jewish writings and were nurtured and grew in the centuries of the Christian era. But science, if only in some of its technological manifestations, touches and even moulds the lives and destinies of those who are not interested in culture in its narrow sense. Each year the problem of reporting the results and implications of scientific discovery becomes at once more important and more difficult, but only by communication can we have a true community. It is more important because more of our fabric of living, individually and socially, is dependent on the application of science, and more difficult because, with the increase in the techniques employed by men of science, there has been an increase in the number and complexities of scientific modes of expression. Not only new words and phrases, but also new symbolisms and mathematical calculi are part of the current linguistics of science. Even some of the simplest of processes and expressions used in the calculus of statistics, so valuable in the biological sciences with their applications to human needs, involve great logical difficulties, both mathematical and verbal, for all but comparatively few people.

Because of the present shortage of well-qualified science teachers, even many children who are prepared to take science for the General Certificate of Education (and this is not a large proportion in view of the needs) are not in their adolescent and adult life prepared to understand the significance of the new discoveries of science. In the whole field of adult education in Britain, classes in the sciences account for only 7 per cent of the whole number. Although it is difficult to find suitable tutors, sufficiently well-read in the sciences, and skilful enough as teachers and leaders in adult classes, there still remains the fact that science is not popular, in the true sense of the word, with adults.

The task of explaining science to those whose work lies in some other field is not a new one. In 1633, Phineas Fletcher wrote "The Purple Island" in which he versified physiology. Erasmus Darwin, always optimistic concerning the scientific education of the "ordinary" man, produced "The Botanic Garden" (1789) in rhyme. Fortunately such poetical attempts have not often been followed up, though writers such as Auden have attempted to illuminate the picture of the scientific environment with poetic insight. More than in any other country, British men of science have been able to write clearly and elegantly in their mother tongue. Many have produced work which, quite apart from any scientific significance, has also literary merit. The nineteenth-century writings of Tyndall, Lyell and Charles Darwin still stand as literature. Those of Francis Bacon, Robert Boyle, T. H. Huxley and Gilbert White, to mention a few at random, can be read with pleasure and sometimes with ease. Coming nearer to our times the books in Britain of James Jeans, A. N. Whitehead and J. W. N. Sullivan, whose early death was a great loss to scientific literature, and in the United States the works of Beebe, Sears and, very recently, Rachel Carson, are examples of a good type of vulgarization of science. Nearly all of these writers were men of science.

But what of the reporter who is not a scientific worker, but whose task it is to present news which has to compete in popularity with other forms of news designed to attract public interest and to hold it at any rate until something at least as interesting appears? It would be trite to say that his contribution both in content and emphasis must vary with the type of reader for which his paper caters. It is significant that the only reference in several of our national papers to some dozens of important discourses given during one of the days of the meeting of the British Association for the Advancement of Science in Edinburgh last year was the fact that an important paper on coal supplies had been interrupted with asperity by a "local resident". No doubt this unseemly incident was much better news to those who love sensationalism than a carefully conceived account of the tremendously important fuel and power problem as it will confront our children. It is impossible to blame the reporter or his paper. The matter always returns to the fundamentals of popular education, its contents and its aims.

In the United States, where there is a much greater demand for books and articles on science, and probably also a larger percentage of people who are interested in science, or at least in technology, the reporting of science has had more consideration as to its aims and nature and more organization than it has in Britain. Most of the American writers who report science for newspapers and magazines belong to the National Association of Science Writers which was founded in 1934 for the express purpose of promoting accurate and responsible science reporting. The membership at the present time is upwards of 150. The National Association of Science Writers is affiliated with the American Association for the Advancement of Science.

American publishers and editors say that they have found that it is better to train experienced reporters in science rather than to hope to find sufficient men of science who are able or free to undertake tl type of work. Incidentally, the proper reporting such incidents as a fire, where there is a sequen of observable events, is said to be part of a suitab training of such a reporter; for not only is it necessa to take cognizance of a developing phenomenon, observe true chronology in a chain of events, bu the reporter must also bring to his work an arresti and lively style of writing which will make b 'contribution' compete with that of other news.

Whether he likes it or not, the man of science making history and his work should be explained such.

A number of our American contemporary *Scien* (April 18, 1952) says "good science reporting cou help science itself by explaining research proj[illegible] a public that ultimately pays many of the bi Thanks to accurate reporting of medical and publ health news in newspapers and magazines during tl past few decades, the general public should be fairl well informed on such matters. . .".

Yet with less organization and less advertisemen the quality of writing on science is probably bett in Britain than in any other country. There ca be no doubt that the American Rachel Carson's "Th Sea Around Us" is a good work; but it is, to say th least, no better than the excellent British work "The Ocean", by F. D. Ommaney, and "The Seas' by F. S. Russell and C. M. Yonge, which i splendidly illustrated in colour. Why is the first best-seller, and why did the last have to wait eigh years before a second edition appeared? The answe is probably to be found in advertisement, a matte which is anathema to most men of science.

In the end, charm they never so wisely, the wor of the best science writers will be ineffective unle it is prepared for by a more general and lively teacl ing of science in all types of secondary school, and i this connexion here is No. 1 priority.

BIRD PARASITES

Fleas, Flukes and Cuckoos

A Study of Bird Parasites. By Miriam Rothschil and Theresa Clay. (New Naturalist Series.) Pp xiv+304+40 plates. (London and Glasgow: Wm Collins, Sons and Co., Ltd., 1952.) 21*s*. net.

THE avowed aim of the New Naturalist Series i to interest the general reader in the wild-life o Britain, and the present volume is an outstandin example of the way in which a somewhat specialize branch of natural history—often regarded as 'no quite nice'—can be made of absorbing interest no only to the professional zoologist and amateu naturalist but also to the general reader. Th authors, both distinguished for their work in differen fields of parasitology, have selected the most intensively studied animals of the world—birds—as th starting point for the development of a picture of th vast network of organisms which they harbour bot inside and outside their bodies. This community o parasites comprises animals, plants, bacteria an filterable viruses, whose relationships, life-historie and general biology are very little known.

It is rather surprising that parasitology, a subject resenting so many fields for investigation, should ot have received more attention—at least in Great ritain—for parasites comprise a far greater number f both species and individuals than their hosts. The axonomist will find in them a very wide range of nterest, for to take only one example, the 500-odd ritish birds support very many thousand different arasites, including at least 1,500 species of Mallohaga, few of which have valid scientific names. ertain groups of parasites have been used for trying o demonstrate the true systematic relationships of heir hosts. The Mallophaga, for example, are ighly host-specific, each species being confined to ome particular host, and their evolution has resulted n related birds for the most part harbouring related allophaga. Similarly each order of birds has its wn particular cestode fauna, and the fact that rebes and divers harbour quite distinct tapeworms uggests that these two groups of birds should ot be placed together in any natural scheme of lassification.

The life-cycles of such parasites as trematodes, estodes and nematodes are strange and wonderful, enerally involving perilous journeys through different osts, with a survival-rate from egg to adult of much ss than one in a million. Yet, as pointed out by the ditors of this series, there is not even one worker in ritain wholly occupied with the trematodes or flukes.

The physiology of most parasites is completely nknown; but the little information which is available suggests the existence of highly specialized etabolisms well worth the study of biochemists.

The authors include a general introduction in which arasitism, commensalism, symbiosis, the effect of arasites on their hosts and parasitism on parasites, nd related problems are discussed. After dealing ith the various groups of parasites, ranging from icro-organisms to the arthropods, including a hapter on the fauna of birds' nests, there is an ccount of the brood parasitism in the European uckoo.

The authors are to be congratulated on the production of a book combining so pleasingly both wit nd erudition; it should certainly find a place in very naturalist's library.

E. HINDLE

GENETICAL STUDY OF EVOLUTIONARY PROCESSES

enetics and the Origin of Species

y Prof. Theodosius Dobzhansky. (Columbia Biogical Series, No. 11.) Third edition, revised. Pp. +364. (New York: Columbia University Press; ondon: Oxford University Press, 1951.) 32*s*. 6*d*. et.

T is good to see a new edition of Prof. Dobzhansky's "Genetics and the Origin of Species". The revious edition appeared in 1941, and in ten years great deal can occur in so active a science as the enetical study of evolutionary processes. The many ho valued Dobzhansky's earlier editions will look the new one for an equally informative account of e position as we see it to-day.

The basic principles of the genetical theory of olution are, of course, unchanged. This theory sts on the postulates that heritable variation occurs populations of living things and that, as a consequence, the populations may undergo permanent changes. So in seeking to understand how adaptation and evolution come about, we must inquire into the nature, occurrence and origin of variation in natural populations; into the ways in which heritable variants bring about changes in the structures and properties of these populations; and into the means by which they come to be fixed, both uniformly within populations and differentially between them. In that it is explicitly built round these principles, Dobzhansky's third edition is like its predecessors; but in seeking to take into account the developments of the past decade it has had to be almost completely rewritten.

Ten years ago the discussion of variation centred on mutation and especially on the occurrence of changes which were either visible in the chromosomes themselves or, if genic in nature, produced drastic effects on the phenotype. The growing realization of the importance of continuous variation has moved the emphasis towards the storage of variability, the properties of balance, and the relations they bear to recombination. Dobzhansky's own experimental work has made a major contribution to this development and indeed his studies of variation and balance in wild *Drosophila*, summarized in the new edition, have an elegance and finality which few can fail to admire. All this is reflected in the book, the old being condensed and the new brought out, with perhaps that trace of conservatism understandable in a work which is likely to be so widely quoted.

In discussing selection, Dobzhansky is now able to draw on a much greater wealth of experimental evidence, including, as in the case of mutation, information from micro-organisms. As a consequence, drift, though by no means forgotten, looms less heavily in the consideration of agencies affecting the fate of variants in wild populations. Indeed the part played by drift is necessarily seen in a different perspective when considering the properties of systems of genes than when discussing the fate of single major variants.

Isolating mechanisms, by which genetical diversity is preserved, are again given just prominence. The distinction is drawn between bars to crossing, which can arise by selective action, and hybrid incapacity, which cannot be ascribed to direct selection, and their inter-relations discussed. Hybrid breakdown receives, however, a fuller treatment than do bars to crossing, doubtless because of the greater wealth of experimental evidence about it, especially in animals. This is a matter of emphasis which time can be expected to change. The study of plants has much to offer here, as it has had in laying before us the variety of ways in which a species governs its own breeding structure and genetical composition—a matter on which a geneticist more directly concerned with plants would perhaps have laid rather greater stress.

Argument about emphasis must not, however, be allowed to obscure the value of Dobzhansky's book. The new edition will be as widely appreciated for the picture it sets before us of things as they are to be seen now, as its predecessor was for giving us the picture of 1941. "Genetics and the Origin of Species" has the rare merit of moving with the times—times which Prof. Dobzhansky has himself done so much to move; and it has the even rarer merit of changing not merely by accretion of the new but also by judicious shedding and condensation of the old; for, most remarkable of all, the third edition is in fact shorter than the second.

K. MATHER

HETEROCYCLIC COMPOUNDS

Six-Membered Heterocyclic Nitrogen Compounds with Four Condensed Rings

By C. F. H. Allen, in collaboration with D. M. Burness, Jean V. Crawford, F. W. Spangler, Eleanor R. Webster and C. V. Wilson. (The Chemistry of Heterocyclic Compounds, Vol. 2.) Pp. xiii+345. (New York and London: Interscience Publishers, Inc., 1951.) 10 dollars.

Thiophene and its Derivatives

By Howard D. Hartough; with Special Chapters by F. P. Hochgesang and F. F. Blicke. (The Chemistry of Heterocyclic Compounds, Vol. 3.) Pp. xvii+533. (New York and London: Interscience Publishers, Inc., 1952.) 16.50 dollars.

THESE two volumes are the second and third, respectively, of a series of monographs which are designed ultimately to cover the entire field of heterocyclic chemistry.

The contents of the second monograph of this series, "Six-Membered Heterocyclic Nitrogen Compounds with Four Condensed Rings", call for rather careful description. Regarding pyridine as aza-benzene, it will be appreciated that several poly-aza-benzenes are conceivable and, since the fusion of four benzene rings gives rise to seven distinct aromatic structures, the possible aza-analogues of these and of their hydroaromatic derivatives must be very numerous indeed. Relatively few are known, however, and in the present volume the number is further reduced by exclusion of benzacridine and benzophenazine types and of all compounds in which nitrogen as hetero-atom is shared between rings. Subject to these restrictions the compounds are classified and treated in the following order: aza- and poly-aza- derivatives of naphthacene, benz[*a*]-anthracene, benzo[*c*]phenanthrene, chrysene, triphenylene, benzanthrene and pyrene. Further subdivision is based on the number and position of the nitrogen atoms in the molecule, and sectional discussions are followed by descriptive lists of individual compounds, complete with references to the end of 1950. Nomenclature is treated in a rational manner, and, as is explained in the preface, an attempt is made through a comprehensive index to anticipate and cope with the difficulties of those who consult the volume on a particular quest.

The method of presentation is open to the criticism that it uses a canvas which is too large for the present-day picture. Apart from certain groups of dyestuffs and alkaloids of the chelidonine and aporphine types, there has been little systematic investigation and still less correlation among the known compounds of the class. None the less, it is the authors' achievement to have rescued this family of heterocycles from its interment in the journals or from, at best, the seclusion of dispersed and neglected paragraphs in major text-books. The volume is not only a record of existing knowledge but also, both explicitly and by implication, it points the need and marks a field for future research.

The monograph on "Thiophene and its Derivatives" presents, in fifteen chapters, a comprehensive account of these compounds, covering published work almost to the end of 1949. An additional chapter deals with selenophene and tellurophene analogues, but compounds containing condensed ring systems are reserved for a later volume. The earlier chapters contain such general topics as the history, occurrence and synthesis, together with the general physical an chemical properties, of thiophene and its homologue A special chapter (contributed by F. F. Blicke describes the toxicology and pharmacology of th compounds. Another special chapter (by F. F Hochgesang) presents an informed discussion of th molecular structure and spectroscopy: it contain diagrams and tables relating to ultra-violet an infra-red absorption spectra, together with mas spectral data, as obtained in the author's industri laboratory. A helpful survey of factors affectin substitution in the thiophene nucleus precedes th systematic treatment of the various classes of thiophene derivatives, which occupies the major portio of the book. The treatment here is both authoritativ and critical: it is kept within reasonable limits b the judicious use of tabulated information, all o which is fully documented. Each chapter is provide with an appropriate set of footnote references, and in an appendix, laboratory preparations are given fo some thirty representative thiophene derivatives. A efficient index completes the volume, which wil undoubtedly become a standard work of referenc for thiophene chemistry and, in its early chapters a least, will amply repay the attention of the genera reader of chemistry.

QUANTUM MECHANICS OF VALENCE

Valence

By Prof. C. A. Coulson. Pp. x+338. (Oxford Clarendon Press; London: Oxford Universit Press, 1952.) 25*s*. net.

DURING the past twenty-five years the application of quantum mechanics to the problem o the structure of molecules has led to great clarificatio of the chemical concept of valence. Prof. C. A Coulson, who has made important contributions t the subject, has pointed out that every chemis should have an understanding of the quantu mechanical theory of valence, and he has written book, as a supplement to the text-books of chemistry to provide a basis for this understanding.

Chemistry is a large subject; and quantu mechanics, even the parts of quantum mechanic that relate to chemistry, is also a large subject, an quite different in general character. The problem o presenting quantum mechanics in relation to chemistr in a short book in such a way as to be helpful rathe than confusing to the student is a difficult one Coulson has attempted to solve it by giving sketch accounts both of the mathematical methods of quantum mechanics and of the facts of structura chemistry. In his book the empirical system (th chemical system) of valence and molecular structur is discussed only briefly. The quantum mechanica system, however, is also presented rather briefly an superficially. It is my opinion that a student (th author says in the preface that the book is intende for chemical students) needs to build up a solid an complete framework of one sort or another, withou gaps. Although the author states that practically n mathematics is needed for his purpose, the boo contains many quantum mechanical equations, som of which are obtained from earlier equations in th book by methods that are not presented to th reader. This treatment—which might be calle escriptive quantum mechanics, as opposed to heoretical quantum mechanics—may be suited to some readers, but I fear that many would be confused y it.

Both the valence-bond method and the molecular rbital method are used in the discussion of the structure of covalent compounds. The author has llowed his enthusiasm for the molecular orbital method to lead him to make some statements that robably cannot be supported. Thus, after presenting molecular orbital treatment of the carbon monoxide molecule, he says that the description of this molecule s resonating among three valence-bond structures is ar less satisfactory. However, the molecular orbital treatment that he presents involves a serious error; the assumption is made that the oxygen atom uses $2s$ orbital for an unshared pair, and a $2p_x$ orbital or the σ bond, but that the carbon atom uses hybrid ond orbitals $\frac{1}{\sqrt{2}}(s + p_x)$ and $\frac{1}{\sqrt{2}}(s - p_x)$ for its unshared pair and σ bond, respectively. The consideration of the energy of promotion of an electron from the $2s$ orbital to the $2p$ orbital shows that, in act, the unshared pair for each atom occupies a ybrid orbital that is predominantly $2s$ in character, with a small contribution of $2p_z$, whereas the σ bond rbital is largely $2p_x$ in character, with a small contribution of $2s$. The same error, resulting from eglect of the $s-p$ promotion energy, occurs in the discussion of hydrogen chloride: the author describes the orbital for the σ bond and the orbital for the unshared pair of the chlorine atom as involving qual amounts of $3s$ and $3p_z$ character, whereas, in fact, minimizing the energy with consideration of the $-p$ separation shows that the σ bond orbital is predominantly $3p_x$, with only about 2 per cent of $3s$ haracter, and that the unshared-pair orbital is predominantly $3s$, with only about 2 per cent of $3p_x$ haracter.

In twenty-five years the quantum mechanical heory of valence has become an important part of hemistry. It is still undergoing change, as a result of the efforts of Prof. Coulson and other workers in he field; and we may hope that in another decade or two a satisfactory solution can be found of the problem of presenting the subject to the chemical tudent, a problem which Prof. Coulson has tackled in his book on valence.

LINUS PAULING

MODERN PLANT TAXONOMY

Stages in the Evolution of Plant Species

By Jens Clausen. Pp. ix+206. (Ithaca, N.Y.: Cornell University Press; London: Oxford University Press, 1951.) 22*s*. 6*d*. net.

TAXONOMISTS are, on the whole, conservative, in the sense that they are cautious in introducing what may be far-reaching changes in their methods. There are two valid reasons for such caution. First, hanges in classification affect not only taxonomists hemselves, but also, since taxonomy is basic to all other branches of biology, changes in taxonomic concept or even nomenclature have repercussions over a wide field. Secondly, the taxonomist knows rom experience that data as supplied by geneticists, ytologists, ecologists and other progressive modernists are sometimes inaccurate, and he may prefer to wait until they have been several times checked before incorporating them in his schemes as characters of taxonomic value. Nevertheless, most taxonomists acknowledge that much improvement in classification can result from a consideration and incorporation of evidence derived from experimental studies, cytological investigations, the analyses of large wild populations, and detailed researches into ranges and distributions. Doubts, however, are at times expressed whether such data from new lines of investigation can be satisfactorily combined with the morphological characters on which orthodox taxonomy is largely based. In other words, it is questioned whether a general classification utilizing all ascertainable characters can be prepared, or whether the theoretically possible limit is a number of special classifications. This most interesting book now under review strongly favours the view that a synthetic classification can be prepared, at least for taxa up to the size of genera.

Dr. Jens Clausen, in co-operation with Dr. D. D. Keck and Dr. W. H. Hiesey, has carried out a large series of comparative researches, involving field studies, transplant experiments, crossings and selfings, cytology, and taxonomy on a number of genera of the Californian flora. The results are summarized in a very attractive form in what are called eight essays that were given as lectures under the Messenger Foundation at Cornell University during November 1950. After an outline of the history of our concepts of speciation, Clausen logically deals in turn with local populations as the basic evolutionary unit, ecological races and morphological subspecies, interspecific barriers, the evolution of groups of species, and the physiologic–genetic species concept and the dynamics of the evolution of species and genera.

Clausen and his colleagues are fortunate in having almost ideal conditions for the kind of researches they have carried out and are continuing: the natural environments in California are varied; the native flora is a large one; the Carnegie Institution of Washington has wisely provided funds for the long-range researches; and three experimental stations at different altitudes have been established. That these and other advantages have been so fully used is to the credit of Dr. Clausen and those who have worked with him.

The half a dozen or so groups of species dealt with in some detail give a very varied picture of speciation. It is proved that this occurs in many ways, by steps of different sizes, over longer or shorter periods of time, and often irregularly. "We find species in all stages of differentiation. The most distinct ones, those that are the end products of the processes of speciation, differ in morphological characters, in ecological fitness to the environment, in the genetic systems by which they control this fitness, and in the homology of the chromosomes. The differentiating processes, however, do not always proceed simultaneously at the same rate along all the fronts mentioned. In ecological races of one species, physiological differentiation precedes the morphological and the genetic. In other cases morphological differentiation will be far ahead, and in still others, genetic separation begins even before physiological differences have enabled the forms to occupy different environments, or before morphological differences have provided satisfactory taxonomic labels for distinguishing the species. The most normal pattern of speciation, however, is a more or less simultaneous and gradual separation in morphologic, ecologic, genetic and cytologic characteristics." Again, "The species exist in all stages of ecologic, genetic, cytologic, or morphologic distinctness, some preponderantly morphological, others preponderantly genetical, and still others preponderantly ecological".

The importance of genetical barriers between taxa is rightly emphasized, but it is explicitly stated (p. 158) that hybrid sterility or genetic incompatibility is not believed to be the sole criterion of specific distinctness. Examples quoted in several places in the body of the book show that it is not invariably an essential criterion. Isolating mechanisms are of many kinds, and every one has numerous variants.

One criticism may be made. I doubt if the statements regarding clines (p. 28) are valid. It is there said, "The term cline can be used only for individual characters, and not for an assemblage of characters of groups of individuals such as a series of populations, for a single individual may with respect to one character belong to one cline and with respect to another character to a different cline. Clines are therefore not commensurable with natural entities, and are oversimplified abstractions dealing with the variation of individual characters". There is, however, sometimes found to be a high correlation of character variations as the individuals of a cline are scored in a given direction.

Every taxonomist and every botanist, whether a taxonomist or not, is urged to read and consider this book. Very many portions could be quoted from it as proof of the truth of the final paragraph: "Even though we may think we dimly see some of the organization in the intricate network that connects the life of today with that of the past, we still do not know what enables living things to develop as they do, or how they first came into being. The research of the present century has merely opened our eyes to see a remarkable and still quite incomprehensible organization of living things. Faced with such a situation, the scientist becomes humble, for at this point he meets the Great Unknown".

W. B. TURRILL

THE STONE AGE IN EASTERN PALESTINE

Le paléolithique et le mésolithique du Désert de Judée

Par René Neuville. (Archives de l'Institut de Paléontologie humaine, Mémoire 24.) Pp. 270+20 plates. (Paris: Masson et Cie., 1951.) n.p.

THIS is an important work which gives new information on the prehistory of a hitherto little-known region. The area of exploration lies to the south-east of Jerusalem in semi-desert calcareous country stretching eastwards to the Dead Sea. A number of cave and rock-shelter sites have been excavated and rich flint material unearthed. Culturally speaking, the industries found range from Tayacian and late Acheulean through Mousterian (in one instance, of the Kurdistan variety) to a late Palæolithic and Mesolithic (Natufian). In at least one site this last-named passes upwards into a Tahunian, which recalls the industry of the lower levels at Jericho. The Stone Age folk must have occupied many of the sites for long periods of time. Their industries show steady evolution; for example, there are no less than three Natufian levels with development from the early level to the latest Important is the proof that the Tayacian cultur must have existed side by side with the late Acheulean. These two cultures belong to two distinc culture groups, and their co-existence at the same time in this part of Palestine is interesting.

But the author and his collaborators have no been satisfied merely to dig the sites and then to publish accounts of the industries and fauna recovered. Their main interest has been to place the cultures in their geological and climatic settings. A succession of pluvial and interpluvial period can be demonstrated, roughly coincident with the glacial and interglacial ones of more northern latitudes. There must obviously have been much wetter periods in this region in the past than nowadays, as to-day the country is only able to carry a very small population. Into the framework thus arrived at it has been possible to fit the successive cultures and to compare the results with what is known in other parts of the world.

The volume opens with a general description of the area, and this is followed by an account of the various sites excavated and a description of the finds unearthed. There are plenty of line drawings, both of the implements and of the fauna, and also twenty plates which supply further illustrations. No works of art were encountered except in two cases in Natufian levels where sculptures were discovered This accords with Prof. Garrod's work at Mount Carmel, where, too, sculpture was encountered in Natufian levels. There is no doubt of the importance of this work to all students of the Stone Age in this part of the world.

M. C. BURKITT

CHEMISTRY IN THE INDUSTRIAL REVOLUTION

The Chemical Revolution

A Contribution to Social Technology. By Dr Archibald Clow and Nan L. Clow. Pp. xvi+680+110 plates. (London: Batchworth Press, Ltd., 1952.) 50s. net.

WHEN a reviewer sees what by present-day standards is a large and well-produced volume entitled "The Chemical Revolution", he has visions of a historical account of the way in which chemical discoveries and their technological and commercial applications have revolutionized man's way of life how they have brought him new sources of wealth of health, richness of life, new possibilities of professional employment and new techniques of construction.

In the present volume the authors have limited themselves both in time and space in their treatment of the enormous field suggested by their title. Even so, it is quite impossible to deal adequately in this short notice with so important a work. The book treats of the chemical industry as an important concomitant of the Industrial Revolution until about the middle of the nineteenth century.

It was said of the study of acoustics, by Clerk Maxwell, that whole armies of musical scientists and of scientific musicians had fallen into that Serbonian bog without in any way filling it up. In a similar way, the scientific historians, economists and 'historical' scientists who will be required to deal with the subject under review will be legion.

The authors modestly say that they have said the rst word on the subject and not the last. In the mitations which they have set themselves they have chieved a remarkable synthesis from the almost nexplored ground common to economic history and hemical technology. In manuscript the work was warded the Senior Hume-Brown Prize by the niversity of Edinburgh; and, if the book is mainly evoted to the work of industrial scientists of North ritain, we can concede with the authors that "a alaxy of Scotsmen gave scientific direction to the ndustrial Revolution, particularly in its hitherto eglected non-mechanical aspects". The writers have ound inspiration in Lewis Mumford's "Technics and ivilisation" and have adopted his terminology, xtended from that of Patrick Geddes—"one can ivide the development of the machine and the achine civilization into three successive but overapping and interpenetrating phases: eotechnic, alæotechnic and neotechnic. Speaking in terms of ower and characteristic materials, the eotechnic hase is a water and wood complex, the palæotechnic hase is a coal and iron complex and the neotechnic hase is an electricity and alloy complex". The uthors do not go beyond the first two phases.

The chief subjects in the book are minerals and anufacturing processes, the economy of common alt, ashes and kelp, the palæotechnic transition and itriol in the Industrial Revolution. The chemical ndustry is the most polygamous of all industries, nd Justus Liebig's famous *bon mot* of 1843, "We ay fairly judge of the commercial prosperity of a ountry from the amount of sulphuric acid which it onsumes", comes with even more point to-day. here are sections on balloons, bleaching and dyeing before the days of Perkin), calico printing, mordants nd mackintoshes. The considerable quantity of mmonia which was required for some of these rocesses was obtained from urine (a common ractice being the dilution of this personally produced roduct by the canny Scots, until the use of a specially esigned hydrometer put a stop to this 'minor acket'). The glass, iron, gas and tar, agricultural rmentation, the sugar and food industries are all ealt with by the historical–economic–sociological ethod. There is a useful chemical chronology from 610 until 1856, and a glossary of dead chemical anguage, though some of the terms are still very uch alive.

The book is a model of scholarly presentation, and is fully documented and indexed. It is a handsome olume with 110 plates, including a reproduction of coloured print of the old iron-works at Coalbrook ale and a number of diagrams; and it is a pity hat present-day costs necessitate a price of fifty illings for the work.

W. L. Sumner

THE FILM IN EDUCATION

he Film in Education

y Dr. Andrew Buchanan. Pp. 256+25 plates. London: Phoenix House, Ltd., 1951.) 25s. net.

EVERYONE agrees that films can and should play an important part in education. Yet practice nd realization fall far below theory and ideal: rogress has been slow. The reasons for this sorry tate of affairs form a complex network. For example, here is a lack of the research which would guide both roducers and users: we do not fully know how people look at pictures or diagrams, how they gather information from them, what features are truly significant. There are economic obstacles: visual material is expensive to produce, the market is small, the risks of failure great. Perhaps more important than such difficulties is the persisting traditionalism of teachers accustomed to rely on the written or spoken word, desensitized by their training to the appeal and meaning of visual presentations, uncertain of the best ways of using films in teaching, uninformed regarding sources of visual material, timid in their use of projection apparatus.

Dr. Andrew Buchanan has long been known as a producer of outstanding educational films, and he has done much to popularize their use in schools and universities. He has drawn on his experience to produce a book which will certainly become a standard work of reference. It should be noted, however, that he has imposed restrictions upon himself and that his book is far from being a comprehensive treatise on visual education. He makes little mention of film-strip, wall-chart, printed pictures, etc., nor does he deal with methods of displaying visualizations other than optical projection. There is very little fundamental discussion and few references to psychological or research data. In a word, the title well describes the book—but this particular restriction of necessity impoverishes the treatment.

Dr. Buchanan begins by speaking of the purposes, advantages and limitations of educational films, and goes on to the use of films for specialized purposes in medicine, science and art. He describes the development of such films in many countries and considers the contribution of Unesco. He devotes chapters to a detailed description of the planning, production and distribution of visual aids, taking account of the increasing part taken by the National Committee for Visual Aids. These chapters are of real value since this kind of information is essential to teachers who desire to collaborate fruitfully with professional producers. The author goes on to give advice on the method of handling projectors and suggests ways of conducting discussions with classes who have watched films, so that they may really learn from them. In addition to all this, he has gathered valuable material regarding the effects on children of watching entertainment films, and regarding the views currently held by teachers on the films they would like to have.

One of the most interesting sections of the book is that in which Dr. Buchanan shows with figures that it is almost impossible to produce films for the small British market without incurring a loss, and that the British tradition of parsimony in educational administration militates against success. It appears that the establishment of the semi-official Foundation for Visual Aids has made the situation still worse by loading the scales still more against the producers.

Schools are by nature slow to change their ways or to adapt their practices to new conditions. Teachers are far less willing to adopt and employ new equipment or instruments than are workers in factories or offices; and, as was said earlier, our administrators have never learnt the lesson that education can be cheap or efficient but not both. In spite of all this, visual education has come to stay, and it will gradually affect practice and transform the process of instruction. Dr. Buchanan's book is a genuine contribution to the enlightenment of educators, and it may be warmly recommended to the attention of all who intend either to make or to use film.

THE ETHICAL DILEMMA OF SCIENCE

By Prof. A. V. HILL, C.H., O.B.E., F.R.S.
President of the British Association

EXACTLY a hundred years ago the British Association met for the first time in Belfast; and this year the Association is indeed happy to gather together in this city, to test its hospitality again and celebrate, with it a century of progress of British science. In 1660 the little town of Killyleagh, some twenty miles from Belfast, was the birthplace of Hans Sloane, botanist, collector, physician, and president of the Royal Society, on whose bequest to the nation the British Museum in London was founded: its two-hundredth anniversary will be celebrated next year. The following century produced Joseph Black, a pioneer in chemistry and the theory of heat, who was the son of a native of Belfast and educated there. In 1824, in this city was born William Thomson, Lord Kelvin, the famous physicist and inventor, his father, a native of Co. Down, being then a teacher of mathematics in the Royal Academical Institution, Belfast. Joseph Larmor, born in Co. Antrim in 1857, was taught at that school, and when he became Senior Wrangler at Cambridge in 1880, repeating the success of a schoolmate the year before, a torchlight procession was held in Belfast—to the bewilderment (as Eddington records) of the shy young mathematician. This city was the birthplace in 1866 of E. W. MacBride, the zoologist, also at the same school: those of us who remember him affectionately could never have imagined him coming from anywhere else. A dear friend of many of us, Joseph Barcroft, the physiologist, was born at Newry in 1872, and learnt what he knew of the things that really matter (as he truly said) sailing in Carlingford Lough. And among the living, Frederick Donnan, a native of Holywood, Co. Down, and a graduate of Queen's University, Belfast, whose imagination has fertilized both chemistry and biology, tells me that he took part in the British Association meeting in Belfast in 1902. Thus it goes on. British science owes much to the fertile and imaginative minds, the vigorous temperaments and the warm hearts of our kinsmen in Northern Ireland.

We can recall, too, that applied science is a partner in the great industries for which Belfast and Northern Ireland are famous: the city for shipbuilding, engineering and textiles; and the surrounding country for agriculture. In the report of the British Association for 1852 there is a description of the vortex water-wheel, an early form of turbine, in working use at a nearby mill: James Thomson, elder brother of Lord Kelvin and for many years professor of civil engineering at the then Queen's College, had patented a vortex water-wheel in 1850. In the same report is a long account, by the professor of agriculture at Queen's College, of the composition and economy of the flax plant; and thirty pages were devoted to the fattening of animals—English animals, it is true, but their cousins in Ireland have been apt pupils. In such practical arts, based alike on scientific knowledge and traditional skill, the contribution of Northern Ireland has been as distinguished as in the advancement of science itself; and it may confidently be expected that the present meeting of the British Association will serve not only to celebrate the achievements of the past century but also to foster the endeavours of the next.

The President for 1852 was Edward Sabin
astronomer, explorer and geodesist, a colonel then i
the Royal Artillery. Sabine at that time w
treasurer of the Royal Society, and at various othe
he was physical secretary, foreign secretary an
president: indeed, for completeness, he should hav
been biological secretary too, for his name occurs i
an index of British and Irish botanists, and in th
British Museum are plants collected by him o
Arctic expeditions. Sabine was an Irishman, and
the president this year is English, with an ancest
from Northern Ireland two hundred years ago, th
only emphasizes, after a century, the unity of scienc
Indeed, there are many Irishmen at this year
meeting from the other side of the border: they a
doubly welcome, for science admits no frontiers, an
customs duty is not levied on ideas or friendshi
Sabine's address referred particularly to the subje
of his own chief interest for many years, the periodi
variations of terrestrial magnetism: indeed, h
announced in his address the discovery of the con
nexion between sunspots and magnetic disturbanc
in the earth. He finished his address by referring t
"allusions . . . made by influential men . . . to
direct representation of Science in Parliament". Th
benefit, he said, which the legislature might deriv
from such a change was a question rather for state
men than for scientists; but as regards science itsel
he expressed his strong conviction that the possibl
gain would be far outweighed by inevitable loss, an
that scientific men could not too highly value th
advantage they possessed in the undisturbed enjoy
ment of their own pursuits untroubled by th
excitements and distractions of political life. Th
practical importance of science to-day, and its impac
on public affairs, have greatly reduced that undi
turbed enjoyment; and though all would agree tha
the direct representation of science as such in th
House of Commons is impracticable, none woul
doubt the advantage to Parliament and the nation
more of its members had some personal acquaintanc
with science. It might indeed be well, in a reforme
Second Chamber, to provide the same representatio
to science as at present is afforded to the Church an
the Law.

Two famous young Irishmen were present at th
Belfast meeting of 1852. William Thomson, Lor
Kelvin, elected to the chair of natural philosophy a
Glasgow six years earlier at the unusual age o
twenty-two, was president of the Section of Physics
the other, George Gabriel Stokes, then thirty-thre
delivered a public lecture on fluorescence due t
ultra-violet light passing through a solution of quinin
Both were among the foremost physicists of th
following half-century, and Kelvin succeeded Stok
as president of the Royal Society.

The next meeting in Belfast was in 1874, whe
another Irishman, John Tyndall, presided. H
notable address will be referred to later. Huxle
delivered an evening discourse with the provocati
title, "The Hypothesis that Animals are Automata"
whether for that or for some other cause, it is recorde
that he was threatened with assault by a no
conformist minister. On the lighter side, a descripti
was given of an old lady of 111 who chatted aw

continually in a clear voice, was in possession of all her faculties, took snuff, and had white hair and a skin as soft as velvet—which is encouraging to those who take snuff and have white hair.

The last meeting at Belfast was fifty years ago, in 1902, under the presidency of James Dewar, a Scotsman, famous for his work on the liquefaction of gases. Lord Kelvin, loyal to Belfast, read a curious paper n the Physics Section entitled "Animal Thermostat". The great physicist, arguing on thermodynamic principles, speculated whether the breath of an animal, kept a considerable time in a hot bath above the natural temperature of its body, might be found o contain no carbon dioxide at all; possibly even a surplus of oxygen, pointing to an 'unburning' of matter in the body. I hope the physiologists were present at the discussion; one of them, Joseph Barcroft, would certainly have offered to make the experiment on himself. Henry Armstrong, provocative as usual and at considerable length, gave a presidential address to the Section of Educational Science.

It is a very special pleasure to be called to the presidency of the Association in succession to H.R.H. the Duke of Edinburgh, who won the confidence and esteem of scientific people at the meeting last summer, confirmed by many contacts with them since in Canada and the United States and recently in Britain. He presided at the December meeting of the Council, and we told him then how glad we were that these contacts were soon to be extended to Ceylon, Australia and New Zealand. Those hopes, alas, have had to be deferred; and on behalf of the Association I wrote in February to tell him of our deep sympathy in the bereavement which H.M. The Queen and he had suffered. We mourned the loss, not only of a Royal Patron but of one whom all regarded with personal gratitude and affection. I added, and I know you will warmly confirm, that our sorrow and sympathy were accompanied, since we had seen him at work with us, by the certain expectation that the same confident affection will support the Queen and him in the years ahead.

The Duke of Edinburgh concluded his presidential address last year with the words: 'It is clearly our duty as citizens to see that science is used for the benefit of mankind. For, of what use is science if man does not survive?" Here was a challenge to his successor: to discuss how far science has already contributed to human betterment, how far it has provided fresh problems, dangers and difficulties, and to suggest ways in which all who are concerned with science can help, as citizens, to make sure that its results in fact are beneficial.

"As citizens"—for scientists, as such, have no title to superior wisdom or virtue, and outside their special knowledge they are just as likely as others to be misled. The fundamental principle of scientific work is unbending integrity of thought, following the evidence of fact wherever it may lead, within the limits of experimental error and honest mistake. On this there can be no compromise; and since science is a universal interest of mankind, recognizing no barriers of race, class, religion or opinion (provided that is honest), a necessary condition of its advance and application is one of friendliness, frankness and equality. Goodwill and integrity, therefore, are indispensable alike to scientific progress itself and its successful employment for the benefit of mankind. Those who look to scientists as magicians, able to conjure a universal formula out of a hat, may be disappointed to find only so ancient a doctrine: and admittedly, there *is* far more to science than integrity and goodwill. But these are the qualities chiefly required to utilize the opportunities, to resolve the problems and difficulties, which science has provided for present-day society.

The common phrase, "this scientific age", is all too apt to imply, with little justification, that the majority of people, at least in highly developed countries, now think and act scientifically; and, with no justification at all, to suggest that science can replace the older motives of human conduct. It is true that the external circumstances of life have been vastly altered by the applications of scientific discovery and invention, though as yet for only a minority of mankind. The future alone can decide whether natural resources and human ingenuity will prove sufficient, given statesmanship and goodwill, for the same transformation gradually to affect the whole of human society. If not, are stable conditions ultimately possible? Or will there be perpetual conflict between the 'haves' and the 'have-nots'? It is true also that the methods, ideas and results of scientific inquiry have penetrated widely, if not deeply, into popular thinking and belief: the jargon at least of science is widespread, and magic and superstition are gradually losing, if not their currency at least their respectability. Yet such changes may have little real influence on the basic pattern of human behaviour, and, if witches are no longer hunted down and killed, political and racial intolerance can lead to even wilder and crueller excesses. In clearing away old idolatries there is always a danger of allowing new ones to creep in: the unclean spirit went out when the house was swept and garnished, but only to return with seven others more wicked than himself. The improvement of man's estate by the application of scientific knowledge is one of the loftiest of adventures; but a belief that it can be achieved by scientific methods alone, without a moral basis to society, is a perilous illusion. If the methods of human experiment and racial improvement adopted by the Nazis could be regarded purely as applied biology there might be much to say for them. But most of us believe that by abandoning a faith (which has nothing directly to do with science) in the sanctity of the human individual and of moral law they were heading straight for disaster. Yet we shall see later the dilemma in which such scruples put us, in respect of the gravest of all world problems.

The conflict between new knowledge and traditional belief is no novelty. When Eve saw that the Tree of Knowledge was good for food and that it was pleasant to the eyes, and to be desired to make one wise, she took of the fruit thereof and did eat and gave also to Adam and he did eat. This led to their exclusion from the Garden and the warning "in sorrow shalt thou eat of it all the days of thy life". Again and again the attempt has been made to forbid the fruit of scientific knowledge. In 1874 in Belfast, John Tyndall delivered a presidential address to the British Association which provoked a hurricane of controversy: the records tell us that it was denounced from every pulpit in the city. Yet, reading it now, one is impressed not only by its courage but also by its reasonableness. It is true that he claimed that science will wrest from theology the entire domain of cosmological theory, whether of living or of non-living things; but he had previously referred to the immovable basis of the religious sentiment in human nature, bringing as he said "completeness and dignity to man". The views of Lucretius and Bruno, Darwin and Spencer, might be wrong: whether right or wrong, he insisted, we claim the right to discuss them. If to-day I claim the right to discuss not only the scientific facts themselves but also their consequences in human affairs I doubt whether denunciation will follow: if it does, I shall be sorry but unrepentant.

The development which has brought most vividly to the public conscience to-day the ethical problems aroused by the advance of scientific knowledge lies in the field of nuclear physics; and groups of scientific people in the free countries of the world are vigorously debating its various consequences, among them particularly the secrecy attached to weapons as new and devastating as those provided by nuclear fission. Atomic physics, however, is only one of many scientific developments which have brought, or are bringing, a mixture of possible good and evil about which judgments of relative value must be formed; we must not get too excited about one of them. There is no secrecy about most of these developments—they occur gradually and continuously before our eyes, and we tend to accept them without question as though they were natural phenomena; yet, in fact, the consequences of one of them provide the most solemn problem in the world. The dilemma is this. All the impulses of decent humanity, all the dictates of religion and all the traditions of medicine insist that suffering should be relieved, curable disease cured, preventable disease prevented. The obligation is regarded as unconditional: it is not permitted to argue that the suffering is due to folly, that the children are not wanted, that the patient's family would be happier if he died. All that may be so; but to accept it as a guide to action would lead to a degradation of standards of humanity by which civilization would be permanently and indefinitely poorer. Conduct usually falls short of principles; but that would be the worst reason for abandoning principles altogether.

In many parts of the world advances in public health, improved sanitation, the avoidance of epidemics, the fighting of insect-borne disease, the lowering of infantile death-rates and a prolongation of the span of life have led to a vast increase of population. Not only is the population increasing, but also in many places its rate of increase is still rising; and these processes will take so long to reverse that for many years to come the shortage of natural resources, particularly of food, is bound to provide increasing deprivation and disturbance. That provides the practical motive of the Colombo Plan. In India, a Government Planning Commission, in a report of July 1951 entitled "The First Five Year Plan", has dared to face the facts. A doubling in the past thirty years of the survival-rate (births minus deaths) has led to a rate of increase of nearly 1¼ per cent a year, a total of 5 million every year in a population of 360 million.

"With all the effort that the First Five Year Plan will represent, it will be possible barely to restore by 1955–1956 the pre-war standards in regard to food and clothing. Increasing pressure of population on natural resources retards economic progress and limits seriously the rate of extension of social services so essential to civilized existence."

The pre-war standard, in fact, was very poor; much of the population existed below the level of a decent life, scores of millions only just above that of famine. Yet the gigantic national effort proposed in the Five Year Plan, even if successful, may only just resto that miserable standard. Can it sustain it then if t rate of population increase continues ? It is easy answer that a higher standard of life has led in oth countries to a gradually falling birth-rate; but higher standard requires a far greater charge natural resources of all kinds, which cannot be m until the pressure of population is reduced.

In the meantime there is more than danger th the emergency will result in an over-use of natur resources, leading by land erosion, deforestation an other factors to permanent and irretrievable loss this has happened already, and is visibly happenin now, in many parts of the world. In a special secti on "Family Planning" the Indian report recogniz that "an alteration in population trends takes least a few generations to materialize"; and ste are suggested for the education of public opinion the need for limitation, and for experimental effor to be made in the application of simple methods birth control. For its wisdom and courage in ackno ledging the gravity of the situation the India Planning Commission deserves every support; b the problem itself has not begun to be solved, an its consequences will dominate the development India for many years. Indeed, its gravity will co tinue to increase. Malaria is admitted by the Plannin Commission to take an annual toll of a million live and tuberculosis of half a million. The resolute us of insecticides and anti-malarial drugs could soo reduce the former to a small fraction; tuberculos is bound to require more effort and a longer ter Nobody would dare to say that steps to combat thes diseases, and others such as cholera, to improve rur and industrial health, to increase the supply of drug and medical equipment and services, should not b taken on the highest priority: but the consequenc must be faced that a further increase of a millio people a year would result. Thus science, biological medical, chemical and engineering, applied for motive of decent humanity entirely beyond reproach, wit no objectionable secrecy, has led to a problem of th utmost public gravity which will require all th resources of science, humanity and statesmanship fo its solution.

The example of India has been taken because o the sheer magnitude of the problem and because it seriousness is now admitted by humane and responsible men; but the same conditions exist already i many parts of the world and will soon exist elsewher It is *not* a question only of food; if a higher standar of life is to become universal, with education, communications, housing, reasonable amenities an public health, a far greater demand will be made o all such natural resources as power, chemical minerals, metals, water and wood. One is left wondering how long these can possibly take the strai Could world supplies conceivably hold out if th present requirement per head, in the United State were multiplied in proportion to meet the sam demand everywhere—even without any increase present population; and if so, for how long ? The is much discussion of human rights. At what lev can these be reasonably pitched ? And do they exten to unlimited reproduction, with a consequent obligation falling on those more careful ? These problem must be faced not only with goodwill and humanit but also with integrity and courage, not refusing t recognize the compulsion of simple arithmetic. It i right that the scientific imagination should be allowe to play sometimes with the more distant future vhen possibly new methods and resources may be ound to solve all problems ; but only on condition hat our minds are not deflected from the urgent ealities of the present.

By vast improvements in communications, which ave made the world so small, applied science has een one of the chief agents in the present ferment f social, political and economic thought. Can one rge, after the event, that the application was a nistake and that the majority of mankind could etter have remained isolated and in ignorance ? By naking world war technically possible, applied science as helped to stir up national ambitions and social evolutions which, if poverty and deficiency continue vithout hope, may lead to major world catastrophe. hould we therefore refuse to employ science in lefence of liberty and resign ourselves to a universal olice state where no scruples are permitted ? Are ve, in scientific research, to say that some subjects nay be investigated, but not others for fear of the onsequences ? Who then is to decide and by what nternational authority ? And is it practical to insist hat all scientific knowledge should be fully and penly disclosed, without secrecy or reservation of ny kind, military or industrial ? These are problems vhich cannot be solved by rhetoric, or by any simple ormula. The purpose of setting them out is to make lear that we must face them with honesty and ourage ; for they will not solve themselves.

I have led you to the ethical dilemma which perlexes many of us by taking an example in which ew would question either the motives of those who nade the original discoveries, or the humanity of heir application ; or indeed could wish that the fruit f the Tree of Knowledge had been left untried. It s easy to say now that, side by side with the control f disease, there should have been an equal and arallel effort in education, particularly the education f women as responsible citizens ; for there is no ossibility, if women remain ignorant and illiterate, f intelligent widespread family planning and control. But education alone would not have been enough, r indeed possible itself, without a substantial measure f material and social betterment ; and the expense nd effort involved in this would have been indefinitely greater than in the application of medicine and ygiene, which after all has been relatively cheap. Had it been possible to foresee the enormous success f this application, would humane people have agreed hat it could better have been held back, to keep in step with other parallel progress, so that development ould be planned and orderly ? Some might say yes, aking the purely biological view that if men will reed like rabbits they must be allowed to die like abbits, until gradually improving education and the lemand for a higher standard of life teach them better. Most people would still say no. But suppose it were ertain now that the pressure of increasing population, incontrolled by disease, would lead not only to widespread exhaustion of the soil and of other capital esources but also to continuing and increasing interational tension and disorder, making it hard for ivilization itself to survive : Would the majority of umane and reasonable people then change their ninds ? If ethical principles deny our right to do vil in order that good may come, are we justified in loing good when the foreseeable consequence is evil ?

I remember asking an eminent Indian who had aken part in drawing up the so-called Bombay Plan f 1944 why there was no mention of the gravest roblem of all, overgrowing population ; he replied that his colleagues and he had indeed discussed it, but had decided to leave it to God. To a biologist aware of the methods by which animal population is in fact controlled by Nature, this seemed pretty poor comfort ; yet there are many who really take that view, admittedly with the element of reason that we never can be sure that things may not turn up to make all our calculations wrong. Should we then just continue to do the good we see in front of us, in confidence that if our motives are humane, good and not evil will finally result ? Or, taking that rather easy course, are we not showing a lack of the fundamental virtues of courage and integrity ?

The dilemma is a real one, and cannot be resolved by any simple expedient. In another form it is perplexing many of those who are concerned with the development of nuclear physics, the ultimate service of which may be very great, possibly essential if our present type of civilization is to continue when other sources of power dry up ; while the benefits to medicine and industry are already substantial. *But*—nuclear fission has released the threat of unprecedented violence, with the possible destruction of many millions of lives and the accumulated treasures, moral and material, of civilization. The individual conscience may tell a man to have no part in it : that is easy enough, for there are plenty of other interesting things to do, but it does not solve the problem. Moreover, it is possible that defensive weapons, based on nuclear fission, but not of the type intended for mass destruction, can be developed which would make armed aggression intolerably costly. What then of the abolition of secrecy ? In principle, yes, for the historic and unique contribution of science to international goodwill has been in sharing knowledge regardless of race and frontier, and the chief satisfaction of scientific work, the condition of its fruitful development, is frank and free discussion. "Cast thy bread upon the waters, for thou shalt find it after many days" is wise and acceptable counsel in dealing with scientific knowledge ; while "he that observeth the wind shall not sow and he that regardeth the clouds shall not reap" is as aptly applied to human relations as to agriculture. Every possible endeavour, therefore, should be made towards international agreement on sharing scientific and technical knowledge and controlling nuclear weapons ; but this, like peace itself, is a concern of every citizen, not only of scientific people. It is hard enough to get international agreement in quite simple matters, such as the perilous state of the north European fisheries, where no secrecy is involved and little national prestige, and the scientific evidence is unequivocal ; but we must go on trying.

Much scientific and technical advance has led to unexpected dangers and difficulties. Without our present knowledge of bacteriology and preventive medicine, gigantic armies could never be kept in the field, and land war on the recent scale would be impossible. Is medical science, therefore, to be blamed for twentieth-century war ? The indiscriminate use of insecticides, by upsetting the balance of Nature, can quickly do more harm than good. Radio communication may be used for spreading lies and disorder as well as truth and goodwill. Developments in microbiology, in many ways beneficent, may be used in the future for biological warfare, with effects at present unpredictable ; and control by international agreement and inspection might be very difficult. The list need not be multiplied, for all are aware that every new benefit to mankind provides also its own dangers, either as unexpected consequences or by deliberate misuse. Science is not alone in this: liberty may lead to licence, religion can be used to inflame passions, and laws can be exploited to protect wrongdoing. If men of science feel called upon to examine their consciences, so much the better; but they need not imagine that in this they are exceptional.

It has been debated whether "the scientific mind is fundamentally amoral". The real answer is that there is no such a thing as "*the* scientific mind". Scientists, for the most part, are quite ordinary folk. In their particular scientific jobs they have developed a habit of critical examination, but this does not save them from wishful thinking in ordinary affairs, or sometimes even from misrepresentation and falsehood when their emotions or prejudices are strongly enough moved. Their minds are no more amoral than those of surgeons, lawyers, or scholars. As investigators, most of them realize that their function would be stultified were they to introduce moral data into a scientific argument. A surgeon is not required, or indeed allowed, to consider whether it would be better for the world if his patient died under the operation; he has only to carry it out with skill, care and integrity. But it would be foolish to conclude that the surgical mind is amoral. The surgeon himself, as a human being, has to make moral judgments, but he does so outside the operating theatre. So it is with scientific people; like all good citizens they must take account of ethical considerations, and the chief of these, as with other good citizens, are of integrity, courage and goodwill. Integrity forbids them to allow feelings of any kind to obscure facts, but that does not make them amoral; after all, integrity is the first condition of morality.

In the practical world of to-day, complete abandonment of secrecy, in government and industry, is out of the question. The advantages to international relations, and to general scientific progress, of the greatest possible freedom are evident; to these can be added the impossibility, in a free democracy, of keeping the best people unless the conditions of their work are congenial. If scientific men consistently avoid jobs which seem to them to fall short of reasonable freedom, they will force changes of organization so that only necessary secrecy is maintained. The penalty of filling an organization, governmental or industrial, with second-rate people, cheerfully amenable to unnecessary restrictions, is far too evident in its result on efficiency to be tolerable for long. The cure, therefore, is largely in scientists' own hands. In this, as in many other aspects of their work, moral considerations come in, and the only way to resolve the dilemma which is in so many minds is to discuss it frankly. To neglect it altogether is not amoral but immoral; it is the duty of all of us as citizens to consider the ethical basis of our work.

To-day, when the public importance of science and its popular esteem may turn some people's heads, it is well that scientists should realize that the prestige of science is not their personal property, but a trust which they have an obligation to pass on uncompromised to their successors. The popularizing of genuine science is an important public service, and we should all be ready to take our part in it according to our powers; but to use the general prestige of science as a bait to attract attention to pronouncements on other topics, for example, on politics or religion, is a disservice both to science and the public. As a citizen I need no more justification than any other citizen in saying what I like about such things; but I have no right to pose as a representative of science in discussing them. In the days when the representatives of religion claimed supernatural knowledge of the natural world, it was necessary to insist, as Tyndall did, that the natural world belongs to science. Fortunately those days are past. If they now claim that the facts and trends of over-population are not what we say, we can argue about that as a scientific question: but if they insist that its consequences should be left to God, they must allow us as citizens to take the opposite view. If political pressure were applied in any way to force conformity to particular scientific theories, as happened in Germany and is happening now elsewhere, then one's right and indeed one's duty would be clear, alike as citizen and as scientist. But the nature of political institutions and the policies of political parties are not scientific questions, and how I choose to vote has nothing to do with science. Indeed, curious as it may seem, the spectrum of political opinion of scientists in Britain is much the same as that of other similar groups: though the loudspeakers are generally tuned in to one particular wave-band.

Some seventeen hundred years ago there crystallized out, from many centuries of experience of the human problems and ethical necessities of medicine, the so-called Hippocratic Oath. The obligation of integrity and trust; the insistent claim of suffering; the care of mothers and children; solicitude for the old and weak; the sanctity of human life: these are as vital a part of medical tradition as its science and its art. Practice, it is true, may lag behind principles, but at least such failure is regarded as discreditable; and it is hard to imagine any kind of civilization in which the ethical principles of medicine were generally disregarded. That is one reason why the future possibility of biological warfare is particularly repugnant. To-day science finds itself, unexpectedly and without those centuries of tradition and experience, in a position no less important to the community than medicine; and its ethical principles have not yet clearly emerged.

Every candidate for admission to the earliest of American learned associations was required to answer yes to the question: "Do you love truth for truth's sake, and will you endeavour impartially to find . . . it for yourself and communicate it to others?" That affirmation might have its place in a modern scientific version of the Hippocratic Oath. But again the same dilemma arises—"endeavour impartially . . . to communicate it to others". Apart altogether from considerations of national security, in many fields to-day much of the best research is done, and done increasingly, in industrial laboratories. Those who have seen and admired such work, and the people who do it, cannot but applaud the foresight which made it possible. But if all the results are to be communicated at once and impartially to others, could directors and shareholders be reasonably expected to continue their support? Indeed, if an industry were nationalized, could it afford to give away its secrets to competitors abroad? Not in any real world, in which a nation must remain solvent and industry must depend for success on the rapid application of new knowledge. The dilemma must be met by reasonable compromise, of which perhaps the most hopeful sign to-day is that many of the directors of industry come up through research departments. A friendly and familiar contact between management and research, and between industrial nd outside scientific workers, can reduce this articular dilemma to manageable size.

A graver problem is provided by research under overnment, when considerations of security come in. n the emergency which became evident in 1935, the ecret development of radar for purposes of air lefence aroused no obvious pangs of conscience; and nany other developments come in that class. But he surest of military maxims is that counter-attack s an essential part of defence; to limit scientific nethods to defensive weapons would be to ensure lefeat, indeed it is quite impracticable. But let us e realists; so long as offensive weapons may be sed, the part played by the scientist is no more mmoral than that of the engineer, the workman, the oldier or the statesman, and the attitude of 'holier-han-thou' is unbecoming. We all bear, as citizens, n equal responsibility. But is it practical to suggest hat all scientists in all countries should agree, and nold to their agreement whatever happens, to take no part in research on offensive weapons? Or at least should they endeavour impartially to communicate its results to others? The answer is evident. There are individuals in all free countries who find such work intolerable. In those countries their scruples are respected, and they are at liberty to do something else; but let them not imagine that the problem is solved that way, or that those who think otherwise are necessarily stupid or immoral. The first condition of freedom is freedom of conscience, and the scientist has the same right to that as any citizen: but freedom does not extend to giving away other people's property, whether of goods or knowledge.

There seems to be no simple answer to the riddle. All knowledge, not only that of the natural world, can be used for evil as well as good; and in all ages there continue to be people who think that its fruit should be forbidden. Does the future welfare, therefore, of mankind depend on a refusal of science and a more intensive study of the Sermon on the Mount? There are others who hold the contrary opinion, that more and more of science and its applications alone can bring prosperity and happiness to men. Both of these extreme views seem to me entirely wrong—though the second is the more perilous, as more likely to be commonly accepted. The so-called conflict between science and religion is usually about words, too often the words of their unbalanced advocates: the reality lies somewhere in between. "Completeness and dignity", to use Tyndall's phrase, are brought to man by three main channels: first by the religious sentiment and its embodiment in ethical principles, secondly by the influence of what is beautiful in nature, human personality or art, and thirdly by the pursuit of scientific truth and its resolute use in improving human life. Some suppose that religion and beauty are incompatible, and others that the æsthetic has no relation to the scientific sense; both seem to me just as mistaken as those who hold that the scientific and the religious spirit are necessarily opposed. Co-operation is required, not conflict: for science can be used to express and apply the principles of ethics, and those principles themselves can guide the behaviour of scientific men; while the appreciation of what is good and beautiful can provide to both a vision of encouragement.

Is there really, then, any special ethical dilemma which we scientific men, as distinct from other people, have to meet? I think not: unless it be to convince ourselves humbly that we are just like others in having moral issues to face. It is true that integrity of thought is the absolute condition of our work, and that judgments of value must never be allowed to deflect our judgments of fact. But in this we are not unique. It is true that scientific research has opened up the possibility of unprecedented good, or unlimited harm, for mankind; but the use that is made of it depends in the end on the moral judgments of the whole community of men. It is totally impossible now to reverse the process of discovery: it will certainly go on. To help to guide its use aright is not a scientific dilemma, but the honourable and compelling duty of a good citizen.

SUMMARIES OF ADDRESSES OF PRESIDENTS OF SECTIONS

CONTRIBUTORS TO EXPERIMENTAL PHYSICS FROM BRITAIN

PROF. A. M. TYNDALL'S presidential address to Section A (Mathematics and Physics) deals in the main with some contributions by workers in Great Britain to experimental physics. His selection of topics has been made to illustrate the citation of the recent award of the Nobel Prize to Prof. C. F. Powell, expressed in the following words: "His special claim to consideration is, in my view, the fact that he has shown that discoveries of fundamental importance can still be made with the simplest apparatus".

The reason for quoting from this occasion is that the words emphasize an approach to the field of experiment which is characteristic of much British physics and following the great scientific tradition of the nation. Examples are common in the literature of simple experiments which have opened up large fields for discovery. After giving examples from the work of Rayleigh, Boys and Chattock, Prof. Tyndall refers to simple experiments which have been fundamental to the development of the items of the main sectional programme of the meeting: the work of the Cavendish Laboratory in the days of 'sealing wax and string', which forms the root of the discussion this year on electrical discharge in gases; and the simple adaptation to radio of the principle of Lloyd's fringes, by which Appleton initiated not only the exploration of the ionosphere but the fields of radio-meteorology and radio-astronomy. Again, ever since Sorby first studied microscopically the surface of opaque solids, Great Britain has contributed widely to the study of their physical properties. A recent example is that of the theoretical work of Frank on the growth of crystals by condensation of atoms on the step of a screw dislocation, and its experimental confirmation by Griffin and others by photographs of crystal surfaces.

But the best modern example of the consequences of a simple idea comes from the field of nuclear physics. Though much has been written on Britain's past contributions to nuclear physics, less has been said of the fact that it still leads the world in the study of processes of the highest energy. This has followed from the simple device of exposing a photographic emulsion to cosmic rays, first at high mountain altitudes and later from balloons. This technique at Bristol, and cloud-chamber investigations from Manchester, have been responsible for the great majority of the important discoveries in nuclear processes of high energy since the Second World War. A number of new types of particle of short life have been discovered, all but one of them in Britain. By a study of their modes of decay, complexity is beginning to give way to order in the phenomena disclosed.

The great machines of the world, absorbing millions of pounds of money, are now studying under controlled conditions the properties of π-mesons discovered by tracks in a photographic emulsion exposed to cosmic rays at mountain altitude. Meanwhile, with the aid of balloons, particles of energy two thousand times greater than anything so far attainable in a laboratory are under observation. It is therefore important to regard this work as part of the larger programme, so that funds, relatively small in amount, continue to be available for its prosecution and extension.

THE ADVANCING FRONT OF CHEMISTRY

THE pace of scientific, social and economic changes in modern times is unprecedentedly rapid. Thus, as Prof. W. Wardlaw points out in his presidential address to Section B (Chemistry), it is easy to understand why the pace of the science of chemistry is growing ever faster and faster. In the past quarter of a century, the number of investigators in both pure and applied chemistry has increased enormously, while research itself is more adequately financed and to some extent better organized than ever before. It is tempting but not very profitable to try to imagine what will have been accomplished, say, fifty years hence, if this acceleration continues. Chemists may well consider that the pace of advance may be such that no human mind will be able to correlate into any significant whole the enormous accumulation of chemical facts. Yet man's curiosity about the universe and his own complex self will most probably increase, and the astonishing growth of the science of chemistry will continue. At intervals during the past half-century prophets have confidently predicted the demise of inorganic chemistry and even of organic chemistry. Chemistry, however, has confounded the prophets by its amazing vitality.

The award of the Nobel Prize for Chemistry for 1951 to McMillan and Seaborg directed the attention of the whole scientific world to the most spectacular advance made in chemistry for a long time: the extension of the Periodic System from element 92 (uranium) to element 98 (californium). Particularly important in this work was the development of ultramicrochemical methods of analysis, which enabled the chemistry of the trans-uranium elements, usually available in millionths of a gram, to be investigated. The combined discoveries of the physicist McMillan and the chemist Seaborg and their associates have opened whole new fields for the investigator interested in the realm of inorganic chemistry.

Chemistry already has made an indispensable contribution to atomic energy research and development, and chemists will fill a major role in establishing nuclear power as a benefit to humanity. The next phase in the development of atomic power probably depends more on new materials than on any discovery in nuclear physics or improvement in atomic technology. This extension of technological interest in new materials, all over the world, is bound to emphasize the need for broadening our knowledge of both the familiar and unfamiliar elements and compounds. It is surprising how little we know about many of the chemical elements, even the metals. We know still less about certain elements which lie midway between the metals and the non-metals, the so-called metalloids. A host of new researches has been set in motion primarily by the needs of the atomic energy programme. However, the results will be the starting-point of new developments in every phase of industry. In the United States, there is a great revival of interest in inorganic chemistry, and in Britain there are signs that its value and importance are being increasingly realized.

During the past decade, most people have had an uneasy feeling that all is not well with their food. As we all know, the food processor has chemicals for every need—preservatives, emulsifiers, colouring agents, etc. Some idea of the magnitude of this problem of chemicals in food can be obtained from the report of the Delaney Committee set up in June 1950 by the United States Congress. The Committee heard the striking evidence from the officers of the Food and Drug Administration that 704 extraneous substances were thought to be in use. Of these, only 428 were considered harmless as normally employed, leaving 276 of which the safety was open to question. There is little doubt that the wide publicity which this subject is receiving will call for planned administrative action in the United Kingdom.

GEOLOGICAL RESEARCH AND ITS APPLICATIONS

FOR his presidential address to Section C (Geology), Dr. J. E. Richey takes as his subject "Some Aspects of Geological Research and their Practical Application". Quoting a remark made by Henri Poincaré in "La Science et l'hypothèse" that "Science is built of facts, as a house is built of stones; but an accumulation of facts is no more a science than a heap of stones is a house", Dr. Richey has selected a number of classic examples of geological research as illustrations of the methods employed in building the 'geological house'. The investigations chosen are mainly from Great Britain and range from those of James Hutton and William Smith to the present day. From an analysis of these and of the criteria used in each case, a definite pattern of evidence which led to the particular conclusion can be adduced. Dr. Richey sets out the various types of proof-pattern made use of under the following headings: anomalies in observed data; similarity and dissimilarity of occurrences; analogy; repetitive evidence; geometrical patterns of evidence; and intersection of different lines of evidence. Examples of each type of proof-pattern are given.

Dr. Richey then deals with practical applications of geology. It is especially emphasized that economic geology is not a subject apart from pure geology but is simply geology applied to a variety of objectives containing an economic purpose. Particular subdivisions considered are coalfield research, the search for oil, the location of ore deposits, and civil engineering problems. In each case one or more examples are given in illustration of the main patterns of evidence involved. These include the discovery of e Kent Coalfield, the guiding idea of Godwin-usten being based upon geometry on the grand ale ; in oil geology, the use made of geometrical atterns exemplified by the anticline of Bahrein land in the Persian Gulf, mapped by G. E. Pilgrim, d by the recently investigated dense fissured limeones of Venezuela, with a reference to the value of alæogeography in the search for new fields ; in ore ology, again with geometrical patterns dominant the varied types of fracture zones in American re-fields, and the recent mineralogical research on e hydro-thermal 'plumbing system' of East Tintic Utah by T. S. Lovering ; in civil engineering, the ocation of the Vrynwy dam-site in North Wales hich followed from the pursuit of a scientific idea y an engineer, Dr. G. F. Deacon, and the investiations by Prof. P. G. H. Boswell which preceded the riving of the Mersey vehicular tunnel at Liverpool, n example of the use of converging lines of evidence.

In conclusion, a few words are added concerning e investigator himself, the capacity inherent in the uman mind of creating 'newness', and the overuling need for self-criticism in the search for truth.

SOME PROBLEMS OF PARTHENOGENESIS

N his presidential address to Section D (Zoology), Prof. A. D. Peacock is reviewing the more imortant researches of the past twenty years on animal arthenogenesis and indicates their bearing on ertain fundamental biological questions. Parthenoenetic phenomena have recently been recorded in everal large groups previously not known, or ubiously known, to be parthenogenetic. The only ain groups in which such phenomena are unknown re Protozoa, sponges, ascidians and reptiles, but the dications are that parthenogenesis, if only rudientary, is more common than generally supposed. f great interest is Muldal's discovery of obligatory arthenogenesis in four genera of earthworms, cultative parthenogenesis in a fifth genus, and the olyploidy of the species concerned. Records and etails of geographical parthenogenesis increase, eiler's work on *Solenobia* moths and Suomalainen's n weevils being particularly striking. Each worker as shown independently the appearance of polyploid arthenogenetic races since the Quaternary ice eriod and their colonization of high-altitude inhositable places, the ancestral diploid bisexual race emaining in the lower and warmer regions.

In cyclic parthenogenesis, for example in rotifers d waterfleas, there exists heterogony, the alterntion of the bisexual and parthenogenetic modes of production, and much discussion has centred ound the problem of how the cycle of events is etermined, whether by hereditary or by environental factors. The recent work on rotifers by Hans uchner and on waterfleas by Madeleine von Dehn, sing the most refined techniques, amply confirms revious views that environmental factors determine e cycle and, further, shows that the main factor is e quality of food. Buchner also finds an inherent aximum potentiality for bisexuality (*Reaktionsorm*) in individual races of rotifers and that the level bisexuality attained in a race at a given time epends upon the strength of the environmental ctors.

On parthenogenesis and sex, one problem is that male production from unfertilized and haploid eggs as seen in the honey bee and Hymenoptera generally, also in rotifers and certain other forms, the phenomenon being unexplained by the classical theory of genic balance. In Whiting's theory of multiple alleles is found the best solution. It is based on genetical evidence. A sex segment on each of two homologous chromosomes of the diploid female exists in nine different alleles ; the diploid female possesses two unlike alleles and is heterozygous ; the diploid male, a rare phenomenon arising from certain pairings, has two like sex alleles and is homozygous ; and the functional male arising from an unfertilized egg therefore carries only one sex allele and is azygous. Another problem regarding sex arises out of Seiler's intersexual *Solenobia* moths, which individually are shown *inter alia* to possess the same grade of intersexuality in all their organs. Seiler's interpretation is that his specimens possess a fixed grade of intersexuality from the embryo onwards, which conflicts with Goldschmidt's earlier time-law (*Zeitgesetz*) interpretation, based on his gipsy moth intersexes, that there is a switch-over from one sex to the other during development.

Early experiments by Loeb, Bataillon, R. S. Lillie and others on artificial parthenogenesis stimulated research on fundamental problems of reproduction, development and cell physiology. More recent work by the Runnström school, Tyler, Rothschild and others, has focused attention on the problem of the artificial and natural activation of the unfertilized egg. Remarkable successes have been obtained by Pincus and co-workers on mammalian parthenogenesis ; they have obtained seven rabbit parthenogones, some alive, from eggs artificially stimulated *in vitro* and then transplanted into rabbit foster mothers. The regulation processes of the parthenogenetized eggs of rabbits as studied by Pincus, and of rabbit, sheep and rat, as worked out by Thibault, also receive attention. Other aspects treated comprise the extent and evolution of parthenogenesis and its role in reproduction and evolution ; suggestions for researches suitable for biologists of all kinds ; and the possible bearing of artificial parthenogenesis on human affairs.

ASPECTS OF SETTLEMENT IN THE OVERSEAS DOMINIONS

PROF. R. O. BUCHANAN's address to Section E (Geography) is a broad comparative survey of some historical conditions that controlled the process of the taking possession of land in areas of modern colonization. This process was spread over two centuries and a half, from the founding of the Dutch East India Company's settlement at the Cape in 1652 to the occupation of the Canadian prairies, which began at the close of the nineteenth century. The Dutch expansion eastwards from Cape Town took place before the Industrial Revolution, while the corresponding movement in Australia, New Zealand and the prairies of Canada reflected the differences in outlook and in material circumstances progressively produced by that revolution. In South Africa the official policy for a century and a half was that of the Dutch East India Company, conceived purely in the interests of its trading activities in the East Indies. In Australia in the earlier stages official policy was that of the Colonial Office. In New Zealand settlement was organized by colonization companies from 1840 onwards, and official policy was the policy of these companies as agreed by the Colonial Office. In both Australia and New Zealand that policy was dominated from 1830 by the views of Edmund Gibbon Wakefield and his supporters.

These two sets of policies, South African and Australasian, though separated in time by a century and a half, were curiously similar in their insistence on small tillage farms in narrowly circumscribed settlements, and consideration is given by Prof. Buchanan to the process by which in all three countries the people on the spot evaded and defeated the cramping control of official regulations, and produced a moving pastoral frontier, in Francis Jackson Turner's sense of the term. This pastoral frontier area has survived only where the natural conditions are difficult, through low rainfall, as in South Africa and Australia, or rugged relief, as in New Zealand.

With the passing of control to the local governments, the more productive area was transformed, mainly through political action, into a farming frontier, with farms of a size capable of providing an acceptable family living, and therefore varying in size with the productivity of the area concerned. Unique to South Africa were the period of slavery and the struggle with the Bantu. The North Island of New Zealand with its Maori wars, born of incompatible usages in land holding, presents a partial analogy, though with significant differences. The settlement of the Canadian prairies differs from that of the southern dominions in coming so late (end of the nineteenth century) and in being so strongly influenced by American precedents. The quarter section of 160 acres for specialized wheat growing was not the final answer to the occupation of the prairies by a permanent agriculture, but it was a good first approximation, and it did solve at one stroke several of the problems that had taken South Africa over two centuries, Australia over one century and New Zealand over half a century to solve. These economic, political and administrative measures have left their imprint on the face of the land in the settled areas, and provide much scope for detailed studies in local historical geography.

FULL EMPLOYMENT IN RETROSPECT

FOR his presidential address to Section F (Economics), Prof. D. T. Jack discusses the problems of full employment.

Pre-war discussions relating to employment policies were conducted against a background of prolonged under-employment, and the main issue concerned the means of attaining continuous full employment through the maintenance of aggregate demand. The emergence of inflation and over-full employment did not appear as a pressing possibility. Similarly, at the end of the War in 1945, there was a widespread expectation that the experience of the years following 1918 would repeat itself and that in order to prevent a recurrence of substantial unemployment special efforts would be required to ensure that aggregate demand did not display symptoms of chronic deficiency. These expectations have not been realized, and in fact our main problem, which has not been adequately solved, has been precisely the development of inflationary pressures and the phenomenon of over-full employment which were neglected in pre-war discussions.

It is probable that an undue amount of attention is devoted to general movements of prices, wages, etc., and insufficient attention to relative movemen within the same indices. Under conditions of fu employment, relative price and wage movement have a particular importance in allocating resource greater than their importance during periods under-employment. Attempts to suppress th symptoms of inflation do damage to the norm working of the price and wage mechanism.

Consideration is given to the nature and effects these inflationary pressures, the natural distortion in the structure of prices to which they give rise, th further artificial distortions which result from th attempts to suppress the symptoms of the inflationar process, and the recurrence of balance of paymen crises. The view is taken that the appropriate trea ment of these problems lies in the field of domest policy rather than by means of international agre ment. In this connexion reference is made to thr reports by committees of experts set up by th Economic and Social Council of the United Nation which appear to be preoccupied with the proble of maintaining aggregate demand as a means dealing with a situation which had been anticipate but which has not as yet arisen. The recommend tions of these committees have been unduly concerne with economic aggregates and they have had pronounced inflationary bias.

Examination is also made of the tendency for pric inflation to be followed by cost inflation, and in tha connexion particular reference is made to proposal for the construction of a unified wage policy. O general grounds these proposals are not accepted but further consideration is given to the suggestio that wages should be related to productivity eithe by means of a mechanical link with an index o over-all productivity, or with an index of productivit for the industry in which the wages are paid. Thes proposals are not commended. If the main problem of inflationary pressure can be tackled at its sourc these various devices, apart from their technica awkwardness, become superfluous. The experienc of full employment emphasizes the importance o concentrating on this problem of inflationary pressur for future policy.

PROGRESS IN AERONAUTICAL SCIENCE AND ENGINEERING

IN his presidential address to Section G (Engineering Sir Ben Lockspeiser points out that there has bee a very great advance in aviation since the previou meeting in Belfast of the British Association fift years ago. That occasion preceded the Wrigh brothers' successful achievement of powered flight b one year. Yet aeronautical progress has been suc that last year nearly one-third of all the person crossing the North Atlantic went by air. It is significant that the Wrights found it necessary to inven the wind tunnel and other techniques which no belong to the science of aerodynamics before the managed to engineer their first aeroplane. Aeronautical science and engineering have gone hand i hand in the evolution from the aeroplane which wa a wooden skeleton to the stream-lined metal monoplane built of hollow shells in aluminium alloy.

The modern aeroplane has 'clean' lines: th external struts, bracing wires, undercarriage, etc. are no longer seen. These parts contribute nothin to the lift and are a liability on the engine. However aerodynamic cleanliness means more than the absenc unnecessary projecting parts. The stream-lines llow the surface and wasteful eddying is at a minium. The lift-induced drag is inescapable, but is not e main contributor to the resistance in high-speed ght. For speeds of less than, say, 500 m.p.h. the maining and larger portion of the drag is due to scous effects. Much would be saved if the flow in e boundary layer next to the surface could be made minar instead of turbulent.

The conditions for boundary-layer flow, which is ainly laminar, are very exacting. The brilliant athematics of S. Goldstein and others has led to itable designs, but the surface must have the noothness of writing-paper and be almost free from aviness. Even then, it has been found in flight tests 'laminar-flow wings' that dust particles and insects icked up at low altitude may promote the onset of rbulence in the boundary layer.

At speeds about 70 per cent of the speed of sound, is no longer possible to regard the air as an incomessible fluid. The air is accelerated in its passage ver the curved surface of an aerofoil, and the local elocity of sound is exceeded long before the aircraft self reaches sonic speed. Shock waves then occur the downstream ends of the regions of supersonic ow, and their formation is accompanied by a great icrease in drag. The movement of shock-waves the 'transonic' range of speeds leads to movement f the centre of pressure and consequently affects the quilibrium of aircraft and throws up problems of ontrol and stability. At supersonic speeds a bowave is formed, and the flow becomes stable with no rious change of the centre of pressure as the speed r incidence is varied. The onset of shock-waves at igh subsonic speeds may be delayed by reducing the cceleration produced by curvature; for example, y making the wings thin. The velocity component the direction of maximum wing surface curvature ay be reduced by sweepback. This solution has arked benefits, but they disappear at high superonic speeds.

The efficiency of the conventional combination of ngine and propeller falls at high speed, as the proeller—like the wing—is beset with 'compressibility' rag. The thrust necessary for transonic flight is now otained by the combination of gas turbine and jet ipe, namely, the turbo-jet. This type of engine develops more thrust per unit of frontal area than any her type of air-consuming engine, but it may be condered to be still in its infancy. At sufficiently high personic speeds the pressure at the air intake is high nough to obviate the need for a compressor, and ence also to make the turbine superfluous. This is the rinciple of the ram jet—an engine without moving arts. Another type of power unit for use in special rcumstances is the rocket, the characteristic feature which is that the oxygen for combustion is selfontained within the fuel.

The development of light alloys of high strength as had much to do with the progress of aircraft ructures, which themselves are characteristically ifferent from any other. Considerations of strength, iffness and fatigue properties at a minimum cost in eight decide the design. High flying speeds have volved high landing and take-off speeds, with the onsequent replacement of landing fields by vast reas of concrete. Some revolutionary ideas to bviate the need for these are now being studied. he use of flying-boats and further application of the elicopter principle are other possibilities. The future the air may well lie in the conquest of the ground.

ARCHÆOLOGY, FOLKLORE AND SACRED TRADITION

THE presidential address by Prof. E. O. James to Section H (Anthropology) traces the relation of archæology to sacred traditions. With the advance in knowledge and in the changed intellectual climate and social environment of to-day, the modification in the earlier evolutionary approach to the study of man is most apparent in the cultural aspects of anthropology. It is now widely recognized that so many factors have been evolved in the origin and development of human institutions and techniques, social structures and religious traditions that clearly defined unilineal systems of development cannot be maintained in relation either to the archæological evidence or to the underlying modes of life, belief and organization. Thus, the distribution and correlation of the palæolithic cultures in different parts of the world suggest that widespread movements of peoples and diffusion of techniques and ideas played an important part in the process of development, though not to the exclusion of independent invention and the influence of local conditions. In more advanced states of culture this is increasingly apparent.

With the arrival in Europe of the Crô-Magnons, and the groups of *Homo sapiens* allied to them, cultural progress became more rapid and complex, and among the achievements in the later stages of the last glaciation was the emergence of a sacred tradition. Its beginnings can be detected in the Mousterian ceremonial interments, it is true, but it was not until the Upper Palæolithic that a cultus began to find expression not only in respect of the disposal of the dead but also in the fertility emblems, commonly known as 'Venuses', and in the art of the decorated caves. To a sanctuary like Altamira, Lascaux or Cogul, recourse seems to have been made by generation after generation of hunters to control the chase by supernatural aid, to stimulate the propagation of the species on which they relied for their food supply, and to establish a mystic bond with providential sources of life and abundance.

When this sacred tradition became a spent force at the end of the Palæolithic (that is, in the Mesolithic), in due course, after the rise of husbandry and herding in the Ancient East and the subsequent diffusion of neolithic settlers from the third millennium onwards, its place was taken by a megalithic cultus distributed along the Mediterranean and Atlantic littoral to Brittany, the British Isles and the shores of the Baltic, with extensions through southern France to Sweden and in an easterly direction to India and Polynesia. Here, again, certain sacred enclosures (for example, Avebury, Carnac, Bethel and the *topes* at Sanchi in India), associated with holy persons or relics and transformed into a *locus religiosus*, became centres of pilgrimage and developed a cultus which persisted throughout the ages. Although all these sites and their rites were not generically connected and the product of a 'megalithic race', they cannot have been independently evolved in complete isolation from each other. On the contrary, as their structure and the legends connected with them indicate, they represent a cultural diffusion spreading from the Mediterranean to Western and North-western Europe. Once it was firmly established in a particular locality, however, the sacred tradition and its cultus have persisted from age to age.

This is illustrated in the long and complex history of the famous medieval shrine of Santiago de Compostela with its maritime legend which, it is contended, was of megalithic origin. In a modified form with different settings, the same tradition has recurred and survived south of the Minho in Portugal, and can be detected in many cult legends throughout the megalithic region (for example, the St. Martha story). Behind this widespread theme and its cultus lie the movements of peoples, for a variety of purposes, and the diffusion of culture, which characterized the rise of Neolithic civilization in the Ancient East, bestowing on certain sites and centres a permanent tradition of sanctity of sufficient endurance to enable pagan sanctuaries to become Christian shrines.

NERVOUS CONTROL OF THE MOVEMENTS OF THE ALIMENTARY CANAL

In his presidential address to Section I (Physiology), Prof. R. C. Garry points out that, in spite of continuing interest and of steady research, our present attitude towards the nervous control of the alimentary canal differs little from that expressed with general acceptance more than fifty years ago by Bayliss and Starling. Yet many facts have since been elicited which appear not to conform to their original conception, and constructive attacks have been made on certain aspects. Nevertheless, for want of a better, we have still to subscribe, more or less, to the original hypothesis.

When entirely separate from the body, the intestine, if kept under suitable conditions, can still show co-ordinated movements. There must be some form of intrinsic control. Certain simple and local movements may be 'myogenic' and independent of the nervous elements in the gut wall. Peristaltic waves, however, may extend over a considerable length of gut, moving only caudad. Bayliss and Starling believed that peristalsis is governed by a reflex in the nervous myenteric plexus of Auerbach. This belief has been vigorously attacked from several sources, but modern work seems once more to emphasize the importance of the nervous element.

Much of the present uncertainty is due to our imperfect knowledge of the histology of the nervous plexuses in the gut wall. Are there receptors in the intestine ? If so, what is their nature and where are they located ? Do axons passing from the gut into the central nervous system make contact with nerve cells in the myenteric plexus ? How many types of nerve cell are present in the wall of the intestine ? How are the outgoing axons from the nervous system to the gut distributed to these nerve cells in the gut ? Until the histologists can give an answer to these questions, we may be unable to interpret satisfactorily the nature of the control of the intrinsic movements of the intestine.

In the intact animal the autonomic nervous system undoubtedly influences the activity of the gut ; and it is attractive to believe that the two divisions of the autonomic system, the orthosympathetic and parasympathetic, oppose one another, as they are known to do elsewhere in the body. Yet there are many observations inconsistent with this view. It may easily be that our experimental approach is crude and is responsible for the observations inconsistent with theory. In spite of everything, the original conception still holds the field, partly due to its inherent logical tidiness and partly to its appea to our preconceived notions.

At the cranial and caudal ends of the gut there i less dubiety. There the alimentary canal seems t lose much of its autonomy and to come mor intimately under the influence of the nervous system The complex acts of swallowing, vomiting an defæcation are undoubtedly governed by elaborat reflexes which control not only movements of the gu but also the behaviour of skeletal musculature.

In the body, the intestine not only receives nerv impulses from the central nervous system, but als sends impulses into the nervous system. Recen work has disentangled the routes followed by thes ingoing nerve impulses, but we still do not kno exactly how and where they arise. Neither do w understand the normal function of these ingoin nerve impulses. They may give rise to sensation, bu apparently only when the normal gives place to th abnormal. Moreover, the controversy concerning th nature of sensation from the viscera is by no mean settled. Once more, only at the extremities of th gut can we form a clear picture of the nature an functions of the impulses which pass inwards int the central nervous system. It may easily be that better understanding of the nature of the nervou control of the intestinal movements will depend no so much on the physiologist as on the histologist an morphologist.

THE ASSESSMENT OF PERSONALITY

PROF. P. E. VERNON, in his presidential addre to Section J (Psychology), discusses "Th Assessment of Personality".

Personality may be regarded as an organized and fairly stable structure which includes all the social and emotional traits, the interests and attitudes and complexes that underlie a person's behaviour. Difficulties in studying it scientifically and assessing it arise, first, because many of its links are repressed into the unconscious mind. Secondly, it is not purely a property of the individual, but varies with the particular social environment. Thirdly, personality traits are generalized inferences from behaviour ; they involve subjective interpretation by an observer, and thus depend largely on the outlook and mentality of the observer and on the interaction of his own personality with that of the individual. Nevertheless, considerable progress has been made in recent years in the theoretical analysis, and in experimental investigations, of personality. But we do not possess, and cannot expect to devise, simple, straightforward tests comparable in reliability and validity to our tests of aptitudes and attainments.

Many experiments show wide discrepancies between the personality judgments of different interviewers, or observers, of the same individuals. In personnel selection work, predictions of vocational or educational suitability, based on interviews of recruits, school pupils or university students, are often poorer than predictions based on a few psychological tests of aptitudes. Some vocational interviewers are relatively successful ; many employers, teachers and psychologists are very unsuccessful. More intensive 'clinical' or psychiatric interviewing, designed to elicit a complete picture of personality structure, may merely result in more biased assessments. Closeness of acquaintanceship also tends to make for greater inaccuracy.

Among the many objective tests that have been ried, physical or physiological indices of temperament for example, somatotypes or the psychogalvanic eflex), and simple tests of perseveration, fluency and ariability are generally unpromising. More realistic ests ituations can be engineered for bringing out uch traits as honesty, persistence, emotional instability and sociability; but these methods are too laborate for selection or guidance purposes. Indirect bservations or measurements of the manner of eacting to various performance or 'stress' tests are nore useful, in skilled hands. The group observational nethods popularized by War Office selection boards re widely applied, and provide a useful extension of he interview. But they are essentially subjective nd greatly dependent on the skill of the observer. o-called projective techniques also involve so much nterpretation that they are almost useless for ocational and educational predictions, though aluable for differential diagnosis of abnormal ersonalities. Personality questionnaires are genuinely seful at a fairly sophisticated level for assessing nterests and social attitudes, and even for measuring ertain social and emotional traits, provided that the uestions are sufficiently disguised—for example, by he 'forced choice' technique—and that the scoring eys are empirically validated. Ordinary personality atings (for example, on pupil record cards) are of ttle value, though a number of techniques have been evised for making more effective use of acquaintances' udgments. The chief difficulty in supplying the sychologist with a useful set of instruments for ersonality assessment is the amount of psychological nd statistical investigation needed, and the shortage f qualified investigators in Britain.

ANATOMY OF METABOLISM IN HIGHER PLANTS

THE full title of the presidential address of Prof. Meirion Thomas to Section K (Botany) is "The natomy of Metabolism in Higher Plants: Total letabolism, Metabolic Processes and Partial Reactions".

The axiom is that transformation of matter and nergy lies at the root of all biological events. Specific every organism, or a component cellular part, is s total metabolism. The physiologist accepts this oncept and abstracts from it metabolic processes or special study. Categories are very mixed in the hapter headings: photosynthesis; respiration; cid, nitrogen or fat metabolism, and so forth. espiration is a traditional term for the absorption f oxygen and a related production of carbon dioxide y a living organ. The gaseous exchange may be an xternal manifestation of an integral internal process, aving a definite beginning and end. Current searches bear on questions concerning the beginning f the process and the integration of events. The utcome of these researches will determine whether r not the traditional term will survive as something nore than a counter with which to reckon. When nalysis and synthesis can proceed no further, the erm may still retain a biological meaning. The rucial point may turn out to be that action is, or is ot, attributable to organization within a visible or nvisible cell structure. The known facts about ertain other processes point to the possibility of irection by organized enzyme complexes. However, the abstractions from total metabolism implied in many chapter headings in current use are plainly made for classificatory convenience. They are artificial and not natural.

Analysis of total metabolism into component fractional processes that still retain their characteristic pattern has not proceeded very far. Worthy progress may, however, be claimed for the study of the ultimate fragments of which abstracted metabolic processes and, consequently, total metabolism, are composed. These fragments are the partial reactions, the physicochemical realities. The elucidation of the functions of key partial reactions will loom increasingly large in the future study of physiology. With the achievement of a correct synthesis from biochemical knowledge about partial reactions, the pattern of a metabolic process would emerge. Ideally, analysis and synthesis would meet in the abstracted process, and we would see in the whole the harmonious working of the parts, relating functional actions, whether single events or blocks of events in a process, to the maintenance of individuals or the perpetuation of a race.

It is asserted that, for higher plants, well-authenticated facts about reaction sequences and linkages are still in very short supply. Problems of intermediate metabolism are stated. Methods used in fact-finding are outlined, and some of their limitations indicated. Detailed treatment is given to three aspects of carbohydrate catabolism, namely, malic acid production in crassulacean acid metabolism, and anaerobic and aerobic respiration. The results of broad physiological studies involving the measurement of gaseous exchange are related to our steadily growing knowledge of partial reactions in these abstracted processes. However, some emphasis is laid on the existence of gaps in our knowledge, especially of stages in the aerobic catabolism of carbohydrates in higher plants, and on the need for continued efforts to verify, by experiment, hypotheses based largely on work with animal tissues, yeast and bacteria.

EDUCATION OF AFRICANS IN EAST AND CENTRAL AFRICA

THE subject of the presidential address to Section L (Education) raises so many issues that Mr. A. L. Binns has had to select for discussion in his address only a few of the many problems which the title indicates. Mr. Binns points out that the history of education in the seven British territories of East and Central Africa seldom goes back more than a quarter of a century, and he is full of admiration for what has been done in such a short time by so few people with such slender resources. These territories depend for the most part on agriculture, which is often very primitive in its methods and implements, and the funds available are very small in comparison with the expenditure to which we are accustomed in Great Britain.

Education is administered by the Colonial Civil Service, working in co-operation with the Christian Churches except in those areas where the people are Mohammedan. A comparatively small number of European teachers is working very hard to train Africans to follow in their footsteps. Owing to difficulties of finance, religion and communications, the training of the African teacher often leaves much to be desired in both content and method, but a great effort is being made to improve matters. The teachers' training centres must be small by British standards, but at present some of them produce less than a dozen teachers annually and lose in both efficiency and economy for that reason. The curriculum followed in the schools has the aim of enabling the Africans to lead the fullest possible life in their own environment, and to improve that environment as quickly as possible; but some Africans would like to copy too closely the aims and methods of European education which are, of course, related to entirely different environment, culture and traditions. Some Africans are also prone to mistake the means for the end and to regard education as designed to enable them to pass examinations rather than to lead a good life. Many people in Great Britain fall into the same error, but it is natural that a people who are emerging from a primitive way of life should be especially open to the temptations of an education academic and examination-ridden. Language is a real difficulty in most of the schools of these territories, for the tribal vernaculars are very numerous, they arise from a number of language roots, and they are often limited to such a small number of users that these languages have little literature and sometimes even no school text-books, simply because the market is too small to make printing economically possible. A lingua franca to be used in addition to the tribal vernaculars is essential to progress, and it must be a lingua franca current over a wide area, with a rich literature and fully equipped for use in technical education and in commerce. Swahili, which has been used to some extent as a lingua franca, fails in some of these respects but has stood in the way of a better common language.

The population of many of these territories is increasing very fast, and increased productivity is essential. There is here a vicious circle, for increased productivity is a condition of the spread of education for financial reasons, while productivity cannot expand rapidly until we have an educated population. So many other things depend on the advance of education in East and Central Africa that the vicious circle thus described must be broken into to raise the moral stature as well as the material resources of these countries, and to enable their inhabitants to lead a fuller life.

BRITAIN'S FOOD SUPPLIES

IN his presidential address to Section M (Agriculture) Dr. N. C. Wright opens with a reference to the leading part which the British Association has always taken in relating nutritional needs to national life, notably by the pioneer survey of food consumption and expenditure made by a special Committee of the Association in 1880. This survey had already shown the increasing dependence on overseas food supplies which accompanied Britain's rapid industrial development in the nineteenth century. During the fifty years between 1880 and the 1930's this trend was continued, until in the immediate pre-war years Britain relied on imports to the extent of some 70 per cent of the total calorie value of the food supplies. This excessive dependence on overseas supplies was inevitably accompanied by the neglect of the food-producing potentialities of British agriculture.

With the outbreak of war in 1939 the country had to face drastically reduced overseas food shipments, which by 1942 had fallen to only half the pre-wa figure. To meet this serious menace to the food supply it was necessary not only to re-plan the impor programme but also to re-develop British agricultura production. From the nutritional aspect there were three main objectives in planning this re-orientation of the country's food supplies: first, to ensure an adequate calorie-level in the national diet; second to furnish sufficient supplies of 'protective' foods particularly for the vulnerable groups of the population; and third, so far as possible to provide a die which was reasonably varied and palatable. The first objective was achieved by expanding substantially the home production of crops which furnished maximum calories for direct human consumption, for example, wheat, potatoes and sugar beet. This inevitably involved substantial reduction in the livestock population, notably in the number of pigs and poultry—though such reductions were partially offset by large increases in the home output of coarse grains. The second objective was achieved partly by increasing the supplies of liquid milk and subsidizing its consumption, partly by expanding the acreages under vitamin-rich vegetables, and partly by adopting processing techniques designed to increase the 'protective' value of certain staple food such as bread and margarine. The third objective was achieved by changing the pattern of imports to include a higher proportion of the more palatable and concentrated foods, and by increasing the home production of certain highly flavoured crops. As a result of these combined measures the nutritiona value of the diet was actually improved during the War.

The immediate effect of the cessation of war was to create greatly increased demands on the world's available food supplies. Simultaneously Britain had to face the loss of Lend-Lease aid. Since anima products represented the most expensive drain on the country's currency, the main objective of the 1947 agricultural expansion programme was to re-expand the livestock population; but to do so not only on the basis of substantially increased dependence on home-produced animal feeds but also without any appreciable reduction in the home contribution to the total calories of the national diet. The extent to which this was achieved is shown by the figures for home production in 1950.

Although both the war and post-war increases in home food production were associated with marked changes in the pattern of land usage, they were also largely due to technical improvements designed to increase both yield and productive efficiency. These improvements included very substantial increases in fertilizer usage, in farm mechanization, in crop protection methods, and in the productivity of crops and stock, as well as of grassland.

An examination of the country's future food requirements indicates that largely owing to the gradual equalization of demand between differen income groups these are likely to increase. At the same time, both the availability of world supplies and Britain's balance of payments problem are likely to limit the country's ability to purchase food from overseas. The need for a further expansion in home production is therefore assured. Whether such expansion will involve a further marked re-orientation in the pattern of land usage cannot be forecast, but there is no doubt that even within the present pattern there is still ample scope for improvement by the wider application of science to farming practice.

LOCAL SCIENTIFIC SOCIETIES

THE title of the presidential address to the Conference of Delegates of Corresponding Societies being delivered by Mr. J. A. S. Stendall is "Problems and Responsibilities". After tracing the history of societies in Northern Ireland and directing attention to men eminent in their own spheres of activity, Mr. Stendall turns to the decline in publications issued by local societies. This, he suggests, is possibly not due to lack of interest on the part of those responsible, but rather to present-day conditions. Fewer reports and proceedings of societies are being published and still fewer records of accomplished work made available, owing to the prohibitive increase in printing costs. This is to be deplored. Mr. Stendall thinks that societies should subsidize regional journals rather than attempt their individual publications and in this way cut their own costs, allow for an increase in size of the journals, bring all regional records together and reduce time-lag in the publication of important papers.

Following a brief account of the natural scene in Northern Ireland, an appeal is made to members of the local societies to give more consideration to the importance of preservation by law of several well-known areas of great interest—scenically, archæologically and naturally. Great Britain has scheduled many such areas, but nothing in this respect has been done in Northern Ireland, notwithstanding favourable recommendations contained in the 1946 Interim Report of an officially sponsored Planning Advisory Board on Amenities.

An appeal is made for the control of ivy growth, especially on trees. Locally many fine trees have been killed by ivy strangulation; to-day there are numbers tending that way, while potential victims are legion, especially those growing along roadsides. Similar conditions appertain farther afield than Northern Ireland.

Turning to local achievements in the preservation of Nature, Mr. Stendall refers to the value of the Wild Birds Protection Act (N.I.) 1931, which swept away outmoded legislation, similar to that which holds in other parts of the United Kingdom to-day, ranging as it does back into the 'eighties. Northern Ireland, fortunate in being a compact area, lends itself to the now admitted justifiable experiment of deeming all species of wild birds to be protected, with the proviso that any undesirable members of the family could be contracted out, while a close season is given to birds of sport. The Act is administered by the Home Office of the Northern Ireland Government, with a special committee to advise the Minister. At the moment, there are seventeen species completely unprotected, two species can only be taken on enclosed land, while sporting birds of winter can have their close season altered and even be given complete protection for a definite period if necessary. All nests and eggs are protected, except those of the blacklisted species. The Minister has the power to transfer species from, and to, complete protection, while police have to be able to recognize but few species. Mr. Stendall suggests that local societies could do much to bring about legislation of a like nature in Great Britain.

OBITUARIES

Sir Jack Drummond, F.R.S.

THE insensate murder, on the night of August 4, of Sir Jack Drummond, together with his wife and their twelve-year-old daughter Elizabeth Anne, will have brought rage and grief to many hearts. Debonair would be the best single word to describe him; he attracted friends as the sparks fly upwards.

He was born in 1891. The history of his scientific work typifies and illustrates the development of biochemistry in Great Britain. Graduating from Queen Mary College and King's College, London, he became a research worker at the Royal Cancer Hospital, London, in 1914, and remained there for five years, when he was appointed reader in physiological chemistry at University College, London. This appointment, in which he succeeded the first reader in the subject to be created in the University, Dr. R. H. Aders Plimmer, was to the staff of the Department of Physiology. The post was made into a professorship in 1922, the Department then being known as the Department of Physiology and Biochemistry, which title it retained until his resignation in 1946 to become director of research to Boots Pure Drug Co., Ltd., after which a separate Department of Biochemistry was created.

The long list of Drummond's published papers emphasizes the unfolding of the subject of biochemistry. He had begun work on nutritional subjects, particularly on the so-called 'accessory substances', while at the Royal Cancer Hospital, and under the influence of Casimir Funk. In 1922 he was publishing the results of a search for the fat-soluble factor, then called vitamin A, and investigating its origin. At that time, although Mellanby had shown the antirachitic properties of the factor, it had not yet been separated into the A and D fractions—this happened about 1924. He passed on to study high protein diets, further properties of the non-saponifiable fraction of cod liver oil, and to the antirachitic properties of irradiated sterols, in 1925. The following year he went back to the question of the chemical nature of vitamin A, discussed its possible relation to carotene, which was rejected because he could not confirm the growth-promoting action of the latter, and he evolved the arsenic trichloride colour reaction. After working for two years on vitamin B in relation to diet and inanition, he returned in 1930–31 to the question of the relation of vitamin A to carotene, and this he now confirmed, explaining the former failures by the fact that the carotene had been given in solution in ethyl oleate, which oxidized easily and led to destruction of the carotene. For the time it appeared that carotene and vitamin A were, in fact, identical; but in 1932 T. Moore, of Cambridge, showed that the vitamin was formed from carotene in the body, and this Drummond confirmed.

Attention was next turned to more practical questions of the nutritive value of bread, the effects of milling, of the seasonal alterations in milk, and of the effects of fat-free diets; he also worked on vitamin E, which had recently been isolated.

It must be mentioned that nearly all this large amount of published work was carried out in collaboration with others, and they were many and often distinguished, or destined to become so; Drummond was, however, the senior partner in most of these publications. I think he exerted much more influence through his inspiration of junior colleagues, and by his example of first-class work than by any actual event of discovery, in which, despite immense efforts, he was, on the whole, not over fortunate. That he played a very large part in the general development of the biochemistry of nutrition nobody can doubt; but it was more by example, by the application of first-class chemistry, by his innate appreciation that mere chemistry is not enough, and by the coordination of wide chemical with biological knowledge rather than by resounding discoveries that he did so.

When the War came in 1939, he was clearly indicated as the most suitable person for the responsible post of scientific adviser to the Ministry of Food, which he held until 1946, in the later years of the period being also adviser on nutrition to the Allied Post-War Requirements Bureau and S.H.A.E.F., and adviser on nutrition to the Control Commissions for Germany and Austria (British Element). He was knighted in 1944, and shortly afterwards was elected a Fellow of the Royal Society. Great Britain owes to Jack Drummond and to the Minister, Lord Woolton, who gave him a pretty free hand, an incalculable debt for the fine work they did in connexion with the British rationing system, which was finely conceived, brilliantly executed, and a pattern to all nations.

Drummond was interested in food from every aspect; he was a very good judge of food and knowledgeable as to its preparation, and he brought, as often as he could, to good food, good fellowship. Very many have spent many a happy hour with him, enjoying good fare, good conversation, and good fun at one of his clubs, at some private dining club, which he always enlivened, or in his own home, where he was the perfect host. We shall all think, often and often, of those very well-spent evenings, and shall not forget.

Lady Drummond (*née* Wilbraham) was his second wife; she was interested in history, and collaborated with him in the production, in 1939, of an entertaining book, "The Englishman's Food" (Jonathan Cape), which abounds in sound scholarship and humour.

'Jack' was full of energy and enterprise, and with a lively sense of humour, which extended to telling stories against himself. He had travelled widely, and with wide-open eyes. Hatred was foreign to his nature, though he freely expressed amused contempt for any kind of pomposity or priggishness; to some, therefore, he might have been unacceptable. Beneath the twinkling eye there was, nevertheless, a steely inflexibility of purpose, and he could be devastating towards incompetence and astringent to fools. Lecturing came easily to Drummond; he was bright, informative and had a gift for popular exposition; accordingly he gave many popular lectures to large audiences, both in Great Britain and in the United States, and these lectures were greatly enjoyed.

His connexions with the industrial aspects of biochemistry, and especially with the food industry, were close, and mutually beneficial. Few realized more clearly than he that our standard of living, together with the sweets of academic life, represent the cream skimmed from industrial endeavour, and he probably supplied more young men for industrial undertakings than any other three biochemists put together; these young men did him great credit and they not infrequently gained distinction in both pure and applied science.

Very many young people owe to Sir Jack Drummond their start in life; he liked young people, and put on no professorial airs for their benefit. If any memorial to him is to be created, he would have liked nothing better than something which would enable capable young people to receive an encouraging start, such as he gave to so many. It would also keep alive the name, for those whose loss it was not to have known him, of a great and lovable personality.

C. Lovatt Evans

The late Sir Jack Drummond was a man of outstanding ability. He was a scientist with an international reputation as one of the leaders in developing what has been called the newer knowledge of nutrition. By applying the scientific method of approach to the administrative problems in the Ministry of Food he made a great contribution to the success during the Second World War of food policy, the outstanding feature of which was the special provision for the nutritional needs of mothers and children. The resulting big improvement in the health and physique in the rising generation in a time of acute food shortage was a remarkable achievement. As one of those who got this policy adopted, and for his work in helping to get it carried through, he rendered great service to Great Britain.

Boyd-Orr

Mr. J. R. Park

British applied science has suffered a severe loss in the untimely death of Mr. J. R. Park, a managing director of the British Oxygen Co., Ltd. Mr. Park was born in London in 1902 and was educated first at Battersea Grammar School and then at Queen Mary College, where he graduated in chemistry. After a short period on the staff of Westminster Technical College he worked as an analytical chemist in industry for a number of years in Britain, followed by a year in a French firm.

In 1929 Mr. Park joined Imperial Chemical Industries, Ltd., Billingham Division, where he remained until 1945. For a time he worked there as a plant manager, but soon he switched over to the research side. The production of hydrogen, the hydrogenation of coal, the ammonia synthesis and methanol synthesis were some of the fields which occupied him in the years up to the Second World War, when he had advanced to the position of ammonia research manager. He was also connected with the design of oil hydrogenation plant, and in the first year of the War was responsible for the design of various other plants.

I made his acquaintance in 1941, when Park was put in charge of the I.C.I. Billingham research team working on the British Atomic Energy Project. His quick grasp of problems, his strong scientific background and his understanding of large-scale industrial processes formed a combination that contributed greatly to the success of the enterprise.

In 1945 Park was asked to organize a research department in the British Oxygen Co. He did this with outstanding success, creating within a few years a large and flourishing research organization practically from scratch. His worth was quickly appreciated;

in 1948 he became assistant managing director, and soon was promoted to the post of managing director. It is largely due to Park that the British Oxygen Co. has been transformed from an undertaking relying mainly on foreign patents into a modern enterprise standing on its own feet in the field of research and development. Park was one of the all too small group of first-class chemical technologists who are essential for the economic future of Great Britain; his death leaves a gap which will be felt for a long time. His friends mourn the passing of a personality of wide interests and great charm, and of a warm-hearted and loyal companion.

F. E. SIMON

We regret to announce the following deaths:

Sir Frederic Kenyon, G.B.E., K.C.B., during 1909–30 director and principal librarian of the British Museum, on August 23, aged eighty-nine.

Dr. Albert Mansbridge, C.H., founder and first secretary of the Workers' Educational Association, on August 22, aged seventy-six.

NEWS and VIEWS

The Nature Conservancy:

Captain C. Diver, C.B., C.B.E.

Captain C. Diver is retiring on December 1 from the post of director-general of the Nature Conservancy. He was appointed to his present post four years ago to implement the Government's decision to establish the Nature Conservancy. After being invalided out of the Army, in 1919 he was appointed to a clerkship in the House of Commons and remained in the service of the House for the next twenty-nine years, relinquishing his appointment as principal clerk of committees to take up his present post. Throughout the Second World War he was clerk to the Select Committee on National Expenditure. In the field of biology Capt. Diver has worked as an amateur. Very early he developed an interest in land and freshwater Mollusca and a little later in the mosses. After the First World War, he received much help and encouragement from Bateson, and collaborated with Boycott and others in experiments on the genetics of inverse symmetry in *Limnaea*. He also studied the distribution of genes in natural populations of *Cepaea*, and the behaviour and web-building of the garden spider. In 1930 he began the ecological survey of South Haven Peninsula, Studland, on the Dorset coast, and soon enlisted the help of Prof. R. D'O. Good and many others. This work, for which he received a Leverhulme grant, continued steadily for the next nine years until brought to an abrupt close by the declaration of war. He was a member of the Nature Reserves Investigation Committee set up in 1942 under the auspices of the Society for the Promotion of Nature Reserves, and he was largely responsible for the contents of its report. This report furnished the basic data for the work of the Wild Life Conservation Special Committee which was appointed in 1945 by the Ministry of Town and Country Planning to work in conjunction with the Hobhouse Committee on National Parks. He took a leading part in the work of the Special Committee, the report of which ("Conservation of Nature in England and Wales". Cmd. 7122. 1947) he drafted at the unanimous request of the Committee. It was largely informed by his ideas and policies, and the acceptance by the Government of its main conclusions brought the Nature Conservancy into being.

Mr. E. M. Nicholson, C.B.

Mr. E. M. Nicholson, who has been appointed by the Nature Conservancy, with the approval of the Lord President of the Council, to succeed Captain Diver as director-general, is a charter member of that body. He brought to the service of the Conservancy a valuable combination of administrative experience and expert ornithological knowledge; and he assumes his new duties as one who not only was a member of the Wild Life Conservation Special Committee but has also taken an active part in the work of the Conservancy since its inception. During the War, he served in the Ministry of Shipping, later the Ministry of War Transport, where as head of the division in charge of Middle East supplies he was responsible for sending out the Kerr-Worthington scientific mission. From 1945 until May of this year he was secretary of the Office of the Lord President of the Council, and is a member of the Advisory Council on Scientific Policy. For the past few months he has been in Baluchistan as the leader of a United Nations Economic Development Survey team. Birds and ornithological affairs have been Mr. Nicholson's life-long interest, and he has published scientific papers and several books on this subject; in 1927 he organized and directed the Oxford Bird Census, in which university ornithologists, botanists and entomologists collaborated in field surveys; and in the two following years he organized the Oxford University expeditions to Greenland and to British Guiana. He has been secretary, vice-chairman and chairman of the British Trust for Ornithology and has taken a leading part in other ornithological activities.

Natural History at Edinburgh:

Prof. J. Ritchie, C.B.E.

With the retirement of Prof. James Ritchie from the chair of natural history at the end of the current session, the University of Edinburgh will lose the services of a distinguished naturalist and inspiring teacher. In his student days he came under the influence of Sir J. Arthur Thomson at Aberdeen and proved a worthy successor to that line of all-round scientific naturalists of which Scotland is justly proud—a type all too rare in these days of specialization. A brilliant record as a student saw the award of an M.A., a B.Sc. and in 1912 a D.Sc. In 1907 he entered the Royal Scottish Museum as an assistant and in 1921 became keeper of the Natural History Department. In 1930 he was appointed regius professor of natural history in Aberdeen and transferred to the chair at Edinburgh in 1936. Among the other posts he has filled are: five periods on the council, one as secretary and two as vice-president of the Royal Society of Edinburgh, president of Section D (Zoology) of the British Association, editor of the *Scottish Naturalist*, vice-president of the Zoological Society of Scotland and membership of various bodies concerned with the conservation of wild life.

His zoological researches commenced with a series of papers on Hydrozoa but soon extended to other marine invertebrates, land and water vertebrates and archæology. One of his interesting economic suggestions, a method of keeping the submarine shafts of an electricity station free from blocking by the invasion of mussels, has been in successful operation since 1927. It is not possible in a brief note to do justice to his remarkable energy and enthusiasm nor to the wide range of his knowledge and interests. His services were recognized by the conferment of a C.B.E. in 1948 and an honorary LL.D. by Aberdeen this year. His skill in drawing is reflected in all his work, and outside scientific circles has been recognized by the Royal Scottish Academy, which has exhibited a number of his delightful water colours. A most approachable man, he has always been ready to share his knowledge and to encourage the humblest of inquirers. Many have enjoyed his loyal friendship and some perhaps a round of golf with him.

Dr. M. M. Swann

Dr. Michael Meredith Swann has been appointed to succeed Prof. Ritchie. Educated at Winchester and Cambridge, Swann, after graduating in 1940 with a first-class in zoology, joined the Intelligence Corps, served in Iceland as a captain instructor in arctic warfare, benefiting by his earlier experience with the Cambridge Iceland Expedition of 1939, and was thereafter engaged in operational research in Great Britain and Normandy. When, as lieut.-colonel in the Scientific Adviser's Branch of the War Office, he was demobilized in 1946, he returned to the Zoology Department at Cambridge as temporary demonstrator, with a research fellowship at Gonville and Caius College. He has been a University demonstrator since 1948. Dr. Swann has devoted himself actively to the investigation of the cell, and his studies have followed three main lines—the refinements of mitosis, the fertilization reactions of sea-urchin eggs, and the mechanical properties of cell-membranes. In the first, his Ph.D. thesis (1950) was on "Structural Factors in Mitosis", and with J. M. Mitchison he has elaborated the use of polarized light in the study of cell changes affecting membranes, mitosis and cleavage. In the second, in collaboration with Lord Rothschild, he has elucidated the responses of the sea-urchin egg to contact with spermatozoa, and in the last he, along with Mitchison, has attempted to link the processes of cell-cleavage with the physical properties of the cell-membrane. At the age of thirty-two years Dr. Swann is not the most youthful of Edinburgh's long succession of professors of natural history, but to better his record one must go back to 1804 and the appointment at the age of thirty of Robert Jameson, the teacher of Charles Darwin, Edward Forbes, Sir William Jardine, William Scoresby, John Goodsir and many other well-known naturalists.

Research at Edinburgh on Cancer

From the estate of the late George Fisher Melville, advocate, of Edinburgh, the sum of £270,000 has now become available for the encouragement of activities relating to "the care and cure of cancer". Some time ago, Messrs. Tod, Murray and Jamieson, W. S., of Edinburgh, in whose hands the affairs of the estate rest, sought the advice of representatives of the Royal Colleges of Medicine and of Surgery of Edinburgh and of the University, and with the help of this *ad hoc* committee so formed drew up a scheme for the appropriate utilization of this money. This scheme has now gained the approval of the Court of Session. The next step will be the formal approach by the trustees to the Royal Colleges and to the University of Edinburgh requesting that each of these bodies shall nominate a trustee and three members of a permanent scientific advisory committee which will at once proceed to formulate recommendations for carrying the scheme into practical effect. Since the care of the patient is now a responsibility of the State, it is certain that the scientific advisory committee will be mainly, if not exclusively, concerned with the encouragement of research into the nature and causes of malignancy, and thus into the ways in which it may be prevented, treated and controlled. The hands of the trustees are not tied. They are empowered to nourish researches being undertaken in hospitals and elsewhere, to build and equip new laboratories, to institute research fellowships and to amalgamate or to form alliances with other bodies actively interested in the same general field of inquiry. In these days, opportunity of this magnitude knocks but very rarely upon the doors of Scottish academic institutions. The responsibility to be assumed by the scientific advisory committee is, therefore, exceedingly heavy. To exploit this opportunity to the best advantage to all concerned—to those who suffer and to those who seek knowledge that may give power to abolish suffering—will demand the exercise of much wisdom. Of this there is in Edinburgh a rich store.

Popular Interests in Science

An investigation into the interests of about 391 people (241 males, 150 females) who are taking science subjects in adult education classes showed that the females were more extreme in their preferences and dislikes than the males (*Health Educ. J.*, 9, No. 4). Males were most interested in studying future advances and new discoveries and theories in science and, next to these, medicine, health and the industrial applications of science. Medicine and health were the most popular subjects for females, and almost as popular were pure biology and psychology. Neither males nor females took much interest in aeronautics or in the public direction and use of science; even less interest was shown in the work of scientific institutions and the results of science surveys and commissions. This may indicate that the 'ordinary' man is not fully conscious of the impacts of science on communal life or, perhaps, is little interested in the development of society as distinct from the individual. Confirmation of this investigation was obtained from a group of men in an Army education college. Although the men were not necessarily interested in science, their likes and dislikes were very similar to those of the younger men in the original group.

C. T. R. Wilson and the Cloud Chamber

The fourth in the series of attractively illustrated monographs dealing with the association of prominent men of science with the Cambridge Instrument Co., Ltd., is entitled "C. T. R. Wilson and the Cloud Chamber" (pp. iv+16; from 13 Grosvenor Place, London, S.W.1; 1952; free) and is written by S. Barron, with a foreword by Sir Lawrence Bragg. Reference is made, both in the foreword and in the text, to Wilson's skill and patience in building apparatus and to the remarkable success of the first complete cloud chamber constructed by Wilson in the Cavendish Laboratory, Cambridge, in 1911. This instrument was the only one used by Wilson for his many subsequent researches and is preserved now in the Cavendish Museum where it is still, after forty years, as capable of producing perfect ray-tracks as when it was first demonstrated. In 1913, the Cambridge Instrument Co. obtained permission to make a cloud chamber similar to Wilson's original model, and the Company's first instrument, together with subsequent developments, such as the Wilson–Shimidzu raytrack apparatus (1921), the student's demonstration cloud chamber (1927) and the reciprocating cloud chamber built for the 1951 Festival of Britain, are all fully described and illustrated in the monograph.

Standards of Light at the National Physical Laboratory

"LIGHT" is the second in the series of pamphlets on units and standards of measurement employed at the National Physical Laboratory, Teddington (pp. 8. London: H.M.S.O., 1952; 6d.). The first dealt with the fundamental units of length, mass and time, and the third will deal with electrical units. In the pamphlet on light, the units and systems of measurement used in the Photometry, Colorimetry and Radiometry Sections of the Light Division of the Laboratory are defined. The units are those normally employed in reports and certificates issued by the Laboratory. Brief particulars describing the derivation of the units are provided, and reference is made to those which are accepted internationally. The topics discussed in the photometry section of the pamphlet are the candela, the unit of luminous intensity; the lumen, the unit of luminous flux, the distinction between the units of illumination on the British and metric systems; the stilb and the nit; the scotopic system of photometry; and colour temperature. The requirements of the standard trichromatic system of colorimetry adopted by the Commission Internationale de l'Eclairage are set out clearly in the colorimetry section, and, under the third heading of the pamphlet, "Radiometry", the instruments, particularly the Callendar radiation balance and its more recent successor the Guild drift radiometer, for the measurement of the rate of transference of energy by electromagnetic radiation, are briefly discussed. Industrial and research laboratories will find this series of pamphlets most helpful in interpreting test certificates and in ensuring that results of measurements are expressed in agreed and internationally recognized units.

Principles of Extraction and Refining of Metals

THE Institution of Metallurgists has published the five lectures on the "Principles of the Extraction and Refining of Metals" given under the presidency of Mr. E. W. Colbeck at its refresher course in 1950. Starting off with an introductory lecture on the use of physical chemistry in extraction operations, which is concerned mainly with thermodynamic principles, the place of mineral dressing in extraction metallurgy is then considered; this is, in the main, economic and technical. A lecture of unusual interest on the principles of ore reduction, by Prof. C. W. Dannatt, goes far towards systematizing the large number of procedures which are used for obtaining crude metal from its ore. The fundamentals of the production of ingots are then discussed, and the course is concluded by a lecture on the principles underlying refining processes, using the fundamental chemical principles previously outlined. All who are concerned with the extraction and refining of metals will find in this short monograph a large amount of material of direct interest, much of it by no means easy to find, nor so well digested, elsewhere. As is said in the concluding paragraph of the last lecture: "The refiner will find it vastly to his advantage to employ thermodynamics in order to recognize both the results which may theoretically be achieved in the ideal process, and those which are inherently impossible under his conditions of working".

King George III Collection of Scientific Instruments

A DESCRIPTIVE catalogue of the King George III collection of scientific instruments, issued by the Science Museum, London (pp. 92+8 plates; London: H.M.S.O., 1951; 7s. 6d. net), is of interest in throwing light on the activities of individual instrument-makers practising during the latter half of the eighteenth century. The catalogue is divided into sections according to the various branches of science recognized at the present time, for it should be realized that in the days of George III scientific specialization was not known, since the philosophers—as they were called—did not confine their studies to one branch of knowledge. The sections of the catalogue include mechanics, heat, pneumatics and hydrostatics, chemistry, astronomy and time measurement, optics, surveying and mathematical instruments, acoustics, magnetism, electricity, manuscripts and miscellaneous. The catalogue is illustrated and concludes with notes on the location of the other portions of the original collection and a list of makers of the instruments.

Colonial Plant and Animal Products

IN the latest issue of the quarterly journal of the Colonial Products Advisory Bureau (Plant and Animal) (2, No. 3), R. H. Kirby continues his series of articles on seaweeds in commerce. Besides accounts of the use of agar-agar in the British Commonwealth and other countries, Kirby also describes the manufacture of algin in the United States and other parts of the world. Other articles include one on aromatic grasses of commercial importance by E. Brown and W. S. A. Matthews, and the market for mangoes and mango products by E. H. G. Smith. Reports of recent investigations at the Colonial Products Advisory Bureau include that on the use of trigona wax from Tanganyika, manila hemp from Malaya, pewar or peach nuts from Trinidad, a description of drying trials with goat skins in the Sudan and the possibilities of using cocoa husks from the Gold Coast as a source of furfural.

Annals and Magazine of Natural History

FOR a century and a quarter the *Annals and Magazine of Natural History* has held an honoured place among biological journals; all-embracing in its earlier years, it has of late tended to include particularly systematic and morphological papers in zoology, palæobotany and palæontology. The proprietors of the journal, Messrs. Taylor and Francis, Ltd., with the support of the editorial board, have now decided to widen its scope by combining with it the *Journal of Botany*, which had to cease publication during the Second World War. The editorial board, Sir Guy Marshall, Dr. W. T. Calman, Prof. H. L. Hawkins and Mr. W. N. Edwards, will thus have the assistance of Dr. George Taylor, keeper of botany in the British Museum (Natural History), and in view of the importance of the entomological papers in the *Annals*, Mr. E. B. Britten, of the Department of Entomology at the British Museum, is also to join the board. Biologists will welcome the extension of the field of this old-established journal and wish it a new lease of life.

Forty Years of X-Ray Diffraction: Anniversary Meeting in London

The X-Ray Analysis Group of the Institute of Physics is holding a meeting at the Royal Institution, Albemarle Street, London, W.1, during October 24–25, in celebration of the fortieth anniversary of the discovery of X-ray diffraction by Friedrich, Knipping and von Laue (see *Nature*, June 7, p. 949). After an opening historical address by Sir Lawrence Bragg, four papers will be read: "The Growth and Scope of X-Ray Crystal Analysis", by Prof. J. D. Bernal; "Chemical Problems", by Dr. D. Hodgkin; "X-Ray Analysis and the Metallic State", by Prof. G. V. Raynor; and "The Application of X-Ray Analysis to Protein Structure", by Sir Lawrence Bragg. A commemorative dinner will be held on October 24, in the Criterion Restaurant, Piccadilly Circus, at which the guests of honour will be Prof. M. von Laue and Prof. J. M. Bijvoet. During the two days of the meeting there will be an exhibition in the Royal Institution of historical X-ray apparatus, etc. The meeting is open to all. Application forms for attendance (to be returned by September 20) and further information can be obtained from the Deputy Secretary of the Institute of Physics, 47 Belgrave Square, London, S.W.1.

Royal Photographic Society: Annual Exhibition

The ninety-seventh annual exhibition of the Royal Photographic Society will be opened by the American Ambassador, Mr. W. S. Gifford, on September 11, in the Society's House, 16 Princes Gate, London, S.W.7. It will be open to the public without charge from September 12 until October 12, inclusive, from 10 a.m. to 8 p.m. each day (Saturdays, 10 a.m.–5.30 p.m.; Sundays, 2.30–5.30 p.m.). After the London display, the whole of the exhibition will be transferred to Leeds for the period October 25–November 23, and to Bristol for the period December 6–31.

Foot-and-mouth Disease Inquiry

The Minister of Agriculture and Fisheries has appointed a committee to review the policy and arrangements for dealing with foot-and-mouth disease in Great Britain, and to advise whether any changes should be made in the light of present scientific knowledge and the technical and administrative experience gained in recent years in this and other countries. The Committee is constituted as follows: Sir Ernest Gowers (chairman), Prof. E. D. Adrian, Colonel H. Cator, Dr. Ll. Wyn Griffith, Lord Hungarton, Prof. A. Robertson, A. R. Semple, and H. Woolley. R. A. Thorne, of the Ministry of Agriculture and Fisheries, has been appointed secretary to the Committee. Communications should be addressed to him at Hook Rise, Tolworth, Surbiton, Surrey.

Rajasthan Academy of Sciences: Officers

At the second annual meeting of the Rajasthan Academy of Sciences, Pilani, the following officers were elected: *President*, Dr. G. S. Mahajani, vice-chancellor, University of Rajputana; *Vice-Presidents*, Dr. N. N. Godbole, director of industries and commerce, Rajasthan Government, and Dr. A. Mookerji, professor of physics, Birla College of Sciences; *Secretary*, K. Ramamurti, Birla College of Science, Pilani. Mr. M. L. Schroff and Dr. M. L. Roonwal, as ex-presidents of the Academy, serve as vice-presidents, and Mr. Roshan Singh continues to be the treasurer.

Announcements

A discussion on "The Place of the Scientist in Civil Defence" has been arranged by the Royal Institute of Chemistry (London and South-Eastern Counties Section) with the Institute of Biology and the Institute of Physics (London and Home Counties Branch) and will be held on October 16 at 6.30 p.m. in the City of London School, Victoria Embankment, London, E.C.4. The principal speakers will be: Sir John Hodsall, Sir Charles Ellis, Dr. E. T. Paris, Prof. W. V. Mayneord and Prof. H. N. Rydon.

A seminar on polymer science is to be held in the Department of Chemistry, University College, London, W.C.1, during the autumn term. Eight lectures, by different speakers, will be given on Fridays at 4.30 p.m., beginning October 17. Visitors will be welcome.

A conference on the "Growth of Protozoa" will be held during October 24–25 at the New York Academy of Sciences under the joint sponsorship of the Academy and the Society of Protozoologists. The first day will be devoted to free-living forms, and the second to parasites. The programme is designed to be of broad biochemical, morphological and medical interest. The proceedings will be published in the *Annals* of the Academy. Further information can be obtained from the secretary of the Society, Prof. E. R. Becker, Department of Zoology and Entomology, Iowa State College, Ames, Iowa.

The Sixth Congress of the International Scientific Film Association will be held in the Maison de la Chimie, 28 rue St. Dominique, Paris 7^e, during September 23–October 1. During the Congress there will be meetings of the General Assembly of the International Scientific Film Association, meetings of the permanent committees dealing respectively with medical, research, technical and industrial films, and a festival of scientific films. At the Congress Great Britain will be represented by the British Scientific Film Association, and further information can be obtained from the administrative officer of the Association at 164 Shaftesbury Avenue, London, W.C.2.

The Council of the City and Guilds of London Institute has conferred the fellowship of the Institute on the following past students of the City and Guilds College: L. H. Bedford, chief television engineer, Marconi's Wireless Telegraph Co., Ltd.; H. F. Cronin, chief engineer, Metropolitan Water Board; W. A. Del Mar, chief engineer, Habirshaw Cable and Wire Division, Phelps Dodge Copper Products Corp., United States; H. J. B. Harding, director, John Mowlem and Co., Ltd., and also of Soil Mechanics, Ltd.; W. H. G. Roach, managing director, William Press and Son, Ltd., technical director, D. and C. and William Press, Ltd., director of the General Descaling Co., Ltd., and also of John Paul and Co., Ltd., Dublin.

ELECTRONIC INSTRUMENTS AND EQUIPMENT

EXHIBITION IN MANCHESTER

THE seventh annual exhibition of the North-Western Branch of the Institution of Electronics, which was held in the College of Technology, Manhester, during July 15-18, had a record number of xhibitors, more than forty concerns—universities and esearch associations as well as private firms—being epresented. There were, in addition to the trade xhibits, demonstrations of equipment in the research tage and a number of special displays dealing with igh-fidelity sound recording and with television. Films on electronic subjects, both elementary and dvanced, were shown, and the lecture programme—overing sixteen different topics in all—included talks n technical subjects associated with the special isplays as well as discussions of production methods nd problems by the staff of some of the exhibiting rms.

In his address at the opening ceremony, Mr. A. J. Philpot, director of research, British Scientific nstruments Research Association, remarked that the development of electronics has been much more losely tied to commercial application than that of most sciences, and the academic treatment has tended o follow rather than precede. This trend has cerainly been reflected in these exhibitions, The first five included a succession of striking new applications; but the tendency last year and again this year was owards consolidation—greater reliability, improved fficiency and all the other improvements which go with a better appreciation of the theoretical background. In fact, it would almost be true to say that not one exhibit represented a really new application. This fact probably accounts for the disappointment xpressed by some of the lay visitors; a certain familiarity with the field was necessary for the appreciation of some of the improvements offered. None the less there were improvements, some of them quite striking; but as the scale of the exhibition ncreases it becomes more and more difficult to present an adequate account, and it is more than ever necessary to point out that the items mentioned n this report are simply those which had the strongest personal appeal to the writer.

The Research Laboratory of Associated Electrical Industries, Ltd., demonstrated equipment for measuring infra-red radiation of very low intensity. Normally the minimum measurable intensity is determined by the level of the random noise arising from the lead sulphide detector-cell. In this equipment the incoming signal is chopped by a rotating sector disk and the signal amplified in a narrow-band amplifier. The narrow band is obtained by using the homodyne principle; that is, the incoming signal is mixed with a local signal of the same frequency to produce a beat frequency of zero (namely, a D.C. output). In this way the signal-to-noise ratio is very much increased. The same principle is also being used in the apparatus developed by the Physics Department of the University of Manchester for the detection of very weak light sources (for example, faint stars), which was also on show. In this case the detector is an electron-multiplier cell, cooled in liquid air to reduce the noise-level as much as possible. The best sensitivity so far claimed would allow the detection of 10^{-14} lumens (about 50 quanta of green light per second).

The Department of Electron Physics of the University of Birmingham included in its exhibit an apparatus for producing pulsed magnetic fields of high intensity. Fields of the order of half a million gauss in a volume of a few cubic millimetres can be produced by discharging the energy stored in a condenser through a specially constructed solenoid. In the demonstration a brass washer was hurled several feet into the air by the mutual action of the pulsed field and the field due to eddy currents in the washer. Another application of the sudden discharge of the energy of a charged condenser was included in the apparatus for *Schlieren* spark photography designed by the Fluid Motion Laboratory of the University of Manchester. The condenser is discharged through a simple triggered spark-gap in a circuit of very low inductance to produce a high-intensity flash of very short duration.

In the trade section, the products displayed had a standard of appearance and finish which was very high indeed, and the stands were attractively arranged.

Cinema-Television, Ltd., showed the projector unit and control console of a standard cinema equipment for obtaining a 16 ft. × 20 ft. television picture. The picture from an 8-in. cathode-ray tube is projected by means of a Schmidt optical system. The anode voltage for the tube is 50 kV. and the beam current may rise to 15 mA. A powerful air blast is necessary to prevent over-heating of the screen.

De Havilland Propellers, Ltd., displayed some of their equipment for vibration studies. This included moving-coil vibrators, pick-ups, strain gauges and all the ancillary control and recording gear. The vibrators are like giant moving-coil loudspeaker units with the coil suspended at both ends by a synthetic resin 'spider'. The largest shown was capable of exerting a force of ± 165 lb.-wt.

The familiar, octopus-like mercury-vapour rectifier with six projecting anode tubes can now be replaced by six neat single-anode tubes. These excitrons, displayed by the Rectifier Sub-Station Department of the English Electric Co., Ltd., are air-cooled glass tubes which are provided with control grids. These permit the variation of the output voltage or can be used for arc suppression in conjunction with protective circuits.

The outstanding item on the stand of Ferranti, Ltd., was the transient oscillograph tube. This magnetically focused tube has been specially developed for use in the surge testing of large power-transformers. The fluorescent spot has a high actinic value and, with an $f/1$ lens and normal photographic techniques, clear, full-size negatives of single traces at writing speeds of 30,000 km./sec. can be obtained.

Fielden (Electronics), Ltd., demonstrated a new, servo-operated, self-balancing temperature recorder. The instrument plots the temperature readings for four separate platinum-resistance thermometers in four different coloured inks on the same polar chart. The readings are made in turn at intervals of about five seconds, and a simple but ingenious mechanism rotates the four-point pen to the appropriate position before each reading is recorded.

At intervals throughout the exhibition, recitals were given on the Gregorian electronic organ, which is manufactured by Alfred E. Davies and Sons, Ltd., and the Acoustical Manufacturing Co., Ltd. This organ was designed to imitate as closely as possible the tone of a good pipe organ. The basic tone generators are valve oscillators. Special attention has been paid to the 'attack' problem, and variable delays can be introduced to simulate the speaking characteristics of various pipes. One of the most attractive features from the organist's point of view is that the tone colour of any particular stop is governed by a plug-in unit. This means that changes in specification or in the precise quality of any particular stop can be made quite simply even after installation is complete.

Among the measuring equipment displayed by Marconi Instruments, Ltd., the moisture meter was of particular interest. The basic circuit is an ingenious modification of the Wheatstone bridge, which makes the instrument independent of valve characteristics and voltage variations. It is designed to give reliable results without laboratory conditions and without demanding special skill on the part of the operator. Interchangeable scales and calibrations are available for a long and fascinating list of materials, ranging from alginic acid through groundnuts to vermicelli (plain and egg). Another interesting item was a universal bridge for measuring resistance, inductance and capacitance which is really direct reading; the figures on the dial change when the range is changed, and the precise units in which the quantity is being measured also appear on the dial.

Twentieth Century Electronics, Ltd., exhibited precision cathode-ray tubes in which the screen face was ground and polished inside and outside. Also on this stand were a bewildering variety of Geiger counter tubes. Interesting members of the series were a sterilizable tube for medical applications and a tube with a mica window so thin that, when delivered by air transport, it has to be sealed in a metal can to prevent explosion arising from the lowering of atmospheric pressure.

The exhibition was obviously the result of much hard work both by the organizing committee and by the exhibitors; but the very large number of visitors must have been a very satisfying reward for those concerned. C. A. TAYLOR

DAMPIER: PIRATE AND NATURALIST

By DR. L. HARRISON MATTHEWS

Director, Zoological Society of London

WILLIAM DAMPIER, the pirate whose tercentenary fell on June 8, is famed as a buccaneer, navigator, diarist and traveller; but his prowess as a naturalist is less well known. His careful descriptions of his travels around the world between 1673 and 1700, which enjoyed considerable popularity in their day and had run into a seventh edition by 1729, contain many accounts of the wild animals that he came across.

In the day-to-day accounts of his voyages there are frequent notes about the birds, fishes, insects and other animals that he saw, often with interesting opinions on their gastronomic value. But it is in his descriptions of the countries he visited and their inhabitants and products that he really excels and provides us with some excellent chapters on natural history.

He made many trips to the Bay of Campeachy, cutting logwood and buccaneering, that is, making boucan, a sort of biltong prepared by sun-drying the flesh of wild cattle, and his account of his journey in 1676 gives many pages to the fauna of the region. The first animal he mentions is the "squash", which appears to be the coati-mondi. It is bigger than a cat, and its head is much like a fox's with short ears and a long nose. "The flesh of it is good, sweet, wholesome Meat. We commonly skin and roast it; and then we call it Pig; and I think it eats as well." He gives a splendid account of the spider monkey, "the ugliest I ever saw. They are much bigger than a Hare and have great Tails about two and a half foot long". When he met a company of them in the woods they defied him by bombarding him with sticks and more offensive ammunition, "chattering and making a terrible Noise; and a great many grim Faces, and shewing Antick Gestures". He gives details of the prehensile tails of these monkeys, and tells how one old male came on to a small branch just over his head and "leaping directly at me made me start back; but the Monkey caught hold of the Bough with the tip of his Tail; and there continued swinging to and fro, and making Mouths at me".

The great ant-eater has a tongue "like an Earthworm about five or six inches long" with which it licks up ants, and then "puts it out again to trapan more. They smell very strong of Ants, and taste much stronger; for I have eaten of them". The sloth, "a sad coloured Animal", feeds on the leaves of trees, and takes eight or nine minutes to move one of its limbs three inches; "neither will stripes make them mend their pace . . . they seem insensible, and can neither be frightened, or provoked to move faster".

So his descriptions go on, through the mammals, birds, reptiles and fishes, with some interesting bit of acute observation about each, from the large snakes that are "a lazy sort of Creatures" that "lirk in Trees" to the alligator that bit the knee of Daniel the Irishman and left the marks of its teeth in the butt of his gun; poor Daniel "went limping ever after".

Even in those far-off days of the late seventeenth century, Dampier protested against the reckless slaughter of animals for commercial purposes. He was particularly concerned for the introduced cattle that had run wild in the West Indies, and were so important to the buccaneers. "The Spaniards pick and chuse only the Bulls and Old Cows, and leave the young Cattle to breed; by which means they always preserve their stock entire". But the English and French "kill without distinction; yea, the young rather than the old; without regard to keeping up their stock". The seals of the West Indies were similarly exterminated; there may be a few West Indian seals alive to-day, but they are among the rarest of mammals. Dampier relates how a sealing crew was wrecked on the Alcrane Islands "distant from the coast of Jucatan about 25 Leagues; the biggest is not above a Mile or two in Circuit". By great good fortune the sealers were able to fill their casks with seal oil, and refloat their ship at the expense of two New England ketches that ran on the reef, misled by the lights of their fires.

The smaller and more inconspicuous animals did not escape Dampier's notice, for he tells of the two sorts of land crab, the white and the black, "black Crabs are commonly fat and full of Eggs; they are also accounted the better Meat, though both sorts are very good". He also knew *Limulus*, the primitive horse-shoe crab. Near Campeachy "in the Surf of the Sea, close by the shore, you find abundance of Shell-fish, called by the English, Horse Hoofs, because the under part or Belly of the Fish is flat, and somewhat resembling that Figure in shape and Magnitude; but the Back is round like a Turtles; the Shell is thin and brittle, like a Lobsters; with many small Claws: and by report they are very good Meat; but I have never tasted of them myself. . . . Here are also a sort of Spiders of a prodigious size . . . they have two Teeth, or rather Horns an Inch and a half, or two Inches long . . . black as Jet, smooth as Glass, and their small end sharp as a Thorn. These Teeth we often preserve. Some wear them in their Tobacco pouches to prick their Pipes. Others preserve them for Tooth-Pickers".

In the account of his voyage to Australia or "New Holland" in the *Roebuck* in 1699, Dampier gives even fuller details of the natural history, the birds, beasts, and especially the fishes, and also of the plants that he found. He illustrates many of these in copper plates that, considering the times, are remarkably good. Many of the species are quite easily identified from his sketches, and it could well be claimed that he was one of the first traveller-naturalists.

As is only natural, Dampier gives the colours of the birds and other creatures that he saw, and his descriptions are correct; yet one may doubt whether his colour perception was complete. When he was at Tonquin he saw the galleys of the king's navy which were commanded by a general who "was a great Mandarin. . . . There were two more great Officers under him, each in a Vessel by himself. These three had Flags of distinction: the first was yellow, the second blue, the third red or green". Can it be that Dampier was colour-blind, and could not distinguish red from green?

BRITISH MYCOLOGICAL SOCIETY

PLANT PATHOLOGY FIELD DAY

THE twenty-sixth annual plant pathology field day of the British Mycological Society was held on July 4 in the Mycology Section of the Hawthorndale Laboratories, Bracknell, Berkshire, of Imperial Chemical Industries, Ltd. Sixty-six members attended.

Mr. R. V. Tipler, senior mycologist, reviewing the functions of the laboratories, stated that the main task was the evaluation of chemicals produced in the research departments of I.C.I. manufacturing divisions for possible use in controlling crop diseases, pests and wastage caused by bacteria, fungi, insects and eelworms in agriculture, horticulture and industry. The Mycology Section was concerned with prevention or control of plant diseases and crop wastage and with industrial microbiological problems. The demonstrations were arranged to illustrate the scope of the Section's activities in the field of bioassay. They showed the sequence of testing from first-stage sorting by *in vitro* methods for general antifungal and antibacterial activity to second-stage sorting by *in vivo* methods in laboratory, glasshouse and field to discover applications for promising chemicals in industry and as seed, soil and foliage fungicides. Consolidation work, not capable of being shown at the Laboratories, followed under practical conditions at home and overseas with selected materials, under control of the research staff.

Miss M. E. Kennedy demonstrated methods of maintaining the culture collection. In order to reduce subculturing and minimize possible variations in reactions of test fungi to chemicals or pathogenicity to plants the mineral oil and freeze-drying methods of preservation were used. The former was more suitable for mycelial and non-sporing forms and consisted of culture on agar slopes covered to a depth of 1 cm. above the medium with a sterilized mineral oil. In the latter, suspensions of fungal spores or bacteria, with a protective colloid, were dried *in vacuo* from the frozen state. Standard reference cultures had been preserved unchanged in the characteristics under study for more than four years. The Hawthorndale method of inducing profuse sporulation of *Alternaria solani* was demonstrated. Controlled ultra-violet irradiation of mycelial cultures on agar reliably produced spores within eighteen hours. The method had been in regular use for three and a half years.

Mr. J. L. Charlton showed agar plate and spore germination techniques for *in vitro* screening of chemicals. The first method, based on serial dilution of chemicals in an agar medium which was then inoculated with a range of fungi or bacteria, rapidly placed new chemicals in activity categories. Active chemicals were investigated more precisely by the second method, using spores of *Alternaria solani*, *Venturia inaequalis* or *Botrytis allii*. This method was particularly suitable for investigating groups of related chemicals and effect of formulation on antifungal activity. An auxanographic method of demonstrating interactions between effects of chemicals on fungi was on view. Morphological effects of chemicals on germinating spores of *Botrytis allii* were also shown.

Mr. J. N. Turner had on view the miniature kiln test permitting quantitative comparison of chemicals for control of timber sap-stain and moulding, as used for second-stage evaluation of potential industrial fungicides. Notable features were the use of paired surfaces for treatment versus control comparisons and the high degree of replication achieved within a small space. Tests were seen in progress comparing the British Standards and the Pechmann Schaile methods for laboratory evaluation of timber preservatives. Mycelial mat and soil burial methods for assessing textile preservatives were shown, together with investigations on the effect of leaching and weathering on degree and duration of proofing. Species of fungi responsible for moulding and staining of baled rubber were exhibited.

Miss S. E. Parkinson illustrated with specimens and cultures of the microflora isolated from them the extent and types of damage to leathercloths caused by micro-organisms.

Types of slimes encountered in paper mills were shown, with cultures of bacteria and fungi responsible for their production. Efficiency of control by organo-mercurial compounds depended, *inter alia*, upon the stock, as its composition affected both the type of slime and the absorption and inactivation of mercury by the pulp. Techniques demonstrating bioassay of active mercury in pulp and white-water included two plate methods using *Cladosporium herbarum* and a turbidimetric method using *Lactobacillus helveticus*.

A sensitivity allowing 0·05 μgm. per gm. of active mercury to be detected was achieved.

Methods of determining the resistance of slime organisms to chemicals were also shown.

Mr. I. W. McC. Callan dealt with tests for evaluating chemicals for use as seed fungicides. Laboratory phytotoxicity tests on wheat supplemented glasshouse disease control trials using oats leaf spot (*Pyrenophora avenae*) and pea foot rot (*Pythium ultimum*) for determination of disinfectant and protectant properties respectively. Examples of these standardized replicated experiments were seen. In the experiment garden were demonstrations of the application of seed treatments for controlling seed- and soil-borne diseases, particularly seedling rots, of peas, maize, flax, sugar beet, spinach and cucurbits. The extensive 'rod-row' trials which were seen illustrated a replicated block technique based on single rows used for field assay of chemicals for controlling cereal diseases such as wheat bunt and oats and barley smuts.

Machinery for commercial application of dry and wet seed dressings was demonstrated, and in the laboratory an exhibit of a modification of Machacek's agar-sheet technique showed strikingly the extent of variation of load of toxicant on individual seeds obtainable by varying the seed-dressing formulation and the type of machinery used.

Threshing and winnowing equipment developed for accurate estimation of yields from metre-square cereal sampling plots was also shown.

Dr. J. Stubbs had exhibits of a range of plant diseases which were kept in culture and used for glasshouse evaluation of foliage fungicides. These included *Alternaria solani* and *Phytophthora infestans* on tomato, *Uromyces fabae*, *Botrytis cinerea* and *B. fabae* on broad bean, *Puccinia antirrhini* on antirrhinum, *Erysiphe graminis* on oat, *E. cichoracearum* on marrow, and *Septoria apii* on celery. The methods of using *A. solani* on tomato for detection and measurement of systemic activity were shown, using griseofulvin as example of an active systemic fungicide. They involved absorption by the plant of chemicals applied to roots or leaves. A 0·05 per cent solution of griseofulvin applied to the soil in which small tomato plants were growing afforded complete protection against disease, whereas the same concentration applied to foliage gave only partial disease control on leaves which had been shielded from the spray.

Mr. J. A. W. Turner dealt in detail with the equipment and methods used in the routine *A. solani* test as developed for the first *in vivo* assessment of potential foliage fungicides and for comparison of effects of formulation (for example, of copper and thiram fungicides) on disease control.

Three tomato plants were sprayed with each of a range of concentrations of a chemical under conditions giving standard deposits. After twenty-four hours drying, plants were inoculated by spraying with *A. solani* spore suspension, incubated at 100 per cent relative humidity for a further twenty-four hours and transferred to the glasshouse. Disease counts were made after three days. ED 50 and ED 95 values were obtained graphically from data from three such tests made at approximately weekly intervals. Thiram was used as standard reference fungicide.

Chemicals active against *A. solani* were then examined further, as required, on the range of diseases demonstrated by Dr. Stubbs, before field evaluation commenced.

Mr. C. E. D. Smith described investigations on the control of *Fusarium* patch of turf, storage diseases of gladiolus corms and narcissus basal rot (*Fusarium bulbigenum*).

Techniques for the bioassay of soil fungicides were shown, based on selective isolation of *Pythium ultimum* and *Thielaviopsis basicola* from soils containing the viable pathogens. These were coupled with further experiments to determine persistence of the chemicals in soil and their phytotoxicity. Successful chemicals were tested against clubroot (*Plasmodiophora brassicae*) by a rapid laboratory method, and against *Colletotrichum atramentarium* attacking tomatoes. Demonstrations of this last disease included a character for its early diagnosis and a selective method for isolation of the pathogen.

A tour of the eight-acre experiment garden and trials field enabled further aspects of work described in the laboratories to be seen. These included gladiolus corm and narcissus bulb experiments, potato and tomato blight spraying plots and an orchard for investigation of apple, pear and bush fruit diseases.

R. V. TIPLER

MELLON INSTITUTE

ANNUAL REPORT FOR 1951–52

THE annual report of the President of the Mellon Institute to the Board of Trustees for the year ended February 29, 1952[*], which is published in the *Research Proceedings of the Mellon Institute*, includes a full list of fellowships in operation during March 1,1951–March 1, 1952. Of the Institute's expenditure of 3,835,314 dollars during the year, 727,654 dollars went to the support of investigations in pure science in the Institute's research departments and on nine fellowships, and these projects occupied 117 members of the Institute's staff. In applied science, seventy-seven other fellowships occupied 441 members, and the servicing staff of the Institute numbered 162. New fellowships put into operation during the year are concerned, respectively, with problems of air purification; the development of new chemicals and speciality products, other than fuels and lubricants, used in the operation and maintenance of automobile and aeronautical vehicles and equipment; the technology of glazed and unglazed structural clay products; the combustion of gaseous fuels; the fundamental molecular properties which limit the breaking strength of glass; and the thermostability of active dry yeast.

The Gas Purification Fellowship, which originated in 1939 and was terminated during the year, has led to the development of various new analytical methods, for example, for the rapid determination of hydrogen sulphide and mercaptan sulphur in gases and aqueous solutions, and to a process for reducing the organic sulphur content of coke-oven gas to about 0·5 gm./cu. ft. by scrubbing with an organic base. The Pipe Joint Fellowship, which also has been concluded, has led to the formulation of a product providing adequate thread lubrication during joint make-up and capable of forming a pressure-tight seal in the coupled joints. Other fellowships terminated during the year were the multiple fellowships dealing ith the following topics : polymers, in which during ie tenure of the fellowship processes have been eveloped for lattices of styrene polymers and)-polymers ; the kinetics and mechanism of the ncatalysed condensation of resorcinol with form-dehyde in various solvents ; the efficiencies of light l recovery and of the operation of Koppers's 'Elex' recipitators for removing suspended matter from)ke-oven gas ; and tar products, under which rtensive studies of the rheological properties of itummous compounds led to the development of nproved industrial pitches, sealing compositions, iastics and protective coatings, and fundamental hysico-chemical and rheological studies were made f the nature of coal-tar residual systems.

---

[*] Research Proceedings of the Mellon Institute, 1951–1952 (Annual Report Series No. 39). Annual Report of the President, Edward R. Weidlein, to the Board of Trustees of the Institution for the Fiscal Year ended February 29, 1952. Pp. vi+50. (Pittsburgh, Pa.: Mellon Institute, 1952.)

In the Institute's Department of Research in hemical Physics a detailed study has been made of ie infra-red spectrum of dicyanoacetylene, and its aman spectrum was being studied. Experimental rocedures have been developed for the infra-red udy of inorganic salts, and the spectra of a hundred id sixty salts recorded. Emulsion calibration pro-dures in emission spectroscopy have also been ivestigated, as well as the fine structures of four inforcing carbon blacks, with the view of detecting orrelations between structure and wear resistance id the crystal structure of solid chlorine. In the epartment of Physical Chemistry, four papers on istillation theory have been prepared, and work in us field includes the continued study of the relation etween the concepts of the theoretical-plate and ansfer units and an indefinite number of com-onents. Much time has been spent on the design of small automatic digital computing machine. The epartment of Physical Measurements is continuously ccupied with the determination for publication of ie physical properties of compounds the properties which are inadequately known and of new ompounds.

In the Department of Organic Chemistry, the first art of a study in mental disease, involving the con-ntration of a hyperglycæmic factor from the urine psychotic individuals, has been completed, con-rming the presence of such a factor in the urine of ome schizophrenics. In regard to the utilization of rbohydrates in mental diseases and in diabetes, it is been found that reduction of alloxan with excess ydrogen sulphide in acid solution invariably gives se to dialuric acid and not to alloxantin, but that ie latter is produced if exactly half the theoretical nount of the reducing agent is used. Also, in suit-oly acid aqueous solution (*p*H 1·6), cysteine, utathione and ascorbic acid have no reducing action i alloxan. A series of 4-hydroxy- and 4-amino-eridines have been submitted for testing as imour-inhibiting agents at the National Cancer istitute's Laboratory of Chemical Pharmacology.

Of the fellowships in pure science, the annual port refers particularly to those of the Industrial ygiene Foundation on atmospheric pollution, in hich an automatic smoke filter has been developed ; i industrial dusts, in which the deposition of inhaled articulate matter in the respiratory tract has been udied ; on orthopædic appliances, under which a ew method of constructing 'Bunnell' hand splints r stretching contracted fingers has been worked out, ot-plates intensively studied and the relative merits aluminium and steel for leg traces determined ; id on mine-acid control, which point to control of ie course of natural ground-water entering the mine i the most effective means. Under the multiple fellowship on synthetic rubber, work has been completed on the infra-red study of polyisoprene, which has been found to be a mixture of *cis*- and *trans*-forms in which the latter predominates at all ordinary temperatures of preparation. Fractionation work in dilute solutions has been completed on a synthetic polyisoprene and on polybutadienes prepared at 5 and 50° C., while the response of solid polymers to oscillating stresses and the ultimate strength of cross-linked rubbers are also being investigated. Under the Fellowship on Artists' Materials an attempt was being made to develop a picture varnish, using a synthetic resin, which will be non-yellowing, flexible and readily removable with mild solvents.

Among the applied science fellowships only a few can be mentioned. Promising results have been obtained under the Meter Technology Fellowship with a non-mechanical device for measuring gas-flow, and in work on sulphur, besides the publishing of revised data on the corrosion of steel by sulphur, a comprehensive study has been made of the metering of liquid brimstone. Developments have been made under the Marble Fellowship of a specification for the use of marbles in indoor and outdoor building construction, and, besides wide research on the effects of heat treatment on the physical properties of optical glass, the Optical Glass Fellowship has been expanded to include in its work the experimental heat treatment of larger pieces of finite geometric shape. Considerable progress is reported under the Ceramic Chemicals Fellowship in knowledge of the relative functions of the various components of enamels and in the control of reflectance, colour, colour stability over large ranges of firing temperature, and resistance to acids and alkalis.

Under the Multiple Fellowship on Acid Recovery a promising process has been developed for treating pickle liquor with raw coke-oven gas, while under that on Chemical Storage an improved method was devised for measuring stresses in large steel structures, which has given information on the stress intensities of various tank members, leading to better designs and economies in the use of scarce materials. Most of the work under the Nickel Fellowship has been directed towards studies of the detergent and other properties of oil-soluble nickel compounds with the object of establishing their suitability as lubricant additives, the wetting properties of nickel sulphide on various catalyst supports, and the effect of conditions of precipitation on the characteristics of nickel hydroxide. A Fellowship on Aromatic Anhydrides has continued to be used for the study of catalysts for the manufacture of phthalic anhydride, and under that on monomers an extensive study was made of catalytic dehydrogenation of alkylbenzenes. Geochemical studies under the Petroleum Fellowship have advanced the synthesis of porphyrin degradation products of chlorophyll and hæmin, while further success has been obtained in the sulphurization of olefins, and studies on Fischer–Tropsch catalysts have shown that primary alcohols can be built into higher hydrocarbons in this synthesis. Basic information on the chemical and physical properties of petrolatum is being accumulated by the Fellowship on Petrolatum, and further studies under the Bread Fellowship support the view that the flavour and aroma of salt-rising bread are due primarily to the acid by-products of a symbiotic fermentation of *Clostridium welchii* and *Clostridium tertium*.

In the research of the Insecticides Fellowship, new methods have been developed for the condensation of aldehydes with ketones to give the piperonyl insecticides, and under the Felt Fellowship notable progress has been made in the evaluation of cloth filters and the mechanical napping of fabrics. Under the Fellowship on Match Technology researches have begun on improving the resistance of matches to water and high humidity, the selection of binders, etc. During the tenure of the Fellowship on Organic Synthesis new reactions of diketen with the sodium derivatives of pentadione and acetoacetic esters have been discovered, a study of the effects of chemicals on cellulosic and synthetic fibres has been inaugurated and a series of non-ionic surface agents elaborated, the functionality of which in aqueous solution is not greatly affected by temperature, concentration or the presence of polyvalent metal ions and neutral electrolytes; also real progress has been made in 'Vinylite' resin organosol decorative metal finishes. The development of the 'Stypol' resins, a series of liquid thermosetting materials, has continued under the Protected Metals Fellowship, while work of that on Protective Coatings has placed its main emphasis on the development of coatings for military use and the replacement of scarce materials. Two new types of floor coverings, 'Accotred' and 'Vinoflor', were developed under the Cork Fellowship, and research on synthetic paint-brush bristle was a feature of the work of the Special Fibres Fellowship.

PREPARATION AND PUBLICATION OF SCIENTIFIC PAPERS

It is sometimes customary for scientific societies to give advice and guidance to intending authors as to the preparation of their articles in a form suitable for inclusion in the societies' journals. Usually the advice is limited to some warning about the best method of writing mathematical expressions or to the peculiar layout or spelling adopted by the journal.

A much more comprehensive and instructive manual for intending authors is the revised edition of the booklet "Notes on the Preparation of Contributions to the Institute's Journals and Other Publications" recently issued by the Institute of Physics. The "Notes" were first published in 1931 and were last revised in 1950. No fundamental changes have been made in the new edition; but the opportunity has been taken to make minor corrections and some alterations in acceptable spellings and abbreviations in conformity with recent international and other agreements. Information is given concerning the Institute's publications, the types of contributions acceptable and the conditions of acceptance. Though it is obviously advisable in order to avoid delay in appearance for contributions to conform rigidly with the usages set out in the "Notes", this is not a condition of acceptance.

The "Notes" deal in detail with the preparation, length and cost of text, the form of script and diagrams, the presentation of tabular matter and mathematical expressions and the correction of proofs. Four pages of the booklet are devoted to the proper presentation of circuit, mainly electronic, elements; this seems excessive when it is considered that the Institute's journals do not cater for purely electronic subjects. An interesting reference is to the present average total cost, £10, of each page of text; of a line figure £2 or half-tone £2 10s.; of a typical minor change to a line of type once it is set 5s., or o removing a comma 1s. 6d. This should act as sufficien warning to authors to be extremely careful, to be concise, to avoid unnecessary diagrams and figure and, above all, to revise their manuscripts befor submission for publication.

A short bibliography of dictionaries and books or writing scientific and non-technical literature i included in the "Notes", and the detailed appendixe containing notes and examples of spellings, symbol and abbreviations, the Greek alphabet in Gree and with English equivalents, and printers' mark for correcting proofs, should prove most useful an save authors much valuable time. It is a pity tha in what is otherwise an excellent manual there ar still a few misprints and that the graphical diagra given on p. 13 to indicate the usual faults made b authors is by no means a clear and good example

S. WEINTROUB

DETERMINATION OF PROTEIN CRYSTAL DENSITIES

By DR. BARBARA W. LOW
AND
FREDERIC M. RICHARDS
University Laboratory of Physical Chemistry related to Medicine and Public Health, Harvard University, 25 Shattuck Street, Boston, Mass.

The accurate measurement of protein crystal densities under a variety of conditions is important for the determination of protein molecula weights by the X-ray diffraction method, and for th study of the composition of these crystals. In orde to make best use of the results, it is essential that al the measurements be made on crystals of precisel the same composition. Protein crystals equilibrate rapidly by the loss or gain of water, or by the pene

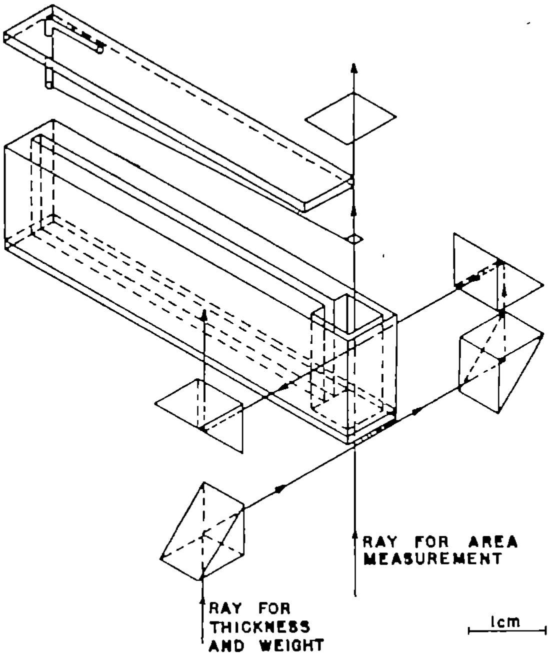

Fig. 1. Schematic diagram of microbalance assembly

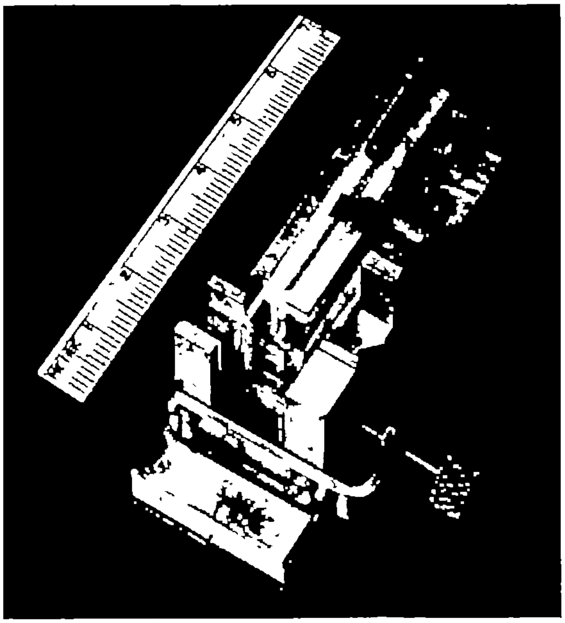

Fig. 2. Perspective view of microbalance

ration of crystal lattices by solute molecules when they are immersed in a media of different composition from that of the mother liquor from which they are grown.

The flotation method developed by McMeekin and Varner[1] for the determination of protein crystal densities and the Linderstrøm-Lang gradient column technique[2] are both capable of accuracies of the order of ± 0·5 per cent when used with large protein crystals (5–25 mgm.) of simple form, the faces of which may be easily wiped free of mother liquor. Both methods are non-equilibrium procedures—an important limitation when crystals are to be measured which contain both alcohol and water as solvents of crystallization. The alcohol dissolves rapidly in the column, or in the flotation liquid. Suitable immersion liquids in which both alcohol and water are insoluble have not been found.

Following an early suggestion of Prof. J. D. Bernal[3], a microbalance was designed and constructed in order to measure the density of a single protein crystal in equilibrium with its mother liquor. The apparent weight of a crystal, supported on a balance pan while immersed in mother liquor, is recorded as the deflexion of a calibrated fibre. The balance is arranged so that the crystal may be observed in two perpendicular directions and photographs taken of the projected areas. From these areas the volume of a well-formed regular crystal may readily be computed.

The density of the crystal may be calculated from the equation:

$$d(\text{crystal}) = d(\text{solvent}) + \frac{\text{apparent weight of crystal in gm.}}{\text{volume of the crystal in c.c.}}$$

The density of the solvent may be measured by any of the standard methods for liquid densities. The density of protein crystals is usually only 10 or 15 per cent greater than the density of their mother liquor. The correction term in the equation above, therefore, is only approximately 10–15 per cent of the total density. For crystals of simple habit weighing between 1 mgm. and 0·1 mgm. in air, the correction term may be measured with a maximum error of about 7 per cent.

The drawing, Fig. 1, is a schematic diagram of the microbalance assembly. The balance consists of a 'Pyrex' glass fibre firmly fixed at one end and bent into a 1–2 mm. horizontal square at the other end. A polystyrene film covering the square acts as a balance pan. The fibre and glass balance case are supported on a suitable brass frame (Fig. 2), the outside horizontal dimensions of which correspond to an ordinary microscope slide. A set of four ¼-in. right-angle prisms are fastened to rotatable mountings permitting accurate alignment for lateral views of a crystal imperfectly aligned on the balance pan. The whole balance assembly is placed on the mechanical stage of a microscope fitted with a 32-mm. metallographic objective, 10 × eyepiece and photomicrographic camera. A net reticule in the eyepiece provides calibration lines on each photograph. The view shown is of a microbalance constructed during the development of the present design. The details of the design, construction and calibration of the microbalance now in use will be described by one of us (F. M. R.) elsewhere.

Fig. 3 shows the photomicrographs from a typical density determination on a crystal of β-lactoglobulin, a preparation used for comparison of this method with other available techniques. The value 1·144 ± 0·066 was obtained with the microbalance, and 1·147 ± 0·003 using the gradient tube method[2] on the same preparation. Measurements indicate that small but real density differences may exist between crystals from different preparations. This could explain the discrepancy between our values and the latest value of McMeekin, Groves and Hipp[4] for β-lactoglobulin ($\rho = 1{\cdot}153 \pm 0{\cdot}002$).

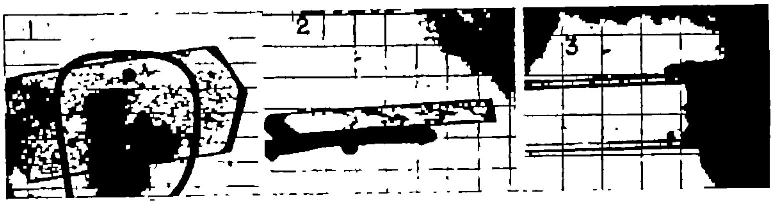

Fig. 3. Photomicrographs for density determination of a crystal of β-lactoglobulin: (1) main face; (2) end-on view, (3) deflexion of balance fibre

The microbalance is at present being used in the study of the density of crystals of β-lactoglobulin and of mercaptalbumin mercury dimer[5] in a variety of suspension media. A minor adaptation of the balance, not shown in Fig. 3, permits the immersing fluid to be changed while a given crystal is kept on the balance pan. Simultaneous volume and density changes may thus be observed. Density, composition and X-ray measurements during controlled swelling and shrinking in a variety of media are being made on these crystals as part of a study of protein crystal permeability.

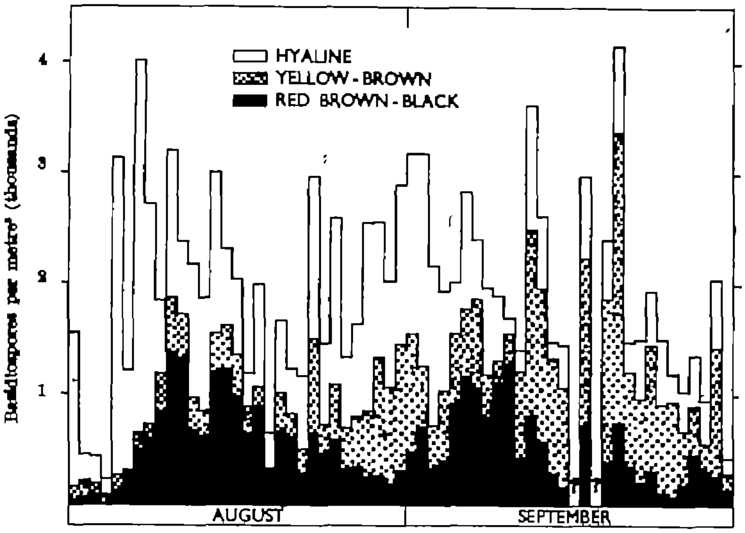
Possible Role of Basidiospores as Air-borne Allergens

THE role of air-borne mould spores in asthma, especially *Alternaria* and *Cladosporium*, has been recognized as the result of the work of Feinberg[1] and Durham[2]. These workers used mainly the gravity slide and Petri dish exposure method to determine the spore content of the air. Both methods are highly selective for different reasons: the former catches larger pollen grains and spores and rarely catches small spores, while the latter only records organisms able to grow on the culture media exposed and therefore selects the more readily growing moulds. Feinberg[1] has stated that basidiospores cause respiratory tract allergy, but data on their occurrence in the atmosphere have been lacking, no doubt because they are not detected by the usual methods.



Daily mean number of basidiospores per cubic metre of air at 2 metres above ground at Rothamsted, August 1 to September 30, 1951 (data obtained with automatic volumetric spore trap)

In studies concerned primarily with fungi pathogenic on crop plants we sampled the air at the height of 2 m. above a potato plot continuously from June 1 to September 30, 1951, using an automatic volumetric spore trap described by Hirst[3]. In this apparatus, which is based on the cascade impactor of May[4], air is drawn through the trap at the rate of 10 litres per minute and the spores are impacted on a 'Vaseline'-coated slide which is moved past a 2-mm. wide slit at 2 mm. per hour. The resulting 24-hr. trace can be scanned under the microscope and the time of deposition of a spore determined with an error of about ± 1 hr. This type of trap is relatively non-selective for particles in the size-range of plant spores, and has been shown to collect and extract from the air not less than 60 per cent of spores as small as those of *Ustilago avenae* (diam. approx. 6·5 μ). It is therefore reasonably efficient for the size-range of basidiospores, and gives a direct measure of spore concentration per unit volume of air.

The number of hyaline basidiospores fluctuates rapidly. Transient clouds of hyaline basidiospores were observed at various times. For example, on July 22, 1951, after eight rainless days with a high concentration of *Cladosporium* and *Ustilago*, a thunder shower with 2 mm. of rain falling between 13.00 and 15.00 hr. washed the air almost free of pollen and spores. Four or five hours after the rain had fallen a high concentration of minute hyaline basidiospores was observed, reaching a maximum of about 30,000 per metre^3 at about 02.00 hr. on July 23, and disappearing almost entirely as the *Cladosporium* cloud became re-established between 05.00 and 08.00 hr. It is possible that these hyaline spores, which are conveniently counted under phase contrast, were liberated by leathery resupinate Agaricales and by Tremellales after wetting by the rain.

The numbers of coloured basidiospores, mainly from Agaricaceae, were remarkably uniform, and were easily counted on the trace with a high-power dry objective. Their concentration in late summer greatly exceeded pollen concentrations recorded by us in June. From August 9 to September 23 the daily mean concentration of coloured basidiospores seldom fell below 1,000 per metre^3 of air (see accompanying illustration). Identification on the trace has not been carried far at present, but spores of species of *Panaeolus*, *Hypholoma*, *Bolbitius*, *Ganoderma*, etc., have been observed.

On dry days the basidiospore concentration showed a peculiar diurnal fluctuation, being lowest in the afternoon and increasing by 3–5 times in the early hours of the morning. This contrasts strongly with other spore types studied which have minimum concentrations at night. The fruit bodies liberate spores at a relatively uniform rate and the higher concentration at night may be due to less rapid dilution of the spore cloud owing to wind velocity and turbulence being lower than during the day.

The exposure of the trap in an arable field adjacent to grassland with trees must be representative of vast rural areas in the temperate regions. The steady high concentrations of basidiospores associated with the seasonal flush of agarics and polypores obviously need investigating in connexion with seasonal asthma.

'Daraprim' Resistance in Experimental Malarial Infections

'DARAPRIM' [2 : 4-diamino-5-(4′-chlorophenyl)-6-ethyl pyrimidine (50-63)] has been described[1] as having high antimalarial activity in laboratory infections of *Plasmodium gallinaceum*, *Plasmodium berghei* and *Plasmodium cynomolgi*. More recently, it has also been tried in the treatment and suppression of human malaria[2]. It has been shown that proguanil-resistant strains of the first two species are sensitive to 'Daraprim' and that 'Daraprim' resistance is not easily produced in *P. gallinaceum* infections[3].

Since the publication of these experiments, further work has resulted in the production of two strains highly resistant to 'Daraprim' : the first, a strain of *P. gallinaceum* in young chicks, and the second, a strain of *P. berghei* in white mice. The *P. gallinaceum* resistant-strain has been previously reported[3] as having only a very slight degree of resistance after fourteen successive passages treated with approximately the minimum effective dose of the drug. Further similar treatment with increasing doses when the previous dose-level proved ineffective has resulted, after forty-two treated passages within a total period of seventy weeks, in a considerable degree of resistance to the drug. The method of infecting and dosing the chicks is similar to that previously described[1].

Using a somewhat different method, a highly resistant strain of *P. berghei* was produced in a much shorter time. The technique, in brief, was to administer to an infected mouse a single dose of the drug when examination of a stained blood film showed 40–50 per cent of the red blood cells to be parasitized ; on subsequent relapse after recession of the parasitæmia, the mouse was dosed for a second time and on relapse the strain was passaged. After two further successive mice had received a single dose each in this way, the strain was tested along with the normal untreated parent strain and proved to be more than twenty times less sensitive to the action of 'Daraprim'. Treatment with one more single dose and three drug courses carried out as described by Goodwin[4] has resulted in a very high degree of drug resistance.

The results of some assays of 'Daraprim' on the parent and treated strains of *P. gallinaceum* and *P. berghei* are shown in the accompanying table.

'DARAPRIM' ASSAYS ON NORMAL AND TREATED STRAINS OF *P. gallinaceum* AND *P. berghei*

Exp.	Species	Strain	Minimum effective dose* of 'Daraprim' (mgm./kgm.)	Degree of resistance*
1†	*P. gallinaceum*	Parent Untreated Treated	0·03 3·8	127
2	*P. berghei*	Parent Untreated Treated	0·04 >0·8	>20
3		Parent Untreated Treated	0·04 13	325

* As previously defined (ref. 3).

† Exp. 1. After forty-two treated passages. Exp. 2. After four single doses. Exp. 3. After a total of five single doses and three drug courses.

Thus it is seen that 'Daraprim' resistance may arise quite quickly, particularly if the drug is called upon to act on a large population of parasites, as in the development of the resistant strain of *P. berghei*. Where, however, the drug is made to act more as a suppressant, as in the technique used for the development of the resistant strain of *P. gallinaceum*, the initial development of resistance is slow and prolonged.

In human malaria the main use of 'Daraprim' will probably be as a suppressant. As in the case of proguanil, where resistance can easily be induced in the laboratory, the problem of 'Daraprim' resistance in the field is unlikely to become a serious disadvantage to its use.

Full details of these and further observations will be published elsewhere.

Detection of Digitalis Glycosides on Paper Chromatograms

Neher and Wettstein[1] have used a solution of antimony trichloride in organic solvent to identify certain steroids on paper chromatograms. Although Jaminet[2] has used an acetic anhydride solution of antimony trichloride for the spectrophotometric identification of cardiac glycosides, he has not reported its use with paper chromatograms. Work in this laboratory has shown that antimony trichloride may be successfully applied to this field.

Reagents at present in use for the detection of cardiac glycosides on paper suffer from several disadvantages : the colour produced by *m*-dinitrobenzene is transient and does not distinguish individual glycosides, hydrochloric acid vapour destroys the paper, while with trichloracetic acid the intense fluorescence produced by traces of gitoxigenin completely masks that of other less reactive glycosides. The antimony trichloride in chloroform (Carr–Price reagent) reported here reacts with less than 0·5 μgm./cm.^{2} of glycoside, giving permanent and distinctive colours in visible and ultra-violet light, while the background remains unaffected. Moreover, if stored in an amber-coloured bottle, the reagent keeps indefinitely.

For the chromatographic development, the glycoside solution was applied to the starting line with an 'Agla' micrometer pipette in a spot not more than 0·5 cm. in diameter. The chromatogram was then developed until the solvent front had run 30 cm. (During development the 'spot' had spread until it

Glycoside	Visible light		Ultra-violet light	
	Colour	Sensitivity	Colour	Sensitivity
Digitoxin	Red-mauve, changing to blue-grey	0·75 μgm.	Red	0·25 μgm.
Gitoxin	Mauve, changing to grey	0·75 μgm.	Apple-green	0·25 μgm.
Digitoxigenin	Pale turquoise-blue	1·0 μgm.	Negative	—
Gitoxigenin	Bright orange-yellow	0·75 μgm.	Bright orange	0·25 μgm.

covered an area of about 2 cm.[2].) The dried chromatogram was treated with a 20 per cent solution of antimony trichloride A.R. in dry, alcohol-free chloroform, and the paper was heated for 3–5 min. at approximately 70° C.

The colours produced are shown in the accompanying table.

On heating, the colour due to gitoxigenin appears first, followed by digitoxin, gitoxin and lastly digitoxigenin, which is also least sensitive to the test. Work in progress indicates that the reagent may be used successfully for the detection of strophanthus glycosides.

I wish to thank the directors of Allen and Hanburys, Ltd., for permission to publish these results.

Pharmacological and Toxicological Actions of Dart Poison used in Malaya

PHARMACOLOGICAL and toxicological actions of dart poison have received a great deal of attention in the past. Among the contributors on this subject were Ridley[1], Chopra and de Premankur[2] and Doebel *et al.*[3]. It was generally assumed that the chief toxic agent in the dart was the digitalis-like substance contained in the latex of the Upas tree *Antiarias toxicaria*, with which some dart poison was known to be made (Burkill[4], and Chen *et al.*[5]). The present communication puts on record some observations of the pharmacological and toxicological actions of a dart poison obtained recently from the Sakais in Perak, North Malaya. A water extract of the dart poison was prepared by dissolving the poison of one dart in 1 c.c. of water. It was filtered before use for the experiment.

The results obtained showed that the dart poison had no stimulating activity on the isolated guinea pig's ileum. It exerted, however, a strong inhibitory effect on the stimulating action produced by histamine and acetylcholine in the same ileum. In the perfused toad's heart, it had a stimulating effect when given in lower concentration and an inhibiting effect when given in higher concentration. Such effects indicated that the dart poison possibly contained two different substances affecting the toad's heart in opposite directions. In higher concentration, it caused stoppage of cardiac action in diastolic relaxation. This was different, therefore, from the effect produced by higher concentrations of digitalis, which usually results in systolic arrest of the heart. The dart poison lowered the blood pressure and increased both the depth and rate of respiration in cats under 'Dial' anæsthesia. This cardiac inhibitory effect on toad's heart and the lowering of cat's blood pressure were not influenced by atropine, thus showing that the active substance which caused these effects was not a choline ester. It was not thought that the dart poison possessed any antihistamine or atropine-like activity, because its inhibitory effect on histamine and acetylcholine stimulation of the guinea pig's ileum lacked specificity. The dart poison also had some curare-like activity, because it inhibited the contractions of isolated rat's diaphragm elicited by stimulating the phrenic nerve. It was estimate however, that this activity was weak, because eac dart contained the equivalent of only 200 μgm. c *d*-tubocurarine, which is not a toxic dose in sma animals.

Toxicological observations made on toads, rats an cats all showed the symptoms of increased respiratio followed soon by asphyxia and death. It was cor cluded that respiratory paralysis was the most likel cause of the fatal results produced by the poiso darts in animal hunting. Since it is improbable tha one substance should have all the actions liste above, it seems right to conclude further that th dart poison contained more than one pharmacologically active substance and that it had been prepared from several sources of material. The fact, moreover, that the main symptoms were very similar t those produced by strychnine suggested that th chief toxic substance was obtained from a plan belonging to the *Strychnos* group, rather than fror the latex of *Antiarias toxicaria*.

Changes in the Distribution of the Intertidal Barnacles in Relation to the Environment

IN previous communications[1,2] the possibility tha changes may occur in the distribution of intertida organisms over a number of years was discussed, ano the established distribution of *Chthamalus stellatu* was extended to include much of the Irish Sea coast line. Further new evidence has come to light showing that while this barnacle may have increased its range and abundance over recent years, it was nevertheless present in the Isle of Man in 1933. A photograph taken by H. B. Moore in March 1933 shows a single individual which appears on close inspection to be *Chthamalus*; moreover, statistical tests based on the size and form of the aperture and the angle of the scutotergal margin show that this must be *Chthamalus* and not *Balanus balanoides*.

However, critical observations on *Balanus balanoides* and *Chthamalus stellatus* during recent years have shown a marked change in their distribution, indicating a general recession of *Balanus* from its southern and western limits, and a corresponding increase in *Chthamalus*. Conclusive evidence for this was first obtained by one of us (A. J. S.) by comparison of recent ecological findings for the Plymouth area with those of Moore[3]. This was confirmed and substantiated by records in the Brixham area (D. J. C.), Barnstaple[4] and Isle of Man (A. J. S.). Since the organisms studied are sessile ones, the changes observed are real changes in the population and the possibility of changes due to migration is eliminated. Most of the regions from which *B. balanoides* is disappearing are those where *Chthamalus* is extremely abundant. However, exclusion by direct competition r rock space is not considered to be the main ctor, since available bare rock is usually present these areas. A second factor might be the recent ncroachment of *Elminius modestus*, which has been arefully followed by one of us (D. J. C.) and which ttles in the intertidal zone with *B. balanoides* in reas where the species co-exist. But in south Devon, *lminius* is still found only rarely outside estuaries; et it is in the regions where *Elminius* is rare, and ot in the estuaries, that we find the most clearly arked depletion of *B. balanoides*. A third possibility the sterilizing effect of the parasite *Hemioniscus alani*, the incidence of which appears to have inreased in *B. balanoides* in south Devon, having been gher than 50 per cent in some areas at Plymouth uring 1950–51; while on January 7, 1950, at Par Cornwall), 47 out of 50 individuals were found arasitized (some with double infection). As *hthamalus* is never infected it is likely that *Elminius*, hich is usually infected to about the same degree s *Balanus balanoides*[6], provides a reserve host for the arasite. Thus a high incidence could be established n the normal host (*B. balanoides*) even to the point f extinction, while the rapid breeding of *Elminius*[6] ight enable the new host to survive. However, this xplanation can be a partial one only, since the ecession of *Balanus* appears to be more widespread han either the incidence of *Elminius* or the present bnormally high *Hemioniscus* infection. It is more ikely that the high rate of infection by *Hemioniscus* s a further indication of the poor condition of B. *balanoides* in those areas, due to some adverse xternal change.

Evidence from the south Devon area suggests that t is the planktonic stages which are most vulnerable. Harris[7] states that at Plymouth settlements of *B. alanoides* fail completely during certain years. At Brixham (Torbay) a heavy settlement of *B. balanoides* was recorded in 1946, a moderate one in 1947, and ather poor settlements in 1948, '49, '50 and '51, articularly so in 1951; yet during 1947–50 ertilization of the eggs in late autumn and release f nauplii in early spring took place apparently ormally; it was the poor survival of the larval tages which accounted mainly for the failure to eplace the normal mortality of the population. A milar occurrence appears to have taken place beween 1949 and 1951 in the Isle of Man, where at ne locality the numbers of *Balanus* were reduced y as much as 75 per cent; and at the same time he small population of *Chthamalus* increased by up o 50 per cent. Although a proportion of the recent ncrease in *Chthamalus* may be a secondary result f the decreasing spatfall of *Balanus*, which thus frees ore rock for settlement, this cannot be wholly the ase in the Isle of Man or in the estuaries of south Devon, since in both places an increase in *Chthamalus* has occurred mainly above the *Balanus* zone.

Taken together, the changes in distribution of *Balanus* and *Chthamalus* suggest the influence of some general climatic factor, such as the recent succession of mild winters or a rise in average temperatures during several years. It is difficult to envisage other factors operating so generally and yet capable of affecting both species. The mode of action need not necessarily be a direct or obvious one; it might, for example, cause abnormalities in the early embryonic development of *Balanus* and render many of the larvæ ultimately non-viable; it might also result from changes in the phytoplankton succession[8]. An understanding of the mechanisms by which such changes operate is clearly of great importance, since if they are climatic in origin, as we suggest, they would be expected to have an influence on many other marine organisms, including probably some of economic value.

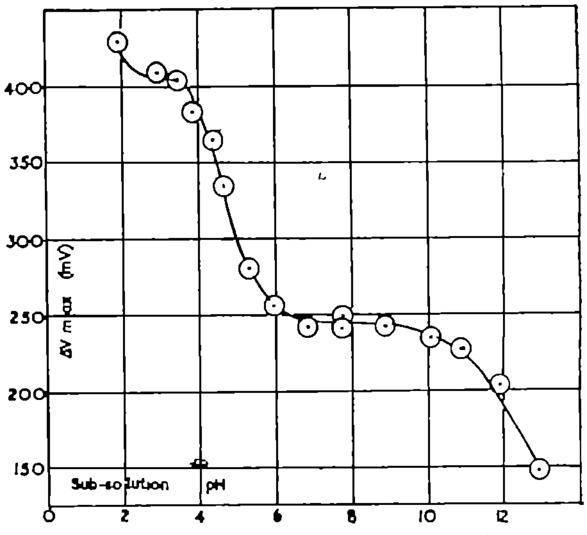
Ionization of Bovine Serum Albumin Monolayers

IT has long been known that the surface electrical potential of a protein monolayer at the air/water interface is dependent on the pH and the nature of the ions present in the aqueous sub-solution. There is no record, however, of a comprehensive investigation of the variation of protein surface potential with the pH of the sub-solution. This information, were it available, would be a 'titration curve' of a protein monolayer, and would shed light on the nature and extent of the ionizing groups of the protein when spread as an insoluble monolayer. We wish to report preliminary results of such a surface titration curve for the protein bovine serum albumin.

The accompanying graph shows the surface potential of a bovine serum albumin monolayer as a function of the pH of the aqueous sub-solution. This solution contained 0·01 N sodium chloride and was buffered by 0·005 M (H_2CO_3/$NaHCO_3$/Na_2CO_3). The presence of sodium chloride ensured a stable insoluble monolayer, in addition to minimizing any ionic charge effects due to the ionizing buffer salts over the pH range 2·0–13·0.



Surface titration curve of insoluble monolayers of bovine serum albumin, spread on 0·005 M bicarbonate buffer containing 0·01 N sodium chloride

The technique adopted was as follows: 'Armour' crystallized serum albumin (10·0 mgm.) was dissolved in, and spread from, distilled water (20·0 ml.) containing 1 per cent ethanol. Simultaneous surface pressure and surface potential *v.* area measurements were made, using standard compression isotherm procedure for insoluble monolayers. For a given subsolution, the surface potential varied with the state of compression of the monolayer. At the collapse point, however, the surface potential became constant and attained its maximum value. This maximum value (ΔV max.) was taken as characteristic for the protein monolayer under the appropriate conditions of pH and ionic strength of the subsolution. Surface potentials were reproducible to ± 5 mV.

From the graph it can be seen that appreciable changes in surface potential (ΔV max.) occur in the pH ranges 3·5–6·5 and 10·0–13·0. The former change is clearly due to the ionization of carboxyl groups, whereas the latter change is due to the neutralization of the cationic amino groups of the protein. The general shape of the curve is similar to that obtained by acid-base titration of the native globular protein dissolved in aqueous solution. Some differences are evident, however. For example, we note that, compared with results obtained in bulk solution[1], the curve is markedly displaced towards higher pH values, thereby raising the apparent pK_a values of the dissociating groups. Such a result has already been observed with monolayers of long-chain fatty acid[2]. Furthermore, it appears that the neutralization of the iminazole $\overset{+}{=\mathrm{NH}}$— group of histidine is not being shown by changes in surface potential. The reason for this is not yet clear. However, it may very well be that these amino groups are not available in the surface when the protein monolayer is highly compressed.

The great advantage of the present technique is that it permits the study of the ionization of a protein which is only available in small amounts, 10 mgm. being ample for such an investigation. Further work on other proteins and high-molecular weight polypeptides is being actively pursued and will be discussed elsewhere in due course.

Our thanks are due to Dr. J. H. Schulman for valuable advice and interest in this work.

Comparison of Ganglionic Blocking Agents

IN a series of papers, Shaw *et al.*[1–3] have submitted evidence which indicates the presence of two pharmacologically distinct groups of cells in sympathetic ganglia, one group of cells giving rise to vasoconstrictor fibres and the other to vasodilator fibres. It was also mentioned that the cells in the superior cervical ganglion did not react quantitatively in the same manner to all paralysants[3]. Consequently, a number of ganglionic blocking agents have been tested on the superior cervical ganglion of cats.

A condenser-type strain gauge was used to recor the contraction (and relaxation) of the nictitatin membrane, and a photoelectric method was used t record the constriction (and dilatation) of the bloo vessels in the ear. A test stimulus of constan repetition-rate, for a fixed time, was applied to th preganglionic fibres. This stimulation of the cervica sympathetic trunk resulted in contraction and con striction of the nictitating membrane and ear vessel respectively. All paralysants were administered b direct injection into the common carotid artery, th blood supply of the ganglion being left intact.

Two series of measurements were made for al drugs: (*a*) the duration of complete paralysis o the nictitating membrane and of the ear vessels (*b*) the time to complete recovery of these two tes objects.

In general, we have found that after paralysi the responses differ, in that the time taken by th nictitating membrane to show a first response differ from the time taken by the ear vessels.

	Duration of paralysis (min.)		Duration to complete recovery (min.)	
	Ear vessels	Nictitating membrane	Ear vessels	Nictitating membrane
D-Tubocurarine chloride 0·2 mgm./kgm.	22	10½	30½	29½
Dimethyl tubocurarine iodide 0·3 mgm./kgm.	12½	8½	30	12
Pentamethonium iodide 3·5 mgm./kgm. (C5)	5	11	31	39
Tetraethyl ammonium bromide 7 mgm./kgm. (T.E.A.B.)	7	13½	10	25½
'Pendiomide' 2 mgm./kgm.	8	8½	16	16

The accompanying table shows the averaged times from about six experiments for each paralysant. For D-tubocurarine and dimethyl tubocurarine, the ear vessel response is more affected than is the nictitating membrane, the reverse result being the case for pentamethonium iodide and tetraethyl ammonium bromide. In the case of N,N,N′,N′-3-pentamethyl-N,N′-diethyl-3-aza-pentane-1,5-diammonium dibromide (CIBA 9295, 'pendiomide')[4] there is practically no difference. Although differences are apparent in the times to complete recovery, they are not as marked as the paralysis times.

Whether the differential response obtained is due to the blocking agents acting at the ganglion, or peripherally, or at both these sites, we cannot as yet say. Stimulation of the post-ganglionic fibres from the superior cervical ganglion while the ganglion is still paralysed will be carried out to give an indication as to where the paralysants are causing the differential effect. Guyton and Reeder[5], and also Paton and Zaimis[6], have shown that different ganglia vary in sensitivity to a particular blocking agent. So far as we know, both the ear vessels and the nictitating membrane are innervated directly from the superior cervical ganglion, that is, only one ganglion is involved; therefore it is unlikely that the differential results obtained can be explained on the basis of ganglion sensitivities.

It appears that the response of the nictitating membrane itself does not give a precise account of the action of the various ganglionic blocking agents used. When testing an agent for paralytic activity on ganglion transmission, it may not be sufficient o employ only one test object. As animal experiments are usually carried out prior to clinical testing, would be best if tests for ganglionic paralysants esembled more the purpose for which they were sed in man, namely, to prevent vasoconstriction esulting from active vasoconstrictor fibres.

The neuromuscular blocking agent tri-(diethylminoethoxy)-1,2,3,benzene triethiodide (gallamine riethiodide—'flaxedil') was also administered and, s expected, failed to block the ganglion except in ery large doses. However, in about 40 per cent of he experiments it brought about a potentiation of he ear vessel constriction on stimulation and had ery little effect on the nictitating membrane response lose, 7 mgm./kgm.). As Mushin *et al.*[7] have found hat 'flaxedil' does not possess anti-choline esterase ctivity, the potentiation cannot be explained on hese grounds. As yet we have no explanation for he result.

2,5-*bis*-(3-Diethylaminopropylamino)benzoquinone-is-benzyl chloride (WIN 2747) has been shown by Hoppe[8] to be a neuromuscular blocking agent. As n the case of 'flaxedil', it failed to block the superior ervical ganglion except in large doses. A marked eduction of the nictitating membrane contraction was found to occur with doses of 3 mgm./kgm., when the pre-ganglionic fibres were stimulated. At he same time, this dose of WIN 2747 was found to ave very little effect on the ear vessel constriction.

Molecular Weight of Glycogens determined by a Light-scattering Method

THE use of light-scattering methods for the letermination of the molecular weight, size and shape of macromolecules has become of increased importance n recent years. Studies already made include those n cellulose acetates[1], polystyrene and synthetic olymers[2], and several proteins[3,4]. The influence of odium chloride on the size and shape of a detergent–rotein complex has recently been investigated using light-scattering method[5]. The application of this nethod to the measurement of the molecular weight of several glycogens is reported in this communication.

The relation between the molecular weight M, of he solute, and the turbidity τ, of the solution, is iven by the well-known equation[6,7]

$$\frac{H.C}{\tau} = \frac{1}{M} + 2B.C, \qquad (1)$$

where C is the concentration of the solute in gm./ml., nd H and B are constants.

The glycogens examined were supplied by Dr. D. J. Bell, and had unit-chain lengths of 11–13 glucose radicals (determined by potassium periodate oxidation[9]). The light-scattering apparatus used has already been described[8]. It was calibrated in terms of bovine serum albumin, a molecular weight of 69,000 being assumed for this protein[4]. Refractive index increments were determined using a Rayleigh type interferometer. Curves of $H.C/\tau$ *v.* C for the various glycogens are shown in the graph, and the molecular weights, calculated by extrapolating these curves to zero concentration, are given in the accompanying table.

Source of glycogen	M	I_{45}/I_{135}
Rabbit liver	$6 \cdot 8 \times 10^6$	1·15
Rabbit muscle	2·8 ,,	1·0
Cat liver	10·0 ,,	1·40
Fœtal sheep liver	14·8 ,,	1·10
Tetrahymena pyriformis (ref. 9)	9·8 ,,	1·90
Ascaris lumbricoides	8·8 ,,	1·17

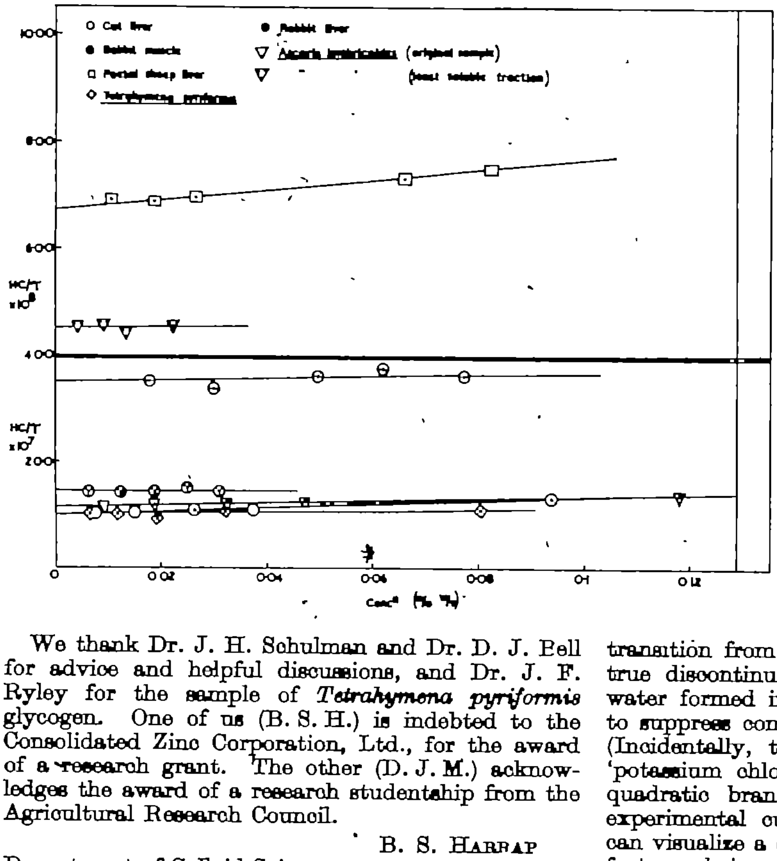
Considerable diversity is found among the results of different workers for the molecular weights of various glycogens[10]. The results for rabbit muscle and *Ascaris* glycogen may be compared with those obtained by Bell *et al.*[11] on the same samples of glycogen, from sedimentation-diffusion measurements. The present value of $2 \cdot 8 \times 10^6$ for rabbit muscle glycogen agrees well with their value of $2 \cdot 6 \times 10^6$. There is a marked disparity between the value of $8 \cdot 8 \times 10^6$ for *Ascaris* glycogen and the value of $0 \cdot 7 \times 10^6$ obtained by Bell *et al.* However, examination of their sedimentation diagram for *Ascaris* shows considerable broadening of the 'peak' in the direction of higher molecular weight units. Since molecular weights calculated from turbidity data are 'weight average' values, the presence of small amounts of material of high molecular weight will result in the values obtained by this method being much higher than the molecular weight of the main fraction of the sample.

The dissymmetry of light-scattering shown by some of the glycogens (see table) may be due to the presence of fractions of high molecular weight. Rabbit muscle glycogen, which gives the most symmetrical peak in the sedimentation diagram[11], shows no dissymmetry; furthermore, fœtal sheep liver glycogen, which has the highest molecular weight of any glycogen reported in the table, shows a negligible dissymmetry. This point may be further illustrated by reference to *Ascaris* glycogen, which shows a disparity between the molecular weight values obtained from sedimentation-diffusion and light-scattering measurements. This glycogen originally showed a dissymmetry (I_{45}/I_{135}) of 1·15–1·20. After fractional precipitation with ethanol at a concentration of 40 per cent, a fraction (3 per cent by weight) was obtained which had a molecular weight of $22 \cdot 5 \times 10^6$, and a dissymmetry of 1·45. This clearly shows that small amounts of material of relatively high molecular weight may be present in the glycogen samples. For this reason, none of the values given in the accompanying table has been corrected for dissymmetry and must be regarded as giving an order of magnitude only for such highly polydisperse systems.

H. Staudinger[12] has measured the molecular weight of various glycogens using the relation:

$$K_L.M = \tau_{sp}, \qquad (2)$$

where K_L is a constant for the wave-length used and τ_{sp} is the specific turbidity (that is, the absolute turbidity of a solution containing 1 gm. solute per litre). This equation is equivalent to equation (1), if there is no deviation from the van't Hoff osmotic pressure law, that is, if $B = 0$. Staudinger determined K_L from the turbidity of samples of glycogen the 'molecular weights' of which had been determined by osmotic pressure measurements. His values for rabbit liver, rabbit muscle and cat liver glycogens of $5 \cdot 2 \times 10^6$, $1 \cdot 9 \times 10^6$ and $6 \cdot 9 \times 10^6$ respectively are considerably lower than the values reported in our table. It must be noted, however, that the samples of guinea pig liver glycogen used by Staudinger for calibration were likely to be polydisperse. Since osmotic pressure measurements give 'number-average' molecular weights, the values obtained in terms of this standard would tend to be lower than the 'weight average' values normally given by turbidity measurements.



We thank Dr. J. H. Schulman and Dr. D. J. Bell for advice and helpful discussions, and Dr. J. F. Ryley for the sample of *Tetrahymena pyriformis* glycogen. One of us (B. S. H.) is indebted to the Consolidated Zinc Corporation, Ltd., for the award of a research grant. The other (D. J. M.) acknowledges the award of a research studentship from the Agricultural Research Council.

Effect of Withdrawal-Rate on Second Explosion Limits

In a recent communication, Baldwin and Precious have directed attention to the effect of withdrawal rate on the hydrogen–oxygen second limit. Sinc they found this effect to be present in clean vessel and absent in vessels coated with potassium chloride they favour an explanation which connects it with the participation of quadratic branching in the reaction. During our examination of the hydrogen oxygen reaction[2], we have also had occasion to stud this phenomenon. Our own observations suggest tha the effect is not directly connected with the presenc of quadratic branching and support the alternativ explanation, namely, that the net branching facto is reduced to zero by the products formed during the initial stages of the explosion

While agreeing that the effect i most pronounced in vessels of low chain-destroying efficiency (clea 'Pyrex', boric oxide) we have also observed it with many other surfaces (potassium chloride, potassium hydroxide, etc.) at higher temperatures where the slow reaction is o the same order, but where significant quadratic branching is still no detectable. The effect is negligible in very rich mixtures and increase markedly as the hydrogen–oxygen ratio decreases, thus becoming greatest in the region where the slow reaction and quadratic branching contribution are at a minimum. We have also found a similar phenomenon to occur in carbon monoxide–oxygen explosions, but have not been able to find any indications of quadratic branching in this reaction.

This alternative explanation is supported by the work of Von Elbe and Lewis[3], who showed that the transition from slow reaction to explosion is not a true discontinuity, and that it is possible for the water formed in the initial stages of the explosion to suppress completely its subsequent development. (Incidentally, those observations were made in a 'potassium chloride' vessel under conditions where quadratic branching is not evident.) From the experimental curve of Baldwin and Precious, one can visualize a condition in which the net branching factor is being decreased by the production of water at the same rate as it is being increased by the slow reduction of pressure. Such a system would stay on the brink of explosion right through the explosion region without suffering anything more than a vigorous slow reaction.

Two observations confirm this view. In the hydrogen–oxygen reaction it was noticed that if the withdrawal-rate was made so slow that the mixture would not normally explode, and if at any time after crossing the limit the evacuation-rate was increased by a sudden twist of the tap, then explosion followed within a period of ½–3 sec. Secondly, with moist carbon monoxide–oxygen, one is fortunate in being able to 'see' the presence of a slow reaction by the blue glow emitted. On crossing the limit at a fast rate, the blue glow suddenly increases to a brilliant uncontrollable flash; but with sufficiently low evacuation no such transition occurs, the blue low rising to a constant value throughout the xplosion region. If evacuation is stopped at any tage after crossing the limit, the blue glow slowly ades. A further slight evacuation brightens it up omentarily, and this process can be repeated many imes.

The phenomenon leads to experimental difficulties nly when observing the second limits of very weak ixtures. To obtain any explosion at all in this egion, the rate of evacuation must be faster than is esirable for accurate manometer reading, and also nder these conditions the explosion lag, as indicated bove, must become a significant source of error. his uncertainty tends to prevent the accurate etermination of the constants *c* and *F* of the explosion limit equation[2], values from the second limit eing much greater than those derived from the first. urthermore, the unknown error due to explosion ag might well be the cause of the observed but unexected temperature dependence of the third-body oefficient *a*[3], since the necessary rate of withdrawal ncreases both with ratio of oxygen to hydrogen and ith temperature.

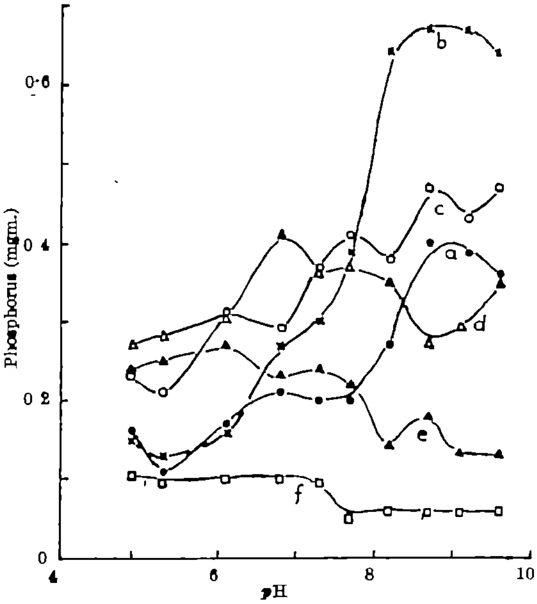
Zinc, Ionic Equilibrium and Phosphatase Activity

CONTROVERSY has centred around the nature of he active groups influencing the activity of alkaline hosphatases of higher animals[1]. In a recent comunication[2], I suggested on the basis of results btained with the alkaline phosphatase of the fungus *enicillium chrysogenum*, *Q*-176, that the activity of he enzyme is influenced by both zinc and magnesium ons and that the relative proportion in which these ons existed in an active state determined the *p*H f optimum activity.

I have further investigated this problem with lkaline phosphatases prepared from ox kidney and ntestines by the method described by Thoai, Roche nd Roger[3], and the results obtained by me go to upport my earlier observations that both zinc and magnesium ions and the relative concentration in which they are present exert considerable influence n the activity of the enzyme. From the accompanyng graph, it will be apparent that while cyanide t higher concentrations inhibits activity at all the H's tested, the enzyme shows increased activity on he acid side at intermediate concentrations of cyanide nd on the alkaline side at very low concentrations. I ave also observed that by the addition of magnesium ons to the enzyme inhibited by 0·002–0·004*M* cyanide, ctivity was increased on the acid side to a considerbly greater extent than at other *p*H's, whereas a imilar addition of zinc resulted in the restoration f activity at all the *p*H's at low, and on the alkaline ide at intermediate, concentrations of zinc. In both cases there was an optimum concentration at which the activity was maximum, higher concentrations of zinc especially bringing about general inhibition of activity at all *p*H's.



Effect of varying concentrations of cyanide on ox kidney alkaline phosphatase at different *p*H's. Each substrate contained neutralized sodium cyanide at the following concentrations: (*a*) nil, (*b*) 0·0002 *M*, (*c*) 0 0004 *M*, (*d*) 0 001 *M*, (*e*) 0·002 *M*, (*f*) 0 004 *M*

The complete inhibition of activity of the enzyme at all the *p*H's on the addition of cyanide at the higher concentrations and the effect of addition of zinc in increasing concentrations to the cyanide-inhibited enzyme in restoring the activity first at all the *p*H's and thereafter at the more alkaline *p*H's show that zinc ions are necessary for activity at alkaline and acid *p*H's. Other heavy metals, such as manganese, iron or cobalt, had no appreciable effect in restoring the activity of the cyanide-inhibited enzyme. It is well known that magnesium ions are necessary for full activity of the enzyme on the alkaline side, and I have observed that this is so only when zinc ions are also present, for the cyanide-inhibited enzyme is only partially activated by magnesium on the alkaline side.

From these findings, I suggest that there is no entity like 'acid' or 'alkaline' phosphatases, but that by merely changing the equilibrium between the prosthetic ions or groups of the enzyme, activity can be established at any *p*H desired. Admittedly, the phenomenon as it applies to enzymes in higher animals is more complex than the one observed for the enzyme in *P. chrysogenum*, *Q*-176. The results of this investigation will be published in due course.

Quantitative Spot Test on Filter Paper and Examples of its Application

WHILE, so far, the spot test on filter paper, developed by Dr. F. Feigl and his co-workers, has been used exclusively for qualitative purposes, we have discovered a method for the estimation of various substances by using circular filter papers and the solvents which are commonly used in paper partition chromatography.

The procedure is as follows. At the centre of a circular filter paper a small drop is placed of the solution of the sample containing a few milligrams of the substances under examination. After drying, solvent for partition chromatography is dropped in small portions (5–10 drops per min.) from a capillary tube on to the centre of the paper, thus causing development of the chromatogram. The substances contained in the sample mixture develop gradually to accurate concentric circles forming partition zones. For this manipulation a desiccator or Wit's filter bottle is used, in the bottom of which there are placed a small volume of partition solvent to saturate the air in the vessel with the vapour of the solvent used and a Petri dish containing the same solvent on which the filter paper (of about 11 cm. diameter) is placed. The development is complete when solvent has spread to a circle 7–8 cm. in diameter (about 30–40 min.). By using circular filter paper, we can work with much larger amounts of material in a shorter time than by the usual method of paper chromatography. Quantitative estimation is usually made by calculating the area of partition zones on the filter paper. It may, however, be effected, in general, more exactly by cutting up the paper, extracting and then applying colorimetry or densitometry by ultra-violet light to the extract. The chromatograms thus obtained are similar to those produced by Rutter's method[2]. Our procedure was developed in the past few years independently of his report.

The following are a few examples of the application of quantitative spot tests on filter paper.

(1) *Estimation of methanol and ethanol.* In a preceding paper[3], we reported a method for the detection of methanol, in which the potassium xanthogenates derived from a methanol–ethanol mixture by adding carbon disulphide and potassium hydroxide are submitted to paper partition chromatography using butanol saturated with 5 per cent sodium bicarbonate solution. Applying the technique outlined above, the ethyl xanthogenate is discernible as an outer circle, while that of methanol is located in an inner zone, as shown by ultra-violet light. The chromatogram is dried, cut up into its partition zones and the latter extracted by 5 per cent sodium bicarbonate. After sixty seconds from the addition of freshly prepared Grote's reagent (twice normal concentration) the estimation can be made electrophotometrically.

(2) *Estimation of R-acid and G-acid.* Both acids are apt to be produced in admixture as intermediates in the manufacture of dyes, and their separation was considered hitherto as a difficult problem. Applying our new technique to the development of the mixture of both acids (using butanol saturated with a 5 per cent solution of sodium bicarbonate) and following the process under ultra-violet light, the partition zones (outlined with pencil) are extracted with 5 per cent sodium bicarbonate solution. By addition of the diazonium salt of naphthionic acid, there are produced red dyes, which can be estimate electrophotometrically.

Note added in proof. A somewhat similar techniqu of circular paper chromatography has been describe recently by Giri and Rao[4].

Conductance in Non-aqueous Solutions

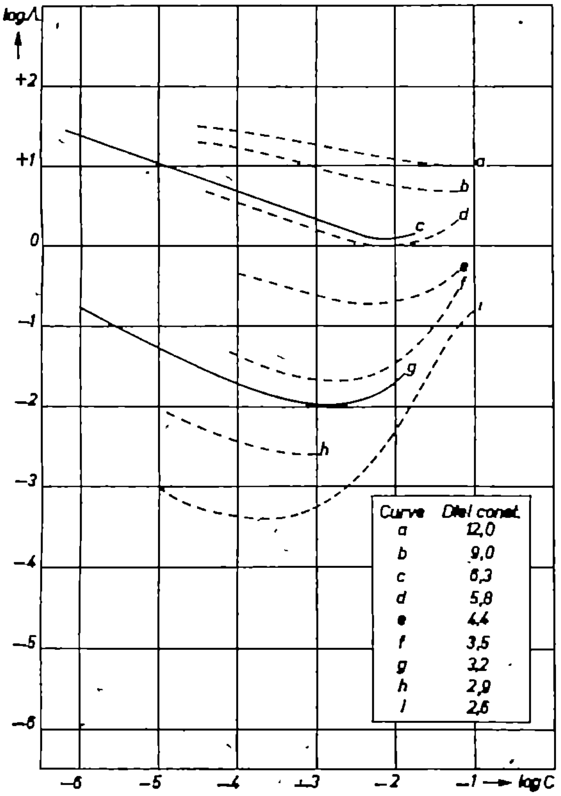
IN the extensive work of Fuoss, Kraus an co-workers[1] on the conductivity of solutions in medi of widely divergent properties, these authors ar led to the conclusion that, viscosity excepted, ther is no specific influence due to the solvent, but tha the dielectric constant of the medium alone determine conductivity data.

Since Fuoss and Kraus do not consider acid media measurements of conductance of solutions in som organic acids are in progress in this laboratory t test the theory mentioned above. The followin materials were used: 100 per cent glacial acetic aci (solvent-conductance 0·4–0·8 × 10^{-8} mhos) obtaine by fractionating 97 per cent acetic acid; 100 pe cent propionic acid (solvent-conductance less tha 3×10^{-10} mhos) obtained by fractionating a C.P product; tetraethylammoniumpicrate (melting poin 255·5° C.) prepared from silver picrate and tetraethylammoniumiodide. The conductance was measured with a Jones bridge[2]; a cathode-ray oscilloscope served as detector of current-minimum. A frequency of 1,000 c./s. was used. The conductanc cells were designed according to Jones and Bollinger[3] using non-platinized platinum electrodes. Th measurements here described were made with 125-c.c. cell (cell constant 0·00965). In preparin the solutions, all precautions were taken to preven contact with the air.

Measurements were carried out at 25° C. wit solutions of tetraethylammoniumpicrate in glacia acetic acid ($D = 6{\cdot}25$) and propionic acid ($D = 3{\cdot}15$ respectively, covering a wide range of concentrations The accompanying graph shows the logarithm of th equivalent conductance (Λ) as a function of lo molality (C). The dotted lines are from data o Fuoss and Kraus[1] on tetra*iso*amylammoniumnitrat in mixtures of dioxane and water.

Although Fuoss and Kraus worked with a somewhat different salt (both salts, however, are rathe strong electrolytes), it is obvious that our value fit in very well with theirs. So we may conclud that, also in the acid media, the dielectric constan is the determining factor for the conductanc phenomena.

With the aid of the extrapolation method o Shedlowsky[4] the following constants, corrected fo solvent conductance, can be given for tetraethyl ammoniumpicrate in acetic acid: Λ_0 (equiv. conduct



t infinite dilution) = 29·9 ohm^{-1} cm.^{2}. K (dissociaion constant) = 1·63 × 10^{-4}.

The values for propionic acid cannot yet be given.

This work is being carried out with solutions of different electrolytes in formic acid (D = 58), acetic acid, propionic acid and mixtures of these solvents.

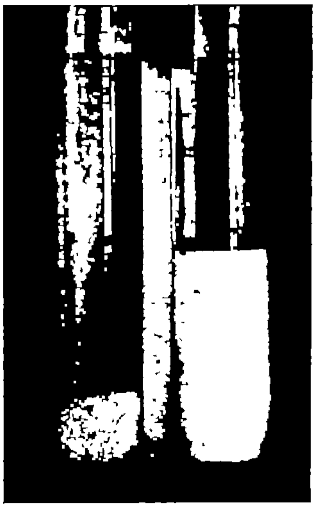
Micro-spherical Aggregation of Barium Sulphate

During an investigation of the influence of certain organometallic compounds on the velocity of sedimentation of inorganic materials in non-aqueous media, a phenomenon has been observed which does not appear to have been previously recorded. Precipitated barium sulphate, free from soluble salts, as prepared for X-ray examinations, and containing no addition agent, was dried for several days at 110° C., and shaken with pure dry benzene in a stoppered Nessler tube in an automatic shaker. The shaking was carried out at the rate of five oscillations per second, the tube being shaken longitudinally, with a displacement of 2 in. After 24 hr. the solid had aggregated completely into spheres of 1–0·5 mm. in diameter, as shown in Fig. 1(*a*). The sediment volume was slightly less than that of the lightly tamped dry solid, indicating a close degree of packing of the spheres. If the tube was then subjected to very violent and irregular manual shaking, the spheres broke up to form a flocculate (shown, after 24 hr. standing, in Fig. 2). On further regular shaking for 30 min., the spheres re-formed as before.

It is tentatively suggested that this phenomenon may be due to the fact that barium sulphate has a hydrophilic surface (method of Davis and Curtis[1]), and that it will consequently tend to aggregate so as to present to the benzene the minimum surface per unit volume. In this respect the phenomenon can be regarded as in some way analogous to the formation of drops of one liquid when shaken in another. It is to be expected that this form of aggregation would not occur in a solvent which is miscible with water, so the experiment was repeated with 1 : 4 dioxan. The suspension formed was very fine, and settled very slowly (about 4 cm. per hr.); Fig. 1(*b*) shows its appearance after standing for three days. Even after prolonged shaking, no sphere-formation was observed. In diethyl ether, however, the barium sulphate formed spheres, though somewhat larger and more easily broken up than those from the benzene suspension.



(*a*) (*b*)
Fig. 1

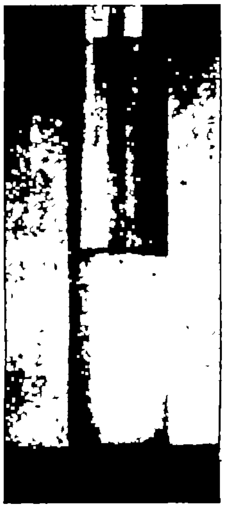


Fig. 2

In each of the tubes (Figs. 1 and 2), which were of equal diameter, the total volume of solid and liquid was 50 ml., and the weight of barium sulphate was 10·00 gm.

A further experiment was carried out, using basic lead carbonate, which is known to have an 'organophilic' surface[2]. On shaking this with benzene there was, as might be expected, no sign of sphere-formation.

This work is being continued, and will be reported in detail elsewhere.

Gravity Observations in a Borehole

GRAVITY surveys are widely used as a method of geophysical exploration. A knowledge of the densities of the underlying rock layers is necessary for the interpretation of the results. While the density of samples may be determined in the laboratory, the only really satisfactory method of finding the bulk density is by gravity observations in a mineshaft or a borehole. The information obtainable by this method has been discussed by Smith[1], who has also suggested further uses for the observations.

With this object in view, a gravimeter has been constructed and some preliminary tests have been made in an oil borehole belonging to the Anglo-Iranian Oil Co. at Eakring, Notts. The gravimeter is similar in principle to that previously described by me[2], but various points in the design have been improved and modified to suit the limited space available in a borehole.

Fundamentally, the instrument consists of a thin filament held in tension by a weight; the transverse vibrations of the filament control the frequency of an electronic oscillator. The weight is prevented from rotating about an axis along the filament by means of thin strip hinges and, between observations, may be held in its normal position by a system of clamps operated by an electric motor. The instrument and the thermostat which controls its temperature are mounted in gimbals inside a pressure-tight steel container, which also contains electronic apparatus for maintaining the oscillations of the filament and operating the thermostat. The external dimensions of the container are 5 in. external diameter by 8 ft. in length. The apparatus for recording the frequency of vibration of the filament is at the surface, and is electrically connected to the gravimeter by the 4-core cable which supports the instrument in the borehole.

The vertical gradient of gravity may have three main component parts, assuming that the rock layers penetrated are uniform, horizontal and of large lateral extent. The first is the normal free-air gradient; the second component, of magnitude $4\pi G\rho h$, is due to the attraction of the rock layer penetrated, h being its thickness, ρ its density and G the gravitational constant. The third component, which may not be present, is the gradient due to a buried anomalous mass. The presence of such a mass may usually be inferred from a surface gravity survey around the borehole, or from the abnormal vertical gravity gradient near the mass. The numerical values of the free-air term of the vertical gradient is 9·41 milligals per 100 ft.; the second term has a value of 6·40 milligals per 100 ft. for rock of density 2·5 gm./c.c. If no anomalous mass is present, the resultant gradient is 9·41–6·40 = 3·01 milligals per 100 ft. If the accuracy of the gravimeter is ± 0·7 milligal at each of two stations spaced 100 ft. apart, that is, ± 1·0 milligal in the difference, the accuracy of the second component of the gravity gradient will be ± 1·0 in 6·40, or ± 15 per cent. This will lead to a similar error in the deduced density. The accuracy can be improved by increasing the separation of the stations, if the rock layer is sufficiently thick, or by improving the accuracy of the gravimeter.

The field-test of the gravimeter took place during two days, February 2 and 3, 1952. The first, while showing up various defects in the gravimeter, did not give reliable measurements. The results of the second day's working are shown graphically in Fig. 1.

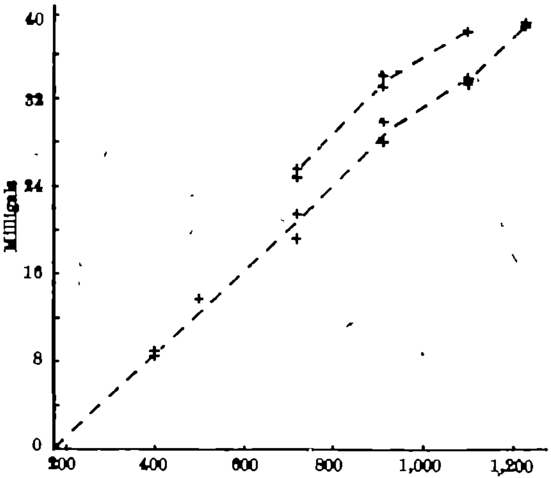

Fig. 1. Variation of gravity with depth

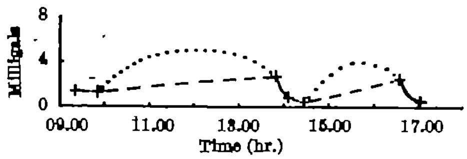

Fig. 2. Zero drift; February 3, 1952

Two runs were made, each starting from a depth 178 ft., proceeding to 1,226 ft. and returning to 178 ft stopping at each level marked on the graph in eac direction. The 'zero' readings of the gravimeter 178 ft. are also shown (Fig. 2), and it may be see that, whereas the initial rate of drift is reasonabl low, the zero frequency at the end of each run different from that at the beginning. The disturb ance of the frequency returns towards the origin value with a time constant of the order of ½ hr. It thought that this is probably a thermal effect, an if so, the true drift was probably as shown by th dotted line. As experimental verification has not y been obtained, the results given below have bee calculated on the assumption of a linear drift shown by the dashed line.

A surface gravity survey gave no indications of subterranean anomalous mass and so no anomalou gradient need be suspected. The probable error of single observation with the gravimeter, derived fro repeated observations at each level, is about ± 0 milligal. This error, which is much larger than w experienced in the laboratory, is attributable several causes. The gimbal system was not perfe and this caused some scatter of the readings at ea depth. A reversible jump of 4·6 milligals was o served at several stations; this is presumably d to a small piece of dirt alternatively remaining eith on the weight or the clamps (see Fig. 1).

Samples of chippings of about 0·1 cm. side we available from the borehole and, although these m not be fully representative of the formations, th densities were measured and averaged over 200- intervals. The error of determination of the densit is estimated at ± 1 per cent.

In the accompanying table, the densities obtain from the chippings, together with those from t gravimeter, are given.

At first sight it would appear that the rock form tions are not saturated with water. Final conclusio

ge (ft.)	300–500	500–700	700–900	900–1,100	1,100–1,200
vi- eter nsity	2·23±0·08	2·23±0·08	2·14±0·15	2·65±0·15	2·15±0·20
p- ngs nsity ct)	2·40	2·37	2·25	2·50	2·25
y)	2·25	2·17	1·97	2·33	2·0

ould not be drawn, however, as the effect of assum- a linear drift of the 'zero' frequency is to indicate ower density than would be obtained if the altern- ve drift curve were adopted.

I should like to thank the Anglo-Iranian Oil Co., d., for financial support during the period of search, for permission to publish this communica- n and for allowing me to use their borehole and providing a suitable cable and winch for the periments. I should also like to thank the chair- n and members of the Paul Instrument Fund mmittee for a grant enabling the gravimeter to built, Prof. A. O. Rankine for his interest in the rk, and Mr. B. C. Browne and Dr. R. I. B. Cooper, the Department of Geodesy and Geophysics, mbridge, for their help and encouragement during e investigation.

Electromagnetic Momentum and Newton's Third Law

The following simple relations[1] between electro- agnetic momentum, Poynting's vector of energy w, and mass–energy equivalence do not appear to ve received general recognition in connexion with e validity of Newton's Third Law when applied to ectromagnetic forces.

If the dielectric medium is free space, so that there no matter present to take reactive forces, we sup- se that the energy represented by the Poynting ctor, $\vec{\epsilon} \times \mathbf{H}$ (rationalized M.K.S. units), moves with e velocity of light and also has mass of amount m r unit volume of the field. Suppose also that its omentum per unit volume is $\mathbf{D} \times \mathbf{B}$ (where $\mathbf{D} = \kappa_0\vec{\epsilon}$, $= \mu_0\mathbf{H}$, $\kappa_0\mu_0 = 1/c^2$), and consider a unit area of rface normal to the direction of energy flow. Then the rate at which energy passes through this surface $|\vec{\epsilon} \times \mathbf{H}|$, it follows that the amount of *moving* ergy per unit volume of the field is $W = |\vec{\epsilon} \times \mathbf{H}|/c$. s momentum is mc, so if this is to be equal to $\times \mathbf{B}|$, we must have:

$$m = \frac{|\mathbf{D} \times \mathbf{B}|}{c} = \frac{|\vec{\epsilon} \times \mathbf{H}|}{c^2} = \frac{W}{c^2},$$

hich is the mass–energy relation.

Whenever the total 'ponderomotive' force on an ectromagnetic system is not zero, it is equal to the olume integral of $-\frac{\partial}{\partial t}(\mathbf{D} \times \mathbf{B})$ taken over the hole of the dielectric in which $\mathbf{D}$ and $\mathbf{B}$ exist. is therefore balanced by the volume integral of $(\mathbf{D} \times \mathbf{B})$, the time-rate of change of the total ectromagnetic momentum. The interpretation is clearly that this represents the rate of change of ordinary mass-momentum of the energy which is moving about in the changing field, and that the 'equal and opposite' reaction to the unbalanced ponderomotive force is borne by the energy photons.

Newton's Third Law is thus reinstated if the mass of the field energy is taken into account. The theorem applies both to radiating and to non-radiating systems. A simple example of the latter is to be found in the case of a charged particle moving with uniform velocity through a constant-current toroidal coil.

Screw Dislocations in Pyrite

In the course of an investigation into the surface structure of a wide range of mineral crystals, the results of which were reported to the Mineralogical Society in March 1951, a number of screw dislocations were observed on the cube faces of one crystal of pyrite, FeS_2. Fig. 1 shows a single screw dislocation; while Fig. 2 exhibits a pair of screw dislocations of opposite sense, which ultimately form an almost closed step-line. The crystal was photographed using a metallurgical microscope, with bright-field illumination, and the surfaces were not silvered. Under these conditions, the very high visibility of the steps forming the main spiral patterns indicates that the layers are multimolecular. This point is further substantiated by the presence of some much thinner layers between the main steps. Examples of screw dislocations with a Burgers vector greater than unity, often considerably greater, have already been reported for cadmium iodide[1], silicon carbide[2], and muscovite[3].

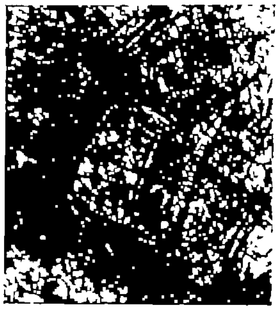

Fig. 1 (× 35)

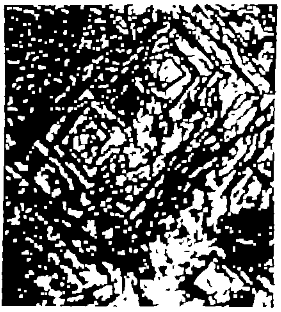

Fig. 2 (× 35)

The incompleteness of the spiral patterns in Fig. 2 appears to be due to the separation of the thickest layers into several thinner ones in some places.

Note added in proof. A paper on the surface structure of crystals is to be published in the *Mineralogical Magazine*.

FORTHCOMING EVENTS

(*Meeting marked with an asterisk * is open to the public*)

Monday, September 8—Tuesday, September 9

FARADAY SOCIETY (at the University of Toronto, Toronto, Canada).—General Discussion on "The Reactivity of Free Radicals".

Wednesday, September 10

INSTITUTE OF PETROLEUM (at Manson House, 26 Portland Place, London, W.1), at 5.30 p.m.—Mr A. W. Paxton: "Mud Control in the Fields of the Iraq Petroleum and Associated Companies".*

Thursday, September 11—Friday, September 12

MIDLANDS SOCIETY FOR ANALYTICAL CHEMISTRY (at the University, Birmingham), at 9.30 a.m. each day.—Symposium on "Analytical Chemistry".

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

CHIEF SUPERINTENDENT OF THE LONG RANGE WEAPONS ESTABLISHMENT, Salisbury, South Australia, to undertake the overall direction and control of the L.R.W.E. which includes certain laboratories at Salisbury and ranges near Woomera—The Senior Representative, Department of Supply, Canberra House, 87 Jermyn Street, London, S.W.1 (September 15).

PRINCIPAL SCIENTIFIC OFFICER at the Propulsion Research Laboratory, Salisbury, South Australia, for supervising a chemical section for research and investigations related to materials for rocket motors and rocket propellants—The Senior Representative, Department of Supply, Canberra House, 87 Jermyn Street, London, S.W.1 (September 15).

SENIOR SCIENTIFIC OFFICER at Royal Aircraft Establishment outstation at Woodbridge, to study problems arising out of the marshalling and landing of aircraft, design, conduct and evaluate full-scale experiments to define principles of methods for achieving high rate of safe handling using electronics or other flying aids; prepare functional specifications for components of such systems—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting A 226/52A (September 15)

HEAD OF THE DEPARTMENT OF MECHANICAL AND ELECTRICAL ENGINEERING—The Principal, Wigan and District Mining and Technical College, Wigan (September 17).

LECTURER (high academic and research qualifications essential) IN CHEMISTRY—The Clerk to the Governors, Chelsea Polytechnic, Manresa Road, London, S.W 3 (September 19).

ASSISTANT LECTURER (temporary) IN PHYSIOLOGY—The Registrar, The University, Sheffield (September 20).

DEMONSTRATOR IN ZOOLOGY—The Registrar, The University, Leeds 2 (September 20).

RESEARCH OFFICER (Plant Pathologist) IN THE DIVISION OF PLANT INDUSTRY, Canberra, for plant physiology investigations relating to plant growth—The Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2, quoting No. 3059 (September 27).

LECTURER (with a university degree in either metallurgy, chemistry or chemical engineering, and experience in industry) IN THE DEPARTMENT OF CHEMICAL ENGINEERING at the University of Sydney—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (September 30).

LECTURER IN VETERINARY PHARMACOLOGY—The Registrar, The University, Liverpool (September 30).

SENIOR LECTURER IN ANIMAL PRODUCTION at the University of Queensland—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (September 30).

VETERINARY OFFICERS and RESEARCH OFFICERS IN THE MINISTRY OF AGRICULTURE AND FISHERIES—The Secretary, Civil Service Commission, 6 Burlington Gardens, London, W.1, quoting No. 130–173/52 (September 30).

SENIOR LECTURERS or LECTURERS (Grade II) IN PHYSICS, CHEMISTRY AND BIOLOGY, at Kumasi College of Technology, Gold Coast—The Secretary, Advisory Committee on Colonial Colleges, 15 Victoria Street, London, S.W.1 (October 1).

UNIVERSITY LECTURER IN BOTANY (with special responsibility for teaching and research in plant bacteriology)—Dr. S. Smith, Department of Zoology, Downing Street, Cambridge (October 1).

RESEARCH OFFICER IN THE DIVISION OF PHYSICAL AND ANALYTICAL CHEMISTRY of the National Chemical Research Laboratory in Pretoria, to supervise the analytical work of the Laboratory and carry out research work in the field of inorganic chemistry—The South African Scientific Liaison Officer, Africa House, Kingsway, London, W.C.2 (Pretoria, October 8).

HERBARIUM ASSISTANT (First Assistant on the staff of the Bolus Herbarium), University of Cape Town—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (October 15).

PROFESSOR OF STRUCTURAL ENGINEERING at the University of the Witwatersrand, Johannesburg—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (October 25).

PHYSICIST (with a first- or second-class honours degree) in a section engaged on a long-term study of the mechanisms of drainage and drying as applied to the papermaking machine—The Director, British Paper and Board Industry Research Association, St. Winifred's Laboratories, Welcomes Road, Kenley, Surrey.

RESEARCH INVESTIGATOR for interesting metallurgical investigat of a new welding problem, and a JUNIOR CHEMIST to assist in rou and special analyses of steels and light alloys and the determinat of dissolved gases by a high-vacuum technique—The Secretary, Brit Welding Research Association, 29 Park Crescent, London, W.1.

SENIOR SCIENTIFIC OFFICER at Experimental Flying Establ ment near Salisbury, to take charge of section dealing with comp design and testing of aircraft instruments and test methods, to ad on methods of measurement of physical quantities in aircraft fli and to give guidance to aircraft industry in methods for maintena and calibration of instruments used in acceptance test flying— Ministry of Labour and National Service, Technical and Scient Register (K), Almack House, 26 King Street, London, S.W.1, quot A.232/52A.

TECHNICAL ASSISTANT (university or similar qualification in ch istry desirable) as secretary to committees dealing with various aspe of chemical standardization—The Establishment Officer, Brit Standards Institution, 24 Victoria Street, London, S.W.1.

APPLICATION OF SCIENCE IN INDUSTRY

THE Messel Memorial Lecture, "The Strategy of Science", which Sir Henry Tizard delivered to the Society of Chemical Industry in Aberdeen on July 9, is above all a challenge to constructive and penetrating thinking about the balance of research effort in Britain, its orientation and distribution as between industry, government and the universities, and the development of technical and technological education. It indicates, rather than asks, the questions which should be put and answered before policy in such matters is determined, and in this way provides the atmosphere in which the recent report of the Advisory Council on Scientific Policy in presenting the report of its Committee on Manpower, or the more recent survey of scientific and industrial research in British industry of the Federation of British Industries, should be examined. It lends strong support to some of the recent representations made to the Lord President of the Council by the Parliamentary and Scientific Committee (see *Nature*, August 16, p. 267).

Sir Henry's address (*Chemistry and Industry*, August 16, p. 788) is, in fact, largely an exposition of the theme that large endowments afford no assurance that research will be wisely and profitably directed. Money can be wasted on research as easily as on anything else, and his discourse stems essentially from a typically shrewd comment made to him many years ago by Lord Rutherford on learning of a large endowment for research received by a physics laboratory in the United States: "We haven't any money", remarked Lord Rutherford, "so we've got to think"; and the core of Sir Henry's address lies in his insistence that it is imperative for us to select the right targets in research and development. We cannot afford to waste first-class men on second-class objectives. We must think out the objectives that really matter, and then be bold and adventurous. Without adventure in industry Great Britain is doomed to decay.

Sir Henry took a sombre view of Great Britain's economic position; he thinks that the present state of instability is likely to persist. He went so far as to suggest that lack of industrial effort and failure to apply the right policy are due at least in part to insufficient realization of the serious state of affairs. This in turn is due, he believes, to the neglect of political leaders to explain frankly to the working population the dangerous condition of the economic structure of Britain. So far from that being one of temporary instability due to the War or to the mistakes of politicians since the War, for many years before the Second World War we had been in a state of unstable equilibrium, exposed to the force of any adverse world event outside of our own control. He believes that the ultimate solution of the economic problem of Great Britain will only be found in a better distribution of the population throughout the British Commonwealth. Even as an agreed policy, such a redistribution would take a long time to effect.

Meanwhile, we must endeavour to balance our trade as best we can by exporting what the world wants and needs, in the face of severe competition. This obviously depends largely on the good judgment with which science is applied to industry, and especially on the swiftness with which action is taken to secure the appropriate balance between science and technology. Sir Henry did not conceal his impatience for action rather than talk.

It is from this point of view that Sir Henry urged that strategy is more important than tactics. By the strategy of science he means the art of so directing the application or advance of science as to ensure the most rapid progress of society, or of knowledge. Tactics, on the other hand, is the procedure or skilful devices calculated to gain the strategical end, or in another word, 'research'. The strategy of the application of science to industry must depend not only on available tactical skill and knowledge, but also on the economic circumstances of different countries. It demands constant fresh and flexible thinking about our economic circumstances and searching inquiry as to our reasons and objectives.

Curiously enough, although it is apparent that Sir Henry believes that some redistribution of population is required as a long-term policy—and such redistribution has obvious implications for both the industrial and the economic strategy of Great Britain—he does not here consider specifically their bearing. The strategy he advocates for science is clearly to be based on fresh thought about all issues, but in the first place he suggests we should concentrate on the effective application in industry of existing knowledge. As in his presidential address to the British Association four years ago, he urges that this is our first need. We are still paying too much attention to fundamental research in industry, and too little to the need for development and skilled application. A more severely practical view of industrial research is essential if we are to recover economic stability, and Sir Henry quoted with approval the article on the role of science in the British economy in which Dr. R. L. Meier developed this theme two years ago. We must concentrate our efforts, he said, on those projects which will help to restore the balance of trade, directly or indirectly, as quickly as possible, and be careful to avoid dispersing them over too wide a field. Not until we have an overall balance of trade in our favour for at least five successive years can we afford, Sir Henry thinks, to spend much time, thought or money on developments which, however desirable in a perfect world, are not vital to our existence. Neither the scientific prestige of the nation nor the quality of scientific education is likely to suffer by such a policy of strengthening our technology rather than expanding our science.

Sir Henry's note of urgency in this connexion reinforces the representations made to the Lord President of the Council by the Parliamentary and Scientific Committee on July 28; but there is a further point which is causing Sir Henry some concern. Referring to the bearing of judgment on the selection of the right objectives as a prelude to any redistribution in our research effort, and the consequent difficulties in reaching agreement as to the targets that matter, he pointed out that we have still to secure concerted action. No common policy, for example, has yet been agreed by the nationalized fuel industries, and even in the most scientific of British industries, the chemical industry, there is reason for disquiet. The highest executive positions in such industries have long been occupied by well-known men of science or technologists; and the various companies which make up, for example, the chemical industry, would pass all ordinary tests of technical or financial efficiency with ease. Nevertheless, the industry is apparently not succeeding in competing in the world market. The British share of world trade in chemicals has been slowly declining since 1913, when the condition of the chemical industry was very different, and in spite of the high standard of chemical science in Britain and the large expenditure of the industry on research.

Sir Henry does not believe that this can be attributed to the quality of chemists engaged on research in the industry being lower than in other countries. Nor does he appear to blame faulty judgment on the part of the directorate of the industry—though some chemists may think he is less than fair to the British industry in his remarks regarding the exploitation in other countries of the discoveries of British industries. Still less does he attribute it to inadequate financial resources. In defence research and development, he remarks, we do not spend one-fifth of what is spent in the United States but we have held our own, and have often led the way.

Shortcomings, in Sir Henry's view, appear to be mainly due to slowness of production from the prototype to the full scale. For this, two factors are chiefly responsible: first, a fiscal policy which discourages enterprise and adventurousness, and second obsolete social attitudes and trends in the educational field which hinder as many boys of outstanding ability as is desirable in the national interest from entering on a scientific career. This second is a consideration which is fundamental to the development of higher technological education.

Sir Henry's forthrightness on the first point is highly significant, coming from one who has recently retired from the chairmanship of both the Advisory Council on Scientific Policy and the Defence Research Council. Possibly his release from official responsibilities may leave him freer to urge publicly views based on his own wide experience, which may yet require a large measure of public support to secure their adoption by official establishments not yet awake to the implications of the strategy of science. Meanwhile, his position with the National Research Development Corporation has not inhibited him from voicing his misgivings as to the possible adverse effect of such experiments on the adventurousness of industry. Sir Henry recognizes that the Corporation has important functions to fulfil. He sees none the less that, in discharging them, there is a real danger that industry may be encouraged to expect the nation to carry the financial risks of development.

Sir Henry's misgivings on this score are justified by reference to the engineering industry. He main-ains that in recent years defence research and evelopment at the cost of the taxpayer, rather than rivate enterprise, have provided the chief stimulus o British engineering of the highest quality. In his udgment, more money is spent by the taxpayer on ngineering development than is spent by all the ngineering industries put together, and he fears that here is danger of this spreading, and of the taxpayer aving to take risks which formerly were taken by rivate enterprise.

The strategy of science in Britain, accordingly, ust take account of the distribution of research etween industry and government institutions, as ell as between industry and the universities. There re important questions to be considered before llocating the execution of a particular project that rightly judged essential to the national interest s between industry or a government institution; here the project is carried out may not prove to be secondary matter. It may affect vitally the stimuation or encouragement of the skill, originality and nterprise which, whether in engineering or in other elds, must be allied to research, development and esign if we are to increase our share of the world's rade. Sir Henry has already formed the conclusion hat the springs of enterprise in Britain are running own, and that unless industry is able and allowed o increase its capital expenditure, and does it wisely, t is idle for scientific men to complain that their iscoveries are exploited elsewhere.

Our strategy must thus first and foremost encourage nterprise, and as one element it must break with he present practice of leaving the responsibility for eciding whether any branch of industry shall spend nything on new ventures largely with Civil servants n government departments. A thorough and thoughtul analysis of Government expenditure on civilian esearch, particularly in relation to production, and ts organization, might also yield some useful tactical uggestions. But the main threat to industrial nterprise in Britain lies in taxation policy, and no trategy will be adequate which does not insist on he removal of financial as well as other elements hich discourage adventure in industry or in science. or should it be forgotten that financial restrictions nd controls can also discourage enterprise and lead o far-reaching delays and frustration, apart from a erious waste of scientific and technical man-power. uch consequences are sufficiently serious to warrant he wish that every existing restriction or control ould be reviewed and no new one promulgated apart rom the critical and constructive thinking implied Lord Rutherford's remark, "We haven't any oney so we've got to think".

Sir Henry's strategy of science demands above all reative and critical thought and a spirit of adventure. o develop skill and originality, to foster adventurousess and sound judgment, to select the right objectives nd to distribute wisely our limited resources of an-power and materials are the main elements; nd some clear indications are given as to the tactics be used, notably in the field of technical and echnological education, where Sir Henry's impatience r action is manifest. Here he calls for a determined effort to overcome a difficulty referred to by the Advisory Council on Scientific Policy and discussed at a greater length in a second article by Dr. R. L. Meier, "Research as a Social Process", in the *British Journal of Sociology* last year. Sir Henry condemns the kind of intellectual snobbery which discourages many an able man from studying technology at a university; our tactics must be calculated to break down such snobbery and all other attitudes which discourage a sufficient proportion of the ablest minds of each generation from entering on careers in science and technology, or moving freely within those spheres whether in industry, the universities or the departments of State. Dr. Meier in his second article points out that the evolution of the organization of research has been in conflict with the traditional values of the man of science, and the distribution of our research effort has been determined by social status more than is commonly realized. An adequate strategy of science must take full account of such factors and their effect on specialization, as well as on the communication between groups. It must provide the tactics for enticing more of the ablest intellects, who would otherwise limit their activities to science, into responsible positions in industry and in applied research, and for encouraging the training in our educational system of those capable of forging links between the different disciplines, thus carrying further the type of co-operation that has proved outstandingly successful in what is known as 'operational research'.

Scientific workers and industry in general are much indebted to Sir Henry Tizard for his stimulating and suggestive Lecture. Their response to his imperative and urgent call to action as well as to thought could do much to impel Government action in some fields where it has been long overdue.

BIOCHEMISTRY AND BIOLOGY OF ANTIMETABOLITES

A Study of Antimetabolites

By D. W. Woolley. Pp. xiii+269. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1952.) 40*s*. net.

THE publication of "A Study of Antimetabolites" is most timely, and, when it is written by a master of the subject like Dr. D. W. Woolley, of the Rockefeller Institute for Medical Research, it is certain to receive a most hearty welcome. The subject has had a slow and difficult birth from the time Ehrlich, in developing his experiments on immunity and, later, on chemotherapy, propounded the idea of 'receptors', and so emphasized that chemical specificity is a dominant factor in cell life. This was followed in the enzymic field of study by the discoveries of Michaelis (1910–14) and his collaborators that some inhibitors are similar in chemical structure to the products of the reaction. In Great Britain the extension of the idea of antagonism of enzymic action to analogues came to the fore with the work of Quastel and Wooldridge in 1927, when they described the competitive inhibition of succinic dehydrogenase by malonic acid, a structural analogue of the substrate of the enzyme. Other work which supported this conception came gradually to light, but the great modern interest and eagerness to examine the hypothesis began seriously when Woods in 1940 extended the subject to the chemotherapeutic field by reporting that the bacteriostatic action of sulphanilamide and related sulphonamide drugs was reversed completely and competitively by *p*-amino benzoic acid, which later was shown to be an essential metabolite of bacteria.

Since that time, Dr. Woolley and many others have found numerous instances of inhibitors of cellular reaction based on this form of interference, and the subject of antimetabolites must now be regarded as one of the fundamental hypotheses of biochemistry. It has shed light on living responses other than those of an enzymic and chemotherapeutic nature, such as hormonal interaction, pharmacological antagonism of drugs and vitamin deficiency diseases. Thus the close similarity between the structure of testosterone and œstrone suggests a basis for the well-known antagonism of androgens and œstrogens in higher animals, and for the regulation of sexual characters by a balanced reaction between these substances. In the sphere of vitamin activity, we find evidence of structural antagonism in the fact that typical signs of vitamin B_1 (aneurine) deficiency in mice can be called forth by pyrithiamine, and that glucoascorbic acid can elicit a condition in mice similar to that seen in scurvy in man. Dr. Woolley himself has been particularly interested in the pellagra-producing effect of maize; and, although he has not isolated the essential active antagonist to nicotinic acid, he has given reasons for believing that there is such a substance and that it may well be related to β-acetyl pyridine, which certainly is an antagonist to the antipellagra vitamin. It is to be hoped that this problem will prove more straightforward than that of the rachitogenic action of oatmeal, where it was found that the struggle for calcium by phytic acid and phosphoric acid was decided by the presence of vitamin D.

While Dr. Woolley has assembled the essential facts—up to 1950—which have poured as a stream into the crucible, and has described and discussed them in their proper place, he has emphasized throughout that the hypothesis will require modification as the subject develops. This critical and philosophic attitude, and the realization that the antimetabolite hypothesis is only serving as a support for the acquisition of new facts which will in time require new scaffolding is one of the many attractive features of the book. It is already clear that there are, at present, many inexplicable difficulties, and that some of the reactions described are undoubtedly more complicated than is now apparent; but the great merit of the theory is that it will continue to stimulate greatly the acquisition of new knowledge of biochemical reactions and, it is hoped, of biological processes themselves.

Now that Dr. Woolley has put his hand to this particular plough, we look to him not only to discover many new facts and the generalizations that may be necessary to account for them, but also to continue to enlighten and delight us with further editions of this book as the subject unfolds. Biochemists and biologists will undoubtedly take the opportunity of profiting by the book, and of appreciating the new vistas now opened up by this intellectually pleasing hypothesis so well presented as a complete story by Dr. Woolley.

E. MELLANBY

A PHILOSOPHY OF MANAGEMENT

The Art of Administration

By Ordway Tead. Pp. xvii+223. (London: McGraw Hill Publishing Co., Ltd., 1951.) 32s.

NO reviewer could do better than echo Stuart Chase's commentary on Mr. Ordway Tead's latest publication: "this is a fine thoughtful book obviously the climax of a lifetime of study, meditation and active participation in the art and science of administration". For more than a generation Mr Tead has been high among the classical authors in the American literature of industrial management interested primarily in its philosophical aspects and concerned always to urge the practical executives to be more alive to a depth of fundamental thought on which to rest their practice.

In this new study, Mr. Tead takes up again his favourite themes of the essentially human core of management and of its bearing on the everyday working of the principles of democracy. Here, he has always believed, lie the major problems of the twentieth century. Several chapters take up this theme from various points of view, examining not only the ways and means of getting "leadership in action" within a democratic framework, but also many of the difficulties to be encountered. Perhaps for the first time Mr. Tead is now willing to recognize that "in a democracy people have to be only as free as they want to be". Effective leadership is always the key to efficient action—and without any intention either of cynicism or of paradox, one may posit as the central principle of democracy the institution o the selected authority that can govern the many to the satisfaction of all. How this is done is the content o Chapter 9, "Administration as Democratic Leadership".

In the narrower context, Mr. Tead's thesis i admirably summed up in a passage in the foreword contributed by Mr. L. Appley, president of the American Management Association: "We, the contemporaries of the age", he writes, "are coming to realise that management is a career and that its effective exercise is based upon the understanding o human motivations, sensitivity to the means o sensing human responses, and skill in supplying human satisfactions". What is involved in such skills forms the main substance of this book—the skills o leadership, not peculiar to the industrial world though the analysis is here carried out in relation to the management of industry. A most useful chapte is the one entitled "Human Nature in Action" revealing in a very practical way the raw materia with which every executive at every level has to work. How the leader has to apply his skills to thi material is fully studied and the lines of approach se out for his guidance. He is warned, in anothe valuable chapter, on "Personal Power and Authority in Administration", of the dangers and pitfalls tha will beset him because of his own frail human makeup: "the exercise of personal power over or with others is one of the ways in which we get a sense o worthwhileness, of registering with others, of maximising our egos". This line of thought is profoundly reminiscent of Mary Follett twenty-five years ago.

This is not a text-book of management practice it is more valuable than that, and more unusual. It philosophical character may, perhaps, not make quite the strong appeal in Great Britain which the autho has commanded in the United States, but its though and teaching are of immense value to the immediate ɔds of Britain. For British readers, the choice of le is unfortunate, for it will serve to revive a ıtroversy that has latterly been laid to rest. The ɔcess that Mr. Tead has been studying is now almost ıversally called 'management' over here, and the ɔtagonists of 'administration' are fast dwindling. ır is there any more a divergence about 'art v. ence': the process of management is now recog- ːed as a skill that partakes of each. Mr. Tead ɹuld have served his cause the better by calling his ok, say, "A Practical Man's Guide to Leadership".

E. F. L. Brech

ADVANCED TEXT-BOOK OF ORGANIC CHEMISTRY

ıemistry of Organic Compounds

ɣ Prof. Carl R. Noller. Pp. ix+885. (Philadelphia ıd London: W. B. Saunders Co., 1951.) 35s.

ꓷCHOLARSHIP, much teaching experience and an appreciation of the worth of organic chemistry ıve gone to the making of this book. Its author, ofessor of chemistry at Stanford University, ts out his subject-matter in forty-two chapters. ʌo of these are mainly devoted to theory; the st, as well as the customary elementary matter, ɔal with more advanced topics, such as heterocyclic ımpounds, synthetic rubber, fluorinated aliphatic ımpounds, amino-acids, steroids, organic peroxides, ıd compounds of phosphorus, of silicon and of etals. The contents are intended for the first two ɔars of a course for university students.

Prof. C. R. Noller is aware that the ever-increasing ass of facts of organic chemistry can be seen as an dered array and intelligently studied only if a ıowledge of the underlying physical principles and modern ideas of molecular structure have been so astered that they can be applied. He is likewise ʌare that many a student has not the mathematics command necessary for the latter task: he there- re makes use of bold simplification. Thus, of the ʌo approaches to the structure of a molecule, he ɐfers to begin with that of the molecular orbitals ıd to introduce these by the geometrical method ɔpularized in Great Britain by Prof. C. A. Coulson. mplification is also effectively used in Chapter 7, hich is devoted to an exposition of reaction mechan- ɯ, a subject on which the author lays much nphasis because of its integrating value. Here, aders meet the brilliant teacher. First, he recalls ɪe factors concerned with equilibrium; then by eans of diagrams, logical argument and simple athematics, he proceeds to explain the different echanisms. Several illustrative examples both of nic and of free radical mechanisms are discussed at ınsiderable length. Once again Prof. Noller directs tention to the work of British chemists, singling ıt for mention C. K. Ingold and his collaborators ıd paying a special tribute to the late Prof. A. ɐpworth. The theoretical principles established in ɐse two chapters are extensively applied in the ɔdy of the book. Thus, the chapter on aromatic tro compounds has several pages on the mechanism substitution in the benzene nucleus and includes ɪe modern theory of nitration.

The forty well-written chapters of descriptive atter abound with distinctive characteristics, but ɔnsiderations of space permit the recording of only few examples. For example, Chapter 17 gives a concise, but in itself complete, account of stereoisomerism and includes a masterly exposition of the determination of the configurations of the sugars, while Chapter 31, on dyes, opens with a discussion of the subject of colour and of its relation to chemical constitution.

An exceptionally full index (forty-five pages), historical footnotes, frequent and absorbing digressions on economic aspects, and devices to aid study (such as the use of two sizes of type and the numbering of the carbon atoms in big molecules) do not complete the list of attractive features. In short, this stimulating and inspiring book should afford the student just the help he needs. "Noller" will undoubtedly take a high place among the great instructional books of organic chemistry.

G. Fowles

POCKET ATLAS OF THE SWISS FLORA

Taschenatlas der Schweizer Flora

Mit Berücksichtigung der Ausländischen Nachbarschaft. Von Eduard Thommen. Zweite, vermehrte Auflage. Pp. xvi+309. (Basel: Verlag Birkhäuser, 1951.) 13.50 francs.

THIS booklet, of a convenient pocket size, contains more than three thousand black-and-white drawings of the ferns and flowering plants found in Switzerland and the adjacent areas of France and Germany. The drawings are carefully executed and reproduced; but their small size and the fact that they are rather crowded, with some dovetailing, makes it rather difficult to recognize all the species, even though detailed drawings of characteristic portions of flowers and fruits are given. The author himself considers that his drawings are best used in conjunction with one or other of the existing non-illustrated Floras of Switzerland. The fact that the present issue of the Pocket Atlas is a second and enlarged edition is proof that it has served a good purpose.

Below each row of drawings the author gives the Latin, German and French names of the plants, and he indicates by a small initial letter the colour of the flowers. In addition there are twenty-two pages in which some systematic, geographical or general information concerning many of the plants is given. The author generally informs his readers, when that is the case, that the plant to which he refers is not a native of Switzerland, but has become naturalized either by spreading by natural means from adjacent areas or by human agency. This latter will have been the case with such trees as *Catalpa* and *Paulownia*. It is a pity that in some instances no such information is given. Some readers may therefore not know that *Sarracenia purpurea*, which is figured, is a native of wet bogs in North America. It is not a Swiss plant, but may be found at least in one locality about 1,000 ft. above the Lake of Geneva, where it was planted many years ago and has since flourished. The author might also have mentioned the interesting fact that it is an insectivorous plant. But he has been rather chary about letting readers know that other plants like *Drosera*, *Pinguicula* and *Utricularia* are insectivorous. It is a pity that interesting information of this nature or of ecological facts is not given in the notes. It would be useful to reconsider this matter if a third edition is contemplated.

F. E. Weiss

SCIENCE AND AN EXPANDING AGRICULTURE*

By Sir WILLIAM SLATER, K.B.E.
Secretary of the Agricultural Research Council

WHEN the growth of a people has overtaken the supply of food and raw materials from the available land, they have either sought new land to exploit or by better farming produced more from that which they already had. This pattern of expanding agriculture has been continuously repeated throughout the history of civilization.

In England the earliest village communities based on the Saxon manor were self-supporting, the transport of heavy goods from one part of the country to another being almost impossible. As travel became more common in the fourteenth century, the wealthier people began to want luxuries from the Continent. To buy these goods, wool and woollen textiles produced from sheep grazing the English downlands were sent in exchange. So specialized farming began, and the system of exchanging the products of one type of farming for those of another was introduced. This trade greatly strengthened and enriched the life of the static farming communities.

By the seventeenth century the then known methods of expanding the production of food and raw materials were no longer sufficient to meet the demand, and science for the first time came to the aid of agriculture, by showing how more waste land could be brought into use and how the output of the existing farms could be further increased. The application by farmers of the knowledge which was being made available during this and the following centuries was slow, perhaps not surprisingly at a time when the old well-tried methods served to produce enough to give the farmer a satisfactory living. But whereas farming was prosperous, the production of food in Great Britain was not keeping pace with the needs of the now rapidly growing population in the industrial towns. So once more the common pattern adopted by a community in search of food was repeated. There seemed no immediate possibility of an increased yield from the acres of existing farm land, so attention was turned to finding new undeveloped land. Transport, already greatly improved and soon to be revolutionized by the steam engine, had made accessible the vast empty lands of the Americas, and of the southern hemisphere. It was to these lands the people of Britain turned for their food. First they began to grow wheat on the rich virgin soils, then to send their livestock to graze the native pasture.

The system of production used, which might be called static nomadism, had a number of characteristics worthy of note. First, no attempt was made to apply science in the utilization of the new lands, partly because the pioneers did not know what questions to ask; partly because the man of science could not have answered the questions which should have been asked without extensive research. Secondly, the food produced was cheap, being subsidized by continuous drawings on the capital reserves stored in the virgin lands and by the use of native labour. Cheap food, combined with intensive industrial specialization, resulted in cheap manufactured goods, which could be advantageously exchanged with other countries. Thirdly, this extremely advantageous economic system was entirely dependent on keeping transport moving freely; if it were interrupted the den population must starve. Fourthly, the nation livin in this way had to be powerful enough to preven others encroaching on its food-supplying areas.

The United Kingdom exploited this way of livin successfully for a hundred years; in the end to successfully. So great became the quantity of chea food that it almost ruined our own farmers, whi the capital assets in the virgin soils on which it dre were being rapidly exhausted.

When war partly blocked our transport lines du ing 1914–18, British agriculture had to try to f the wide gap between our needs and our supplie The farmers, who had changed their methods litt in the past fifty years, set about their task not b trying to increase yields but primarily by bringin back into cultivation land which had been allowe to fall down to indifferent grass during the years depression. For a short time farming was prosperou but once ships began to move freely again the pressu of cheap food from overseas was too great to resi and the products of British farms were no longe wanted.

Science could claim little part in the food pro duction campaign of 1914–18, but the study of agr cultural science was greatly stimulated by the fir danger of famine Great Britain had known for mor than seventy years.

Before the First World War, a number of far sighted men had pointed out that British agricultur if it were to survive, must adopt new methods base on scientific knowledge, and that these could onl be worked out in the laboratory and on the exper mental farm. In 1909, research for the advancemen of agriculture received its first direct State-ai through the Development Commission, and plan were laid for the expansion of the work at Rotham sted, Long Ashton, the universities and the agr cultural colleges, and for the establishment of number of new institutes. Under the stimulu created by the War, rapid progress was made, lab oratories were built and equipped and young me recruited. Within a few years, however, depressio hit not only agriculture but the whole country. Th research institutes carried on with their work, bu growth was halted and recruiting almost ceased fo fifteen years. We are constantly reminded to-day o these blank years by the dearth of men in agricultur research between the ages of forty and fifty-five.

When a Second World War again disrupted ou transport lines, this time more effectively than i 1917 and 1918, the farmers, with the help of th scientific workers, led a revolution in food productio Once more there was a great ploughing up of gras land, but it was accompanied this time by increase in the yield per acre and per beast. The joint effort of farmers and men of science showed clearly tha Britain need no longer depend on the continuou exploitation of virgin lands to meet our needs. W can produce on our farms at home, and in othe lands settled by our own people, the food we want but to do this we must develop research to the fu and apply the findings vigorously in practice.

The value of research was recognized, and betwee 1944 and 1946 the late Sir John Fryer, the the secretary of the Agricultural Research Council, pre ared a plan for the development of research which was expected to be completed in ten years. This ncluded the enlargement of existing institutes and he establishment of new ones in subjects for which facilities were not already provided. The plan has rogressed, not altogether at the scheduled pace, but teadily and without serious omissions. Delays have not been due to lack of money, but to the shortage f trained men and the lack of buildings. We have earnt again that research cannot proceed in jerks, attempting to make up in a few years the neglect of many. If research is to be successfully developed, there must be a steady recruitment of scientific staff. Since it becomes known that men are no longer wanted for any particular type of work, entrants to the universities avoid training leading to it, and when recruitment begins again there are few applicants with suitable training. The flow of entrants to the universities starts afresh with the knowledge of vailable openings, but it is five or six years before hese students are ready to take the most junior esearch posts. Now that the men who entered the universities after the War are available, the supply of man-power has improved and the chief difficulty ests in getting building work completed. There is, however, on every side goodwill towards the agricultural research service and great enthusiasm among he workers. With these assets the difficulties nherent in our present economic troubles can be overcome.

---

* Substance of an Evening Discourse delivered at the Belfast meeting of the British Association on September 8.

The need for the vigorous application of the results of research in farming has also been recognized by the setting up of a chain of experimental husbandry farms and horticultural stations, to apply the findings of the research institutes under different conditions of soil and climate, to carry out experiments affected by local conditions and to take the place occupied by the pilot plant in the chemical industry.

This general acceptance of the value of research work and the importance of the application of its results in agricultural practice is part of a great change in our national outlook, in that it is now generally accepted that our hope of survival as a nation depends on greater output from our farms. Not unnaturally, the bulk of the nation, who are neither farmers nor men of science, wish to know what is involved before they commit themselves to a programme designed to give a high output on existing farm-land and to render fertile and bring into full use land of low productivity. They may recognize that it is the only alternative to starvation, but still they rightly wish to know what is the cost.

Sir John Russell made a brilliant summary of the means by which food production can be raised in his presidential address to the British Association at its Newcastle meeting. Anyone hearing or reading that address must be convinced of our technical ability to achieve an enormous increase in food production. Sir John, however, added this warning : "If more food is needed, more work must be done to earn it". It is clear from the context that Sir John was referring not only to work on the land ; he was also speaking of the work involved in producing the equipment and supplies needed for an expanding agriculture.

There is a true parallel between the great war-time projects and a major drive for increased food production. It may be suggested that in war there is the consciousness of immediate danger not present in time of peace acting as a spur to common effort and sacrifice ; but famine, although it may be a less tangible enemy than an advancing army, is even more deadly and more ruthless. Again, it may be argued that war-time projects, often great in conception and large in scale, fire the imagination so that the most humble duty gains an added sense of importance and urgency, whereas agriculture, lacking these qualities, reduces all effort to the common daily round of work. This may have been partly true in times when farming methods were static, when tradition ruled over everything ; it is certainly untrue of an expanding agriculture and of the scientific work which makes the expansion possible.

If we look at the work which is already being done and that which is projected in the British Isles and elsewhere throughout the Commonwealth, we find projects as large and as daring as anything attempted in war. Here are some examples.

The first is a story of land infertile due to lack of water turned into rich farm-lands by the irrigation engineers, and of their titanic scheme to change the course of a river and send part of its waters to double the irrigated area. The Great Dividing Range of mountains follows closely the east coast of the Australian continent, until reaching the extreme south it turns at right-angles to run due west. In the south-east, roughly where the range makes its sharp turn, the land rises to its greatest height in the Snowy Mountains of more than 7,000 ft. Here there is an area of 40 square miles with an altitude of more than 6,000 ft. and an annual rainfall at the highest points of more than 100 inches. From these snow-covered mountains rise the Murray River and its great tributary, the Murrumbidgee, to flow westwards through New South Wales and Victoria, behind and parallel to that part of the Great Divide that runs westward from the Snowy Mountain area. The moist winds from the sea leave most of their water on the slopes of the Great Divide, so that the country through which the Murray and the Murrumbidgee flow, on the landward side of the mountains, has a low rainfall of from 20 inches near the mountains to 10 inches farther inland. The soils of the river valleys are alluvial ; much of the area is covered with good red-brown earths and other fertile soils, but without water they are of little agricultural value. Engineers, by building dams and cutting canals, have carried the water from the river to irrigate each year an area of more than a million acres—about twice the area of the county of Derry—of fertile land. From sparse grazing it is now producing milk, butter, beef, pork, fat lambs, fruit of all kinds, and rice. More dams and canals are under construction, which will irrigate further areas of equal size, making a total of land irrigated each year of more than two million acres. In addition, water for domestic purposes and stock is supplied to a much larger area. These extensions will have absorbed all the available water from these great rivers. No definite estimate has been made of the increased production which will follow the completion of this great network of irrigation, but on the basis of the output figures available for the present irrigation areas in Victoria, where 680,000 acres have yielded £15,000,000 worth of produce, it should be of the order of £40,000,000.

This is a large and ambitious scheme, and the Federal and State Governments might well have been content to rest on their laurels ; but there will still be much good land left unwatered when every available acre/ft. of water has been taken from the Murray and the Murrumbidgee, so the engineers have considered another plan.

Rising in the same area as the Murray and the Murrumbidgee is the Snowy River; but it flows not west into the dry plain, but south through well-watered country to the sea. To the Australian, who is, over a large part of the continent, always fighting drought, this appeared grossly wasteful. If, he argued, this water flowed west into the Murray valley instead of south into the sea, then at least another million acres could be intensively irrigated. But a mountain range lay between the head waters of the Snowy River and those of the Murray and Murrumbidgee, so this seemed no more than an idle dream of what might have been, until the engineers and geologists got together and produced a scheme—now accepted by the Federal and State Governments—by which a large part of the waters of the Snowy River will be taken through two great tunnel systems under the mountain peaks and discharged on the western side into the Murray and the Murrumbidgee. The tunnel to the head waters of the Murrumbidgee will be 15 miles long, with a sectional area of 900 sq. ft. (the Simplon tunnel is 12·3 miles long), that to the Murray is to be in three sections, the first 8 miles long, with a sectional area of 700 sq. ft., the second 9½ miles long, with a sectional area of 1,150 sq. ft., and the third 4½ miles with a sectional area of 1,500 sq. ft. The cross-section of the tunnel is increased as it picks up water from other tributaries through vertical shafts. In addition to these main tunnels the scheme involves many subsidiary tunnels, seven great dams with storage capacity of more than 3,000,000 acre/ft. and more than 400 miles of race lines. Apart from its agricultural importance in making possible increased production of the order of £20,000,000 a year, the scheme provides for the generation by water-power of 2½ million kilowatts of electric power.

This surely is a project to fire the imagination and to call forth a great co-ordinated effort; it is as exciting as the original exploration of the Australian continent and calls for courage equal to that shown by the early explorers.

This, it is true, is only one scheme, large in scale and dramatic in its daring conception, but it illustrates well what the engineer is now doing in many parts of the world, and can do increasingly in the future, to bring water to arid but otherwise fertile land. The cost of irrigation may be high, but so also is the return.

There are deserts which do not lack water, but where the land is barren, due to the absence of one or more of the elements essential for plant or animal growth; the amount of the missing element required is often very small and large areas of land can be made fertile at relatively low cost.

In parts of Scotland and the south-western counties of England a nutritional disease of sheep has been recognized for more than a century. The name 'pine' describes the disease well; the young lambs gradually waste away and die. The only remedies known were to move the lambs to unaffected pasture or to bring soil from other districts and give it, mixed with water, as a drench. The same symptoms were observed in other parts of the world, particularly in Australia and New Zealand. It was thought the disease might be a form of anæmia, and ferrous sulphate was tried as a remedy with varying results. After further experiments, it was shown by Marston that the so-called 'coast disease' of the South Australian littoral, and by Underwood and Filmer that enzootic marasmus in Western Australia, responded dramatically to small doses of cobalt given by mouth. Animals could be kept healthy on the deficient pasture, and those already seriously affected responded rapidly on receiving doses of one milligram of cobalt a day. Other workers soon established tha cobalt deficiency was responsible for pine in th Cheviots and many other parts of Scotland, while i England the same condition was proved to exist in Devon, Cornwall and Worcestershire. Bush sickness, which occurs on large stretches of the pumic soils of New Zealand, was also shown to be due to lack of cobalt. Salt sickness in Florida and nakuruit in Kenya were later added to the list of disease responding to treatment with cobalt. Marston, who has made an extensive study of this subject, ha recently stated that there are probably many othe parts of the world where animals are seriously affected by lack of cobalt and where its administration would produce the same striking results. Cobalt is not the only element having remarkable effects when applied to deficient soils in small quantities or when fed to stock grazing deficient herbage. Low concentration of copper, molybdenum, boron, manganese, magnesium, zinc and sulphur have all been proved to be responsible for failures either in crops or in stock Frequently the trouble arises from the lack of two of these elements, or from the excess or lack of one rendering another unavailable. All areas where the yields of crops and stock fall below those normally to be expected from the soil and climate must be regarded as probably deficient in some nutrient and examined in the hope that the cause of the lack of fertility can be found and set right.

There is often a complex relationship between soil plant and stock which makes the problem difficult of solution. The area of South Australia in which 'coast disease' occurs consists of two soil types, the one composed of calcareous marine shell fragments, the other of siliceous sands. Sheep grazing on both these soil types responded to treatment with 1 mgm. of cobalt a day, but another syndrome then appeared which had been previously masked by the more immediate effects of the cobalt deficiency. This proved to be due to a lack of copper. When both cobalt and copper were administered the sheep grew satisfactorily and remained healthy.

The next problem was to get a sufficient growth of pasture and other crops to feed larger numbers of sheep. Applications of the normal fertilizer mixtures of phosphate, potash and nitrogen failed to produce good yields of cereals or to establish pastures of sown grasses and legumes. It was then found that on the calcareous soils the lack of growth of plants was also limited by the copper deficiency and that a dressing of 7 lb. an acre of copper sulphate enabled cereals, legumes and grasses to respond fully to dressings of the major plant nutrients.

The addition of copper to the siliceous sands did not, however, produce the same results, and it was only after further years of experiment that Marston completed his great work by showing the lack of plant growth on these soils was due to a deficiency of zinc. To drive through the untreated areas and then to come quite suddenly on the improved pasture is to know what the prophet meant when he spoke of the desert being made to "rejoice and blossom as the rose". Nothing could be more rewarding and exciting than the work of the farmers and scientific workers in converting these wastes into fertile lands. The total effect on food production cannot as yet be estimated; all we know is that it must be very arge, as the hundreds of square miles involved are uitably treated and divided into farms supplied with the necessary buildings and fences.

The samples so far given have been of bringing fertile land into use; but an equal, or possibly reater, contribution to our food supplies can be ade by increasing production on existing farm ands. There are two ways of doing this: one by creasing yields, the other by preventing waste. It as often been pointed out that the average yields of rops in the United Kingdom are much below what e best farmers expect as their normal return. There as been since the beginning of the War a steady crease in the average yields of our crops; that of heat, for example, has risen by approximately 0 per cent. This may seem in itself satisfactory, but appears less so when the present average figures f about 20 cwt. per acre are compared with the 0 cwt. on light land and 40 cwt. on strong land btained by many good farmers. The difference here so lies in the full application of scientific knowledge. igh yields depend on the use of a variety bred and lected to suit the conditions of soil and climate, the plication at the right time and in the right way the amounts of the different fertilizers which have een shown by the soil chemists to give optimum ields, the proper cultivation of the soil and the fective control of pests and diseases.

These sound practices are, however, not fully fective if the soil is not at the same time kept at a igh level of fertility. In the United Kingdom we ave never entirely forgotten the teaching of our reat farmers on the need for a sound rotation, including crops to be eaten by stock in the field; but e have found their precepts difficult to follow in e years of depression and of rising working costs. he hurdled flock and the bullock yard on which rtility was based have largely disappeared, and the able land has been used to an increasing extent r cash crops. Increased use of fertilizers and nproved methods of controlling weeds and diseases ave counteracted the loss of yield that would have evitably followed the resultant lowering of fertility.

In the years immediately before the War the gronomists, led by Stapledon, took up the old idea the ley and developed it as a means of maintaining utput under modern conditions, while at the same me building up the fertility of the soil. The replacement of permanent grass by well-grazed short-term ys of three to four years, covering every field on e farm in turn as part of the normal rotation, or here there was no permanent grass the introduction a similar ley to replace the root break and the ne-year ley in the old four-course rotation, is now ell understood and generally accepted.

We do not know yet how great a revolution this odern system of ley farming has brought about; e expected an improvement due to the re-introuction of stock on the arable land, but the men of ience themselves have been surprised at the results hieved and are now busily at work seeking the planation of the unexpected success, in order to fine the conditions under which the ley produces e maximum benefit.

It is known already that the more productive the y and the heavier the stocking, the better the arable ops that follow; we know, too, that a ley should ways be broken while it is highly productive and at the arable land should be re-sown to a ley while fertility is still high. In this way the fertility of e land can be steadily raised and year by year the crop yields increased. We cannot say what the maximum yields will be; the time may come when a yield of two tons of wheat an acre may be regarded as the normal.

Our immediate tasks are to learn all we can about the beneficial effects of the ley on soil structure, and to get the knowledge of how to build up fertility and increase yields of crops widely known and used on British farms.

Ley farming must also find an increasing place throughout world agriculture. Land that has been continuously cropped must be rested under a sward grazed by animals, and the native pastures that carry few animals must be fertilized and sown to new grasses and legumes, if they are to make their full contribution to the world's larder. Each set of environmental conditions into which these methods are to be introduced needs careful scientific examination.

If we grow heavier crops we must protect them from pests and diseases. The loss of food due to the attacks of wild animals, insects and plant diseases is, we know, enormous. In a recently published book, "Untaken Harvest", George Ordish has summarized the existing information about crop losses. He reaches the conclusion for Great Britain that in the year 1947, after spending £10,000,000 on the control of insect pests and diseases, the losses from these sources were equivalent to £78,000,000, and expresses this graphically by saying that it is equivalent to 33,000 of our farms producing no crop, and 51,000 skilled farm workers achieving nothing with their labour. To this must be added the estimates for the damage caused by rabbits and rats. Rabbit damage in Great Britain has been estimated at £50,000,000 per annum, and that by rats at £40,000,000.

All these figures are estimates and the damage must vary from year to year, but it would be safe to assume the total damage to average more than £100,000,000 per annum. The chemists, entomologists and plant physiologists are waging a continuous war against these enemies and have won some remarkable successes since 1947, but there is still much to be done. It seems idle to begin to speak of food shortage while we are losing more than 5,000,000 tons of food each year, and not putting into the battle the effort we should have made to save so large an amount in war-time.

The proportional losses in other countries are as high. Ordish calculates that the losses in South Africa are equivalent to half a million acres, and the loss through fungus attacks on cereals in Australia as equal to the yield of more than 900,000 acres. The same picture can be found in every country, varying in type and extent, but everywhere representing a very considerable fraction, often as high as one-fifth of the potential output.

What has been said of increases in crop production and losses due to pests and diseases can be repeated for the animals on the farm. The output of milk, meat and eggs depends on good stock, the right management, and the control of disease. Figures given for possible improvement in the conversion of crops and grass into animal products are little more than inspired guesses. They all agree, however, in assessing the figures as very high. It would be conservative to estimate a 20 per cent increase in the output of animal products from the same amount of feeding stuffs if the level of production on all the farms in Great Britain could be raised to the level, not of the best, but of the good, by the application of existing scientific knowledge. In few countries would the increase be less and in many countries it would be much higher.

These examples of what could be done to expand agricultural output by the application of science serve to show that the world's food production is far below the maximum.

The rapidly increasing human population presses hard on the heels of available food supplies, and if production remains static, famine is inevitable. The control of population will come with the spread of education, but it will be a slow process; in the meantime the number of people to be fed will continue to rise rapidly. We have in the expansion of production the only means to ward off this danger which threatens the whole world, and particularly dense centres of population such as the United Kingdom.

Increased food production will require great efforts, and for a time sacrifices. Now more than at any other time in the world's history is that increase needed. Have we as a nation, has the world as a whole, the faith and the courage to set aside from our available supplies of trained men and materials those needed for the scientific expansion of agriculture? On the answer to this question may rest the fate of mankind.

X-RAY SHADOW MICROSCOPY

By DR. V. E. COSSLETT and DR. W. C. NIXON

Cavendish Laboratory, Cambridge

THE simplest way of making an enlarged picture of an object is to put it close to a point source of illumination and to receive its shadow image on a photographic emulsion at a distance. The magnification obtainable is limited only by practical considerations. The resolution is determined in the first place by the size of the source, and secondarily by Fresnel diffraction in the object and by the grain size of the emulsion. When X-rays are used as illumination, their short wave-length permits higher resolution than with visible light and penetration of objects optically opaque; differential absorption may also enable specific elements to be detected. Shadowgraphy with a point source of X-rays was first proposed by Sievert[1]; later von Ardenne[2] suggested using electron lenses to reduce the electron beam to the required minute spot, but he does not appear to have made any experimental investigations. Recent work has yielded enough evidence to judge the potential value of the method and the limits of its performance.

Microradiography with this method offers higher ultimate resolution than does the contact method, in which the object is placed against an emulsion at some distance from a source of normal size; the resolution is then limited primarily by the grain size of the emulsion and finally by the wave-length of light used in subsequent enlargement. A value of 1 μ has been obtained by Engstrom[3] using Lippmann emulsions, and Ehrenberg and Spear[4] claim rather better results. The shadow projection method, by contrast, is limited in resolution only by the size of electron spot which can be obtained, in the order of 100 A. The shadow method also has the advantage in resolution, and in simplicity, compared with the use of reflecting surfaces to make a true X-ra microscope[5,6], which theoretically can also exceed th optical limit but seems to be restricted by practic difficulties to some 2000 A.[7,8].

The attractions of the shadow method have be obscured by fears that a sufficiently small focal sp could not be obtained or that the available X-r output from it would be so weak that exposure tim would be impracticably long[9,10]. For this reas Marton[11] recently suggested using pulsed co emission from a tungsten cathode. However, expe ments over some years have shown that this limit tion, although real, is not such as to prevent optic resolution being at least equalled; prelimina results of the shadow method were lately publish showing a resolution of a few microns[12]. Attenti to experimental details, and especially to the desi of the magnetic lens used for producing the micr source, has allowed the performance to be broug closer to that of optical techniques. A full accou of the apparatus is in preparation, and a discussi of its application to the study of insect morpholo will shortly appear elsewhere[13]. Here the gene scope of the method and its future possibilities a limitations will be sketched.

The essential need in realizing the shadow princi is to make the utmost use of the X-rays generated the target. This is achieved by using a tungsten f as target, on one side of which is incident the electr beam, while the specimen is placed almost in conta with the far side, with the advantage that it is a in air. By using magnetic electron lenses a po focus less than 1 μ in diameter can be obtained, a the X-ray source will be of similar size if the f itself is not thicker than this; 1-μ tungsten foil h been mostly used, but experiments have been ma also with laminated foils.

The resulting resolution in the shadow image determined by the size of source, so long as the effe of Fresnel diffraction is rendered negligible bringing the object very close to the source. T recording emulsion is placed as near as possible, the interest of short exposure, but must be f enough away for the inherent image detail to larger than the grain size; the camera has usual been a few cm. long. With an object-target distan of less than 1 mm. an initial magnification approac ing 100 × is not difficult to obtain. Fig. 1 shows test micrograph of a silver grid of 1,500 meshes the inch, having bars approximately 2 μ and 3 μ wid

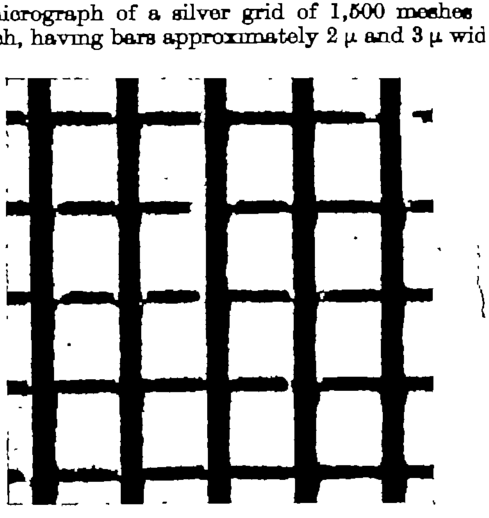

Fig. 1. Silver grid of 1,500 meshes per inch with bars 2 μ and 3 μ wide Initial magnification × 100; total magnification × 70

ne imperfections are rather less clear than in the est obtainable optical picture, and the resolution is timated at about 0·5 μ.

The technique can be applied to any material ntaining inhomogeneities which cause differential bsorption of X-rays, the wave-length being adjusted give maximum contrast in combination with dequate penetration. For biological material, which as so far been the main subject, a long wave-length required and a voltage of 10 kV. was chosen for reliminary studies ; the minimum wave-length is hen 1·2 A. with a peak intensity at about 2·5 A. uch a slow electron beam is readily focused by agnetic lenses, and a focal length of 1 mm. can be btained with an excitation that does not call for ooling of the windings (2,000 amp. turns). A focal pot smaller than 1 μ can thus be obtained by imaging tungsten filament with a single lens ; a condenser ns has been added to control the illumination onveniently.

A typical micrograph obtained in these conditions s shown in Fig. 2, the fruit fly *Drosophila melanoaster*. By bringing the specimen closer to the target higher primary magnification may be obtained at he cost of a reduced field of view ; Fig. 3 shows an solated head of the same insect. In each case the xposure time was 5 min. ; a piece of 1,500 mesh rid serves as magnification and resolution standard. he specimens have been freeze-dried, since the high water content of the living insect obscures detail in he shadowgraph ; some degree of drying is necessary or high resolution and contrast, and freeze-drying as proved to give least distortion of internal tructure. Some work has been done on intermittent bservation of living insects, immobilized for the eriod of exposure by anaesthesia. The poor resolution btained may in some cases be more than comensated by the possibility of following internal rocesses, such as egg formation, in organisms paque to light. The changes induced by high X-ray losage may also be of interest ; rough preliminary neasurements show that the total dose received luring photographic exposure is of the order of 100 r.

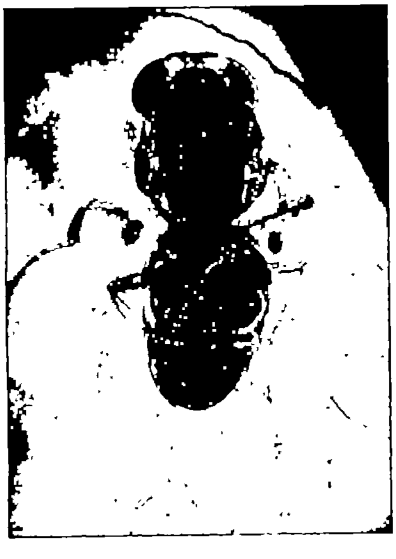

Fig. 2. *Drosophila melanogaster*, freeze-dried, with 1,500 mesh reference grid. Initial magnification × 20; total magnification × 30

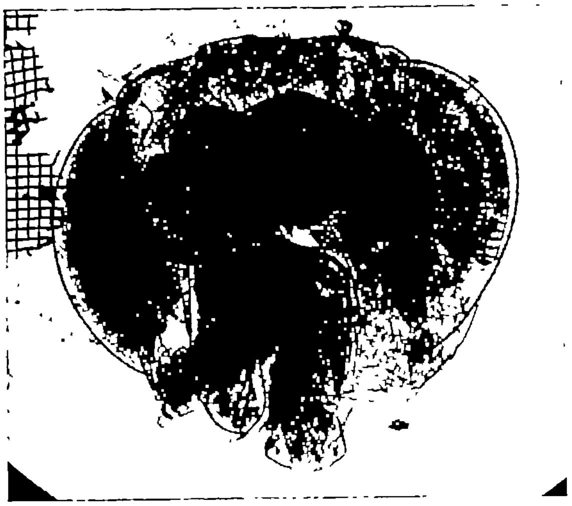

Fig. 3. Head of *Drosophila melanogaster*, freeze-dried, with 1,500 mesh reference grid. Initial magnification × 30 ; total magnification × 90

In its present form, with a resolution somewhat short of that of the optical microscope, the chief value of the method lies in the possibility of examining specimens normally opaque to light. It is also an advantage that stereographs can be obtained of equally high resolution, since the whole depth of specimen is in focus compared with the restricted focal depth of an optical microscope at high resolution. A stereo-view of a head of *Drosophila*, for example, shows the complex structure of the eye and brain in immediate three-dimensional perspective. The prospect appears of examining at high resolution much thicker sections of bulk tissue than can be tolerated in normal microscopy.

The main difficulty in the way of further development threatens to be that of electron intensity. It has long been known that the dissipation of energy from a focal spot becomes relatively more rapid as its diameter is reduced, and conditions are specially favourable in a laminar target where heat flow is almost entirely radial. Detailed investigation[14] shows that with a spot of the order of 1 μ, the temperature can be raised towards the melting point only by over-running the filament considerably compared with normal operating conditions. The limitation on exposure time with still smaller spots then resides in the filament rather than the target. An exposure time between 1 and 10 minutes has been found practicable with a spot of less than 1 μ, without seriously shortening the life of the filament.

The decreased X-ray output resulting from a further reduction in spot size to 0·1 μ could be partly offset by reduction in camera length and by further overrunning the filament, so that the exposure time need not be greatly increased. But the use of an electron spot of the order of 100 A., which can be obtained by two stages of demagnification of the beam, would seem to demand exposure times of the order of one hour. In any event, it is doubtful if many biological problems exist for which such a resolution would be useful, owing to the poor absorption of organic matter for X-rays ; features 100 A. thick would only give sufficient contrast to be observed if very long wave-lengths were used, requiring a vacuum camera. However, loading of the specimen with heavy elements may be practicable, and there are problems of a metallurgical and inorganic nature for which such a high resolution would be useful. Where the absorption of X-rays is much greater, a higher electron voltage could be used, with corresponding improvement in the efficiency of X-ray production. For the present, attention is being paid to refining the existing apparatus and exploring the range of its application.

NEW EVIDENCE OF COMMUNICATION IN THE HONEYBEE COLONY*

By C. R. RIBBANDS
Bee Department, Rothamsted Experimental Station

Dr. H. KALMUS
Galton Laboratory, University College, London

AND

H. L. NIXON
Plant Pathology Department, Rothamsted Experimental Station

SCIENTIFIC interest in honeybees centres upon their most striking achievement—the organization of a social life. Social co-operation and coherence presuppose communication between the members. Part of the 'language' of bees has been studied and described by K. von Frisch[4-6], but his investigations were only concerned with recruitment to crops by successful foragers. There must also be other types of communication, concerned with co-ordinating the various activities within the colony, and there might be means by which members of a colony recognize each other.

G. A. Rösch[7] showed that marked workers in an observation hive undertook a sequence of tasks according to their age—brood-rearing, nectar ripening and storage, wax production and comb-building, and finally foraging. However, there is evidence that this succession need not apply in colonies with bees of abnormal age distribution[8,9].

Ribbands[1], who marked groups of workers which had all emerged into a colony on the same day, found that when they commenced their last task—foraging—their ages lay in the range 9–35 days. In addition, the expectation of foraging life of the last group of bees to commence this activity was substantially less than that of their comrades (Fig. 1), so that senility had played some part in their mortalities and they had commenced foraging at a more advanced 'physiological age'. In order to reduce the effects of changing weather conditions, means for three days running were applied to the data concerning the age at which the bees commenced foraging; but despite the smoothing effect of this procedure, the distribution was markedly trimodal (Fig. 2); the peaks indicate that, even in this normal colony, most of the bees had skipped some of the duties in the sequence.

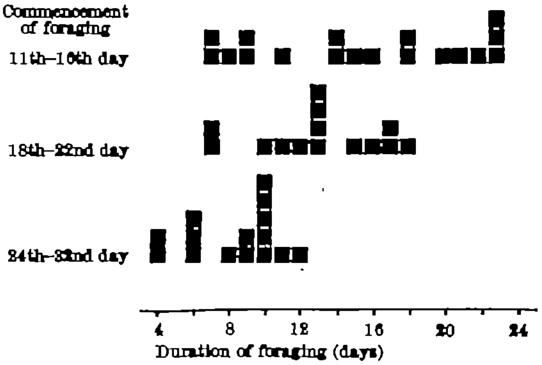

Fig. 1. Duration of foraging for individuals, exp. 1

Thus Ribbands concluded that the age of the individuals was not the over-riding factor in determining the allocation of their duties, but that some other factor was more important. The main tasks o a colony are related to the food supply, which may determine the proportion of bees required for each task. It was thought possible that food supply also affected the metabolism of the individual workers and so led to an appropriate redistribution of their labour to the required proportions; evidence to support this hypothesis is detailed in the full paper[1].

It was supposed that, if food supply determined the allocation of duties, any change in the supply would be quickly appreciated throughout the colony. Investigating this possibility, Nixon and Ribbands showed that there exists a rapid and extensive sharing of food between the members of a colony. In one experiment six foragers from a colony of 24,500 bees were marked and trained to a dish containing sugar syrup. This dish was then replaced by another one which was filled with 20 ml. sugar syrup which contained 100 μC. of phosphorus-32, and in 3¼ hours the six marked foragers carried this solution into their colony. Two hours later, 70 foragers were collected from the hive entrance and 6–12 honey bees from each of the 33 combs in the hive. 62 per cent of these foragers and 19 per cent of the bees from the combs were radioactive. Twenty-four hours later, larger samples were taken; 76 per cent of the foragers and half of the bees on the combs were radioactive. The wings and legs of these bees were

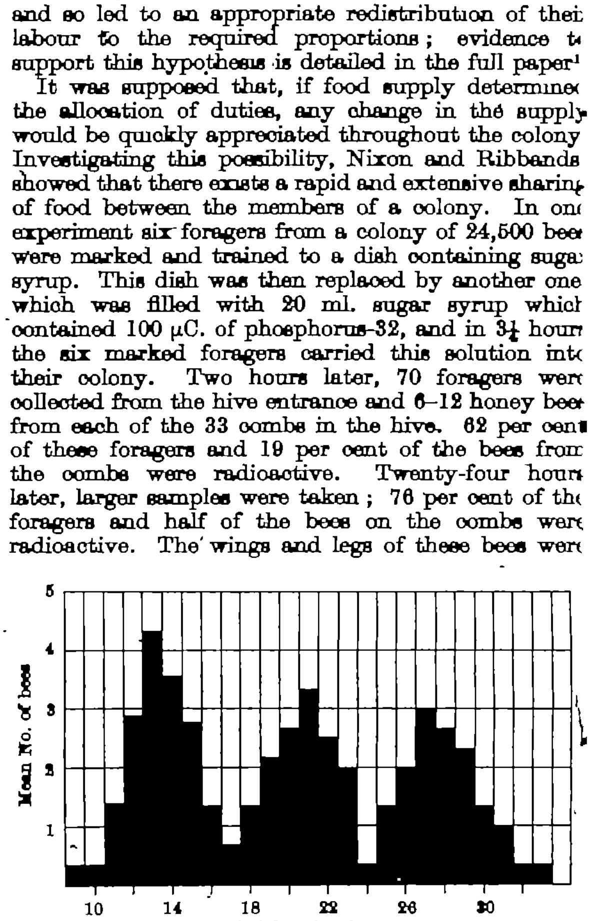

Fig. 2. Age at which foraging commenced, exp. 1. Three-day running means

ot radioactive, so that the transmission had not een caused by external contact, but by food intake. n addition, forty-eight hours after feeding the tracer rup, 100 per cent of a sample of 85 of the older rvæ of the colony were radioactive.

---

* Summary of three papers (refs. 1–3) read before the Royal Society on June 19.

This food sharing could provide a material basis for e known division of labour in the honeybee colony. ibbands[1] supposes that at any particular time each sk in the colony is undertaken by a group of bees hich differ slightly in age; the main tasks involve ood manipulation, and any surplus is appreciated by ll members as a consequence of the widespread food ransmission; the oldest bees of the group are then ost likely to leave this activity and turn to which- ver of the subsequent duties is most in need of ecruits.

The results of the food-transmission experiments re complementary to the unexpected results of xperiments concerning the odours by which honey- ees recognize their companions[9]. Von Frisch and Rösch[10], who trained two colonies of honeybees to isit neighbouring dishes of syrup and noted that ewcomers were preferentially attracted towards oragers from their own colony, thought that this reference was caused by a difference in odour. For re-investigation of this problem, Kalmus and ibbands[3] designed the following technique. Two etri dishes, *a* and *b*, were placed about a yard apart bout a hundred yards away from a pair of colonies and *B*. A wooden screen was placed between the etri dishes in order to facilitate the separation of dours emitted in their vicinity. One evening the ntrance of colony *B* was closed, and the next orning dish *a* was filled with sugar syrup and a roup of 50 foragers from colony *A* were trained to . The thoraces of these bees were marked with hite paint and any additional bees were killed. hat evening the entrance of colony *B* was opened nd that of colony *A* closed. Next day dish *a* remained mpty, dish *b* was filled with sugar syrup, and 50 oragers from colony *B* were trained to dish *b*. The horaces of these bees were marked with blue paint, nd additional bees were again killed. The entrance f colony *A* was now opened, and dilute syrup was pplied at both dishes. Soon the marked bees from oth colonies were foraging at their respective dishes. oncentrated syrup was then supplied at both dishes n order to encourage the recruitment of newcomers[11], hich were marked on their abdomens with paint of he same colour as that on the thoraces of the bees rained to the dish which they were visiting. When ufficient recruits had been marked, the dishes were emoved. That evening both hives were opened and ll marked bees found were killed and recorded.

In experiments with different pairs of colonies, it as always found that 70 per cent or more of the ecruits went to the dish being visited by guides from heir own colony. These highly significant preferences onfirmed the result of v. Frisch and Rösch.

Another experiment involved only one colony, rom which a group of 50 bees were trained to one f the two dishes, and marked. New dishes, con- aining concentrated syrup, were then placed at both ites, and all recruits to either dish were killed and ecorded. During the first two hours of observation, 5 recruits went to dish *a* visited by the trained bees, ut only 3 went to the other dish, *b*. The dishes were hen exchanged. During the next 15 minutes only ne recruit arrived at dish *b*, which the trained bees ere now visiting, but seven recruits went to dish *a*. hus the recruits had not been attracted to their trained comrades, but to something pertaining to the dish which had been visited by them. This could only be an odour, presumably emitted from their abdominal scent gland[12]. Other observations indicated that this odour persisted for at least two hours.

Further experiments, using halves of recently split colonies and testing by the basic technique, showed that the distinctive odours could develop quickly and were thus not inherited. Then on September 20, 1951, when little natural forage was available, a colony was dequeened and divided into three nuclei, *D*, *E* and *F*, which were set out in a row ten yards apart. *F* was then fed with half a pound of heather honey and one tablespoonful of treacle, while *D* and *E* were not fed. Foragers were then trained and marked, and on September 29 *D* and *F* were compared. 43 correctly marked and 14 incorrectly marked recruits were found in *F*, and 11 correct and 6 incorrect ones in *D*; thus a highly significant difference ($P = 0{\cdot}006$) had developed between the foragers of these nuclei. On October 5 the two unfed nuclei, *D* and *E*, were compared. 22 correctly and 20 incorrectly marked newcomers were found in *D*, and 16 correct and 13 incorrect ones in *E*; this difference is not significant ($P = 0{\cdot}7$). On October 6 *E* and *F* were compared. In *F* there were 37 correct and 16 incorrect recruits, and in *E* there were 35 correct and 5 incorrect ones. This difference in visiting is highly significant ($P < 0{\cdot}001$). Thus it appeared that no significant difference had arisen between the two unfed nuclei, whereas the fed nucleus had developed a distinctive difference in relation to the other two as a consequence of the differential feeding.

Differences in olfactory attraction do not require absolute differences between the odours emitted; they could also arise from relative differences in the proportions of the same constituents. Thus one would expect that odours from bees of one colony would attract bees from other colonies but to a lesser degree, as the experiments demonstrated. The different mixtures of odours could be derived more or less directly from differences in the crops harvested by the colonies, and a very thorough and extensive food transmission could ensure that the diet of all the foragers of any colony was almost identical, so that at any one time they could all emit similar odorous waste products. Scouts from neighbouring hives may often find different crops, and the readiness with which successful foragers communicate the whereabouts of crops to recruits[13] would maintain this difference so that diets of nearby colonies were not identical; thus the foragers of neighbouring colonies would have different odours.

The foregoing results are relevant to other problems. It has been held[14] that some of the phenomena involved in colony robbing and in queen introduction were explicable in terms of distinctive colony odours; the more recent opinions[15,16] which have rejected this hypothesis may now need revision. An observation of Kalmus[17] concerning fighting between bees of two visibly different strains which were trained to the same dish of syrup can now be explained in terms of distinct colony odours. Food transmission may be an attribute of all social insects, and it would facilitate the rapid dispersal of insecticides[18,19] and drugs.

The results also pose the following new problems, which we are now investigating. Production of the distinctive colony odours suggests that food transmission is even more thorough than has now been recorded, so that a detailed quantitative analysis is desirable. Perception of the distinctive odours suggests that honeybees possess a much more delicate capacity for distinguishing between different mixtures of odours than has been described[20]. It is certain that the most important function of the distinctive odours is facilitation of the social coherence and defence of the community.

NEWS and VIEWS

British Association: President for 1953

THE president-elect of the British Association for 1953, when the annual meeting will be held in Liverpool, is Sir Edward Appleton, principal and vice-chancellor of the University of Edinburgh since 1949. Sir Edward is well known among men of science both as an original investigator of outstanding ability and also as an administrator of scientific research. His fundamental work on the transmission of radio waves, carried out while he was Wheatstone professor of physics in the University of London (King's College) and later Jacksonian professor of natural philosophy in the University of Cambridge, received just acknowledgment by the award of the Nobel Prize for Physics in 1947. Then in 1939 he gave up the direct pursuit of research to become secretary of the Department of Scientific and Industrial Research, a post which he held for ten years— a period which saw the growth on an enormous scale of the participation of the State in fundamental scientific research and development. In all this activity Sir Edward was one of the leading figures, and his wisdom and characteristically gentle but persuasive drive enabled him to exert widespread influence. In 1949 came another change, when he went to the University of Edinburgh as principal and vice-chancellor, thus in a way completing his change-over to interest in administrative activities. Here he has already made his mark in the University, though he contrives to maintain his interest in his own special field of radio research. The British Association is fortunate in having so many-sided a man to guide it during the coming year.

Psychology at Manchester: Prof. T. H. Pear

PROF. T. H. PEAR, who retired from the chair of psychology at Manchester in 1951, is to be succeeded by Dr. John Cohen, lately of Birkbeck College, London. Prof. Pear's tenure of his appointment has been of notable length, for it began in 1919, when a lectureship of which he had been the first occupan was upgraded. He had previously been a student a King's College, London, and at Würzburg an Giessen; and, like that of many pioneers of psychology, his work was originally developed under th wing of philosophy with strong links with both physic and physiology. He has displayed great variety i his interests. From motion-study in coal-getting t the investigation of the expression of personalit through the voice is a great jump, but Pear has bee equal to it. In recent years he has focused his attention mainly on social psychological problems fallin on the verge of social anthropology, and he has bee particularly active in discussions on the socia responsibilities of psychologists in the internationa field. He has been president of Section J (Psychology of the British Association; and of the British Psychological Society. He has also been Buchanan-Riddell Lecturer in the University of Durham. O his dozen or so books, his first two, "Remembering and Forgetting" and "Skill in Work and Play", hav been perhaps the most influential.

Prof. J. Cohe

DR. JOHN COHEN, who succeeds Prof. Pear, i also a London graduate. He was at Universit College for eight years, under Sir Cyril Burt, an wrote his Ph.D. thesis on the "Statistical Stud of Physical and Mental Types". During the Secon World War he was in the Cabinet Office and spen much of his time as joint secretary of the Wa Cabinet Committee on the Use of Psychologists an Psychiatrists in the Services. Later, as a member o the Working Party on the Recruitment and Trainin of Nurses, he stimulated considerable discussion by an outspoken and cogently expressed minorit report. In 1948 he became lecturer in psychology a Leeds, and in 1949 he was appointed to the chair o psychology in the Hebrew University, Jerusalem Prof. Cohen also is greatly interested in social psychology. He has carried out two investigations fo Unesco, and has been closely associated with th World Federation for Mental Health since its inception. Another of his concerns is the experimental study of higher mental processes. Recently, in addition t lecturing at Birkbeck College, where his scholarlines and integrity have been greatly valued, he has bee engaged on an inquiry for the Acton Society Trus on the effectiveness of working units in relation t their size. He has published papers in the *British Journal of Medical Psychology*, the *Journal of Menta Science*, the *Journal of General Psychology*, th *Eugenics Review*, *Psychiatry*, *Occupational Psycholog* and the *British Medical Journal*.

Proposed British Agricultural History Society

IN the spring of this year, a well-attended meetin was held to consider the formation of a Britis Agricultural History Society. At this meeting small committee was formed to explore the possibi ities. The committee's inquiries were met with promising enthusiasm, and it has now been arrange to hold an inaugural meeting under the chairmanshi of Sir James Scott Watson. The director of th Science Museum, South Kensington, S.W.7, ha allowed this meeting to be held in the Lectur Theatre of the Museum on September 25, at 2.30 p.m The scope of the proposed Society's labours is t cover agriculture in all its phases, human an technical. The social life of all classes of rural societ from the earliest ages is one branch of the subject development of the practice of farming in its hnical and regional aspects is another. The tory of plant and animal breeding, diseases and ir control, and all branches of agricultural science l be included; for example, agricultural chemistry, l science, entomology, mycology, engineering, ilding, land drainage, etc. If sufficient support forthcoming, a periodical containing research pers on all these subjects will be published, nually or more frequently, according to the funds at become available. For the present, Mr. J. W. Y. iggs, Museum of English Rural Life, Shinfield ad, Reading, is acting as honorary secretary, and quiries may be addressed to him. All interested ll be welcome at the meeting at the Science Museum.

The Times Survey of British Aviation"

NOWADAYS there are great expectations for those ho look forward to the annual display and exhibition hich is organized at Farnborough by the Society of itish Aircraft Constructors. The aeroplanes which ave made news in the previous year, month or even eek, are then on show and now, for the first time, ere is *The Times* survey of the whole field published for the occasion (September 1. 1*s*.). This is a served honour since, at least qualitatively, aviation now an important part of our national enterprise. he contributors number some of the most eminent en in the field; and alas, one of them, Mr. John erry, who wrote an article on test-flying, lost his fe through the break-up of a *DH* 110 during the isplay at Farnborough. Some of the photographs of w aeroplanes are spectacular and most are excellent. he survey catches something of the family spirit hich is a part of the equipment of all those engaged British aeronautics—from the industrial apprentice the research scientific worker. From the general ader's point of view, it may be a pity that this irit has here pushed critical analysis into a somehat secondary position so that this issue tends to e a survey only. The problem of the supply of chnical man-power, especially at high level, is arcely considered. Incidentally, there is no mention f the rejuvenating effect of the departments of eronautics in some of the university engineering chools in Britain. Despite the spectacular progress hich has been so strikingly demonstrated, there is s yet insufficient application of scientific technology o some vital problems of design. Can the present rganization of the aeronautical industry adapt itself o life in a peace-time economy?

acao Collecting Expedition in Colombia

A CACAO-COLLECTING expedition to Colombia has een organized by the Imperial College of Tropical griculture, Trinidad, and the Government of olombia, and the advance party, consisting of F. W. ope (plant breeder and expedition leader), R. E. D. aker (plant pathologist) and D. J. Taylor (entomogist), has already commenced work in the forests. urther members are being sent out so that no worker ill spend more than three months in the forest ithout a break. In addition to the British personnel, olombian scientific workers will be participating in he expedition, and also Dr. R. E. Schultes, who has ad much experience in the area collecting *Hevea* pecies for the United States Department of Agriulture. This expedition has been financed by the ritish West Indian and the British West African acao Research Scheme with the full co-operation f the Government of Colombia, and is expected to last for some twelve to fifteen months. The first area to be investigated is the River Apoporis, one of the upper tributaries of the Amazon; and subsequent trips are planned to the Rivers Guaviare, Inirida, Vaupes, Caqueta and to the vicinity of the Casiquiare Bifurcation, the waterway linking the Amazon with the Orinoco. If time permits, short visits will also be made to cacao-growing areas of northern and western Colombia. The expedition plans to follow the main rivers, using aluminium canoes fitted with outboard motors, which can be transported from Bogota, the main base of operations, and from river to river, by Catalina aircraft. It is expected that, in addition to the rivers, it will be possible to use the trails made by the rubber-collectors, and that wild trees of *Theobroma cacao* and of other *Theobroma* and *Herrania* (a genus closely related to *Theobroma*) species will be found scattered or in small groups, but scarcely ever cultivated, throughout the area. The object is to explore the area, which is thought to be one of the homes of Criollo, or high-quality cacao, and thereby to obtain specimens which will widen the existing range of breeding material. Seed and budwood of cacao and of the related wild species will be sent by air to Trinidad and to the Colombian research station at Palmyra.

Progress in French Electronic Instrumentation

ISSUE No. 3, last year, of *Laboratoires*, the quarterly review, in French and English, of French technology, is devoted mainly to electronics and electronic instruments. The opening article is by Prof. P. Grivet who briefly reviews some of the modern applications of electronics. This is followed by a most interesting application of an electron probe and a new method of metallographic spot analysis which has been developed in the laboratories of the Office National d'Études et de Recherches Aéronautiques. If a substance is bombarded by a beam of electrons, X-ray emission is produced and the spectrum of the radiation contains lines which are characteristic of the chemical elements in the bombarded region. By use of electron lenses the beam can be focused and concentrated so that the bombarded region is of very small dimensions, of the order of one micron. An electron microscope has been modified so as to produce the probe, and some of the possibilities of the method and results of experimental tests performed with the apparatus are described. It would appear that the method is rapid and is capable of considerable accuracy. Other articles in the issue are on the mathematical basis of cybernetics, by R. Vallée, vice-president of the French Association of Electronic Engineers, and on the action of short-wave electromagnetic radiations on the maturing of wines, by Prof. M. Lafargue. Finally, there are two articles dealing with medical research: the first deals with electronics in cardiology and describes the various means and apparatus used for observation, analysis, treatment and control; and the second, by Prof. Ch. Oberling, director of the Institut de Recherches sur le Cancer, Villejuif, describes scientific cancer research, its method and tools, with illustrations and details of the particular work carried out at the Institute.

Fluorescent Lighting in Museums

AN article by M. J. Genard, of the University of Liège, originally published in *Museum* (5, No. 1, March 1952) was reprinted, with some additional material introducing the results of more recent research, in the *Museums Journal* of April 1952. A short summary of the latter paper was published in *Nature* of August 23, p. 306. More recently in the *Museums Journal* (June 1952), Messrs. F. I. G. Rawlins (National Gallery) and W. E. Rawson-Bottom (Ministry of Works) have queried some of the statements made in the paper and consider that more specific data should have been obtained in some of the experiments. They have carried out some independent tests and clarified the position as it concerns the museum curator. Their conclusion is that the danger of fading to museum collections exposed to normal fluorescent lighting is negligible.

Rabbit Repellents: a Correction

A review of *Plant Pathology*, a new quarterly journal, appeared in *Nature* of June 21, p. 1050. One of the papers included in this first number concerned the results of trials by H. V. Thompson and C. J. Armour of rabbit repellents for use on fruit trees. The best of these was erroneously given as mixture 96*A*, whereas a mixture of 8 lb. resin in 1 gall. of denatured ethyl alcohol gave the best performance, with only 2 per cent of treated apple stocks showing severe damage.

Present Problems in Nutritional Research: Symposium in Basle

A symposium on "Present Problems in Nutritional Research" will be held in the Kollegienhaus, Petersplatz 1, Basle, during October 1–4 under the auspices of the International Union of Nutritional Sciences. The speakers and their topics will be as follows: Dr. J. Trémolières (Paris), choice of foods; Prof. A. I. Virtanen (Helsinki), natural foodstuffs for nutrition; Dr. D. P. Cuthbertson (Aberdeen), microbiology of digestion, with reference to farm animals; Prof. E. Crasemann (Zurich), energetics of fodder and its metabolism; Prof. E. J. Bigwood (Brussels), free and combined amino-acids in foodstuffs; Prof. K. Lang (Mainz), deterioration of egg-white; Prof. K. Bernhard (Basle), food factors in the prevention of liver-fattening deposits; Prof. K. Thomas (Göttingen), feeding trials with synthetic fatty acids; Prof. O. Högl (Berne), incorporation of additives in food; Prof. E. Abramson (Tomteboda), food additives, including toxic substances; Dr. S. J. Folley (Reading), hormones for nutrition; Prof. A. B. L. Beznák (Birmingham), dietary fat, work and growth; Dr. L. J. Harris (Cambridge), practical significance of vitamins; Prof. H. Dam (Copenhagen), deficiency and mode of action of vitamin E, Prof. H. D. Cremer (Mainz), minerals in foodstuffs; Prof. V. Demole (Lausanne), fluorine and caries; Dr. W. R. Aykroyd (Rome), nutrition work of F.A.O.; Prof. A. G. van Veen (Rome), local foods in supplementary feeding schemes. Participation in the symposium is free. Further information is obtainable until September 30 from *Experientia*, Verlag Birkhäuser AG., Basel, Elisabethenstrasse 15, and after then from the Kollegienhaus, Petersplatz 1, Basel. The secretary of the International Union of Nutritional Sciences is Dr. Leslie J. Harris, Dunn Nutritional Laboratory, Cambridge.

North of England Institute of Mining and Mechanical Engineers

The centenary of the foundation of the North of England Institute of Mining and Mechanical Engineers is to be marked by a meeting during the week beginning September 22 in Newcastle upon Tyne. The meeting opens with a civic reception an luncheon, and includes a centenary dinner, at whic the president of the Institute, Prof. Granville Pool will present the Buddle Medal to Mr. Austin Kirku of the Durham Coal Owners' Association. Pape will be presented during the meeting on the develo ment of the Tyne coal basin (Dr. A. Raistrick), co miners' nystagmus in County Durham (Prof. R. Browne), lighting (Joint Lighting Research Su committee, King's College and the Institute), acc dents from falls of ground (H. F. Wilson and H. Perrins, H.M. inspectors of mines), control of tl strata in mining (Institute's sub-committee on tl subject), pneumoconiosis in Durham and North umberland (Dr. R. I. McCallum, Dr. E. N. Trounson dust suppression (Dr. J. H. Jones), methane emissic (A. B. Dawson), ventilation (Joint Ventilation Su committee, King's College and the Institute), an mechanization of coal mining in the north of Englar (J. S. Raine). Throughout the meeting there w be a mining exhibition in the University School Mines, King's College, Newcastle upon Tyne.

Announcements

Lord Eustace Percy will be president of tl Health Congress to be held at Hastings by the Roy Sanitary Institute during April 28–May 1, 1953.

The fourth post-war annual general meeting an symposium of the Deutsche Gesellschaft fur Fet wissenschaft, Munster, will be held in Dusseldo during October 6–10. The British representativ is Dr. L. Ivanovszky, "Glenbrook", 68 Park Stree Bridgend, Glam.

The Autumn Meeting of the Institution of Nav Architects will be held in Italy during September 25 October 2, in collaboration with the Collegio deg Ingegneri Navali e Meccanici and the Associazion di Tecnica Navale. Meetings for discussion of pape will be held in Genoa (September 26) and Rom (September 29).

An international congress of therapeutics will b held in Madrid during October 16–18 under th presidency of Prof. T. Hernando. The programm will consist of three sections discussing, respectively potassium, massive hormone-therapy and radioactiv isotopes. Further information can be obtained fron the III Congreso Internacional de Teropéutica Instituto de Farmacologia, Ciudad Universitaria Madrid.

An all-day symposium on "Properties of Metall Surfaces", arranged by the Institute of Metals, wi be held in the Lecture Theatre of the Royal Institu tion, Albemarle Street, London, W.1, on Novembe 19 (9.45 a.m.–5.0 p.m.). Attendance at the sym posium is free to all who are interested on applicatio to the Secretary of the Institute, 4 Grosvenor Gar dens, London, S.W.1, from whom further informatio can be obtained.

The University of Padua is offering a Gabriell Zuccari scholarship of 250,000 lire during th academic year 1952–53 for research of at least si months duration at the Zoological Station, Naples The scholarship is open to any person who wishes t undertake research in zoology, comparative anatomy physiology or embryology, and it may be renewed u to a maximum of three years. Application form (to be returned by October 31) and further informa tion can be obtained from the Secretariat of th University of Padua.

SECOND INTERNATIONAL CONGRESS OF BIOCHEMISTRY

THE Second International Congress of Biochemistry was held in Paris at the Sorbonne during July 21-27 and was attended by some two thousand two hundred members from all parts of the world, including about four hundred from Great Britain. Although the large number of adherents proved a surprise and even an embarrassment to the organizers, the arrangements worked with a smoothness which revealed a vast amount of careful preliminary organization by the executive committee under the chairmanship of Prof. C. Fromageot, with Prof. J. E. Courtois as general secretary.

The opening session in the grand amphitheatre of the Sorbonne was attended, in the unavoidable absence of the President of the Republic, by the Minister for National Education, who brought the good wishes of the French Government. The meeting was also addressed by Prof. Gabriel Bertrand, honorary president, by Prof. René Fabre, president of the Congress, and by Prof. C. Fromageot.

Four general lectures were delivered to the congress as a whole: by Prof. J. N. Davidson (Great Britain) on "Nucleoproteins and Tissue Growth" (in English), by Academician A. Oparine (U.S.S.R.) on "Les changements de l'action enzymatique dans les cellules végétales sous l'influence des facteurs exterieurs" (in Russian), by Prof. S. Ochoa (United States) on "Fixation of CO_2 in Animals and Plants" (in English), and by Prof. K. U. Linderstrom-Lang (Denmark) on "Protéines et enzymes" (in French). It is proposed to publish these lectures in the near future.

The main part of the Congress was divided into seven symposia running simultaneously, at which the main papers were moderately comprehensive reviews of recent work given by invitation by recognized authorities on the subjects concerned. These symposia have been published and were available in printed form at the beginning of the Congress. The symposia were supplemented by short communications given by members of the Congress at large.

In symposium No. 1, for example, on the "Biochemistry of Hæmopoiesis", H. G. Wijmenga (Holland) and M. S. Shorb (United States) reviewed recent work on the chemistry and microbiological assay respectively of the cobalamins (the vitamin B_{12} group), while the role of folic acid and the citrovorum factor was dealt with by E. L. R. Stokstad (United States). A most useful review of the metabolism of metals in hæmopoiesis was given by S. Granick (United States), who, as might be expected, dealt chiefly with iron and the importance of ferritin in its absorption and utilization, but who included the parts played by copper, cobalt, molybdenum and zinc. This led naturally to the bone marrow (M. Errera, Belgium) and to the utilization of proteins in blood cell formation (A. Aschkenazy, France). A. Neuberger (Great Britain) surveyed the important recent work on the biogenesis of the hæmin pigments with particular reference to porphyrin formation and the porphyrias, while M. F. Perutz (Great Britain) covered the structure of hæmoglobin.

The complex subject of the "Biogenesis of Proteins" was discussed in symposium No. 2. It opened with a masterly account by J. S. Fruton (United States) of peptide bond synthesis, which was followed by a discussion of the molecular kinetics of proteolytic enzymes by H. Neurath (United States) and of the role of glutamine, asparagine and glutathione in biosynthesis, by H. Waelsch (United States). The general problem of enzymatic peptide synthesis was dealt with in some detail by H. Borsook (United States), while the more specialized aspects of the formation of specific proteins were discussed by other speakers—milk proteins by T. S. Work (Great Britain), serum proteins and antibodies by F. Haurowitz (United States), procollagens by V. N. Oriekhovitch (U.S.S.R.), *iso*hæmagglutinins by R. Wurmser (France), penicillinase by M. R. Pollock (Great Britain) and adaptive enzymes by J. Monod (France). The vexed question of the function of ribonucleic acid in protein synthesis was surveyed by H. Chantrenne (Belgium), and the curious phenomenon of long-range enzymatic action by A. Rothen (United States) and by J. Winter (France).

Perhaps the symposium which aroused the greatest general interest was No. 3, on the "Tricarboxylic Acid Cycle". H. A. Krebs (Great Britain) introduced the subject by discussing the place of the cycle in cell metabolism, and was followed by C. Martius (Germany) and S. Ochoa (United States), who concentrated on certain detailed aspects. In such a discussion as this it was natural that coenzyme A should be dealt with in detail. F. Lipmann (United States) gave a general survey of its importance and discussed in detail recent studies on the synthesis of acetyl-coenzyme A by way of the interaction of adenosine triphosphate, coenzyme A and acetate which has led to the discovery of coenzyme A-pyrophosphate. The importance of the cyclophorase system was fully reviewed by D. E. Green (United States). This paper and the following one by F. Leuthardt (Switzerland) emphasized the importance of the mitochondria in the internal economy of the cell both in relation to the process of oxidation and to the formation of urea by the linking of the arginine cycle with the metabolism of glutamate and malate.

The biochemical dissection of some steps in the tricarboxylic acid cycle by means of inhibitors, and in particular its specific inhibition by toxic fluoro-compounds, was described by Sir Rudolph Peters (Great Britain), while alternative pathways and variations in the cycle were discussed by E. S. Guzman Barron (United States). No discussion of the citric acid cycle would be complete without reference to its role in fatty acid oxidation, which was ably reviewed by F. L. Breusch (Turkey). The final paper in this symposium was by W. A. Engelhardt (U.S.S.R.) on the enzymology of myosin.

Symposium No. 4, on "Hormones related to Proteins", provided a more miscellaneous collection of material. S. J. Folley (Great Britain) discussed the hormonal control of the initiation and maintenance of lactation with special reference to the adrenal cortex and insulin. The opposing actions of these hormones was illustrated by the observation that the potentiating effect of insulin on lipogenesis from small molecules could be diminished or abolished by cortisone. F. Sanger (Great Britain) reviewed his recent important work on the structure of insulin, for which the complete amino-acid sequences of fractions *A* and *B* are now available. *nor*Adrenaline was discussed by U. S. von Euler (Sweden), and the biologically important amines by Z. M. Bacq (Belgium). The recent work of the Cambridge school on the metabolic influence of the pituitary growth hormone was ably surveyed by F. G. Young (Great Britain). R. Michel (France), in a remarkably thorough survey of the thyroid hormone, discussed the biogenesis of thyroxine, the formation and proteolysis of thyroglobulin and the nature of the circulating hormone.

It was not surprising to find that the fifth symposium, on the "Metabolism of Micro-organisms", was also very varied in content. E. Chargaff (United States) discussed the nucleic acids of micro-organisms, a subject which was also touched on by D. D. Woods (Great Britain) in his paper on the formation of folic acid and related growth factors. The surprising versatility of the various active forms of vitamin B_6 in enzymic reactions was clearly brought out by E. E. Snell (United States), while the lipids of the mycobacteria were reviewed in a comprehensive fashion by E. Lederer (France). Three papers dealt with the formation and metabolism of aromatic compounds. B. E. Davis (United States) and G. Ehrensvärd (Sweden) gave stimulating reviews of the biosynthesis of aromatic rings, and R. G. Stanier (United States) dealt with their oxidation.

The metabolism of micro-organisms featured prominently also in symposium No. 6, on the "Mode of Action of Antibiotics". W. W. Umbreit (United States) explained that streptomycin inhibited a reaction between oxalacetate and pyruvate which is lost in resistant cells. Both E. F. Gale (Great Britain) and F. Gros (France) emphasized the profound changes in nucleic acid metabolism and in protein metabolism (particularly the blocking of the uptake of glutamic acid) which take place in micro-organisms treated with penicillin. *Staphylococcus aureus*, for example, grown in presence of penicillin, produces derivatives of uridine-5′-pyrophosphate which were described by J. T. Park (United States). Discussion of the mode of action of antibiotics led naturally to the question of resistance, the genetic aspects of which were dealt with by L. L. Cavalli (Italy). R. D. Hotchkiss (United States) described how penicillin-sensitive rough-strain pneumococci give rise to a proportion of penicillin-resistant variants when grown in the presence of the deoxyribonucleic acid prepared from rough strains selected for spontaneously arising penicillin resistance. Finally, S. Americano-Freire (Brazil) gave an extensive account of the antibiotic properties of *p*-amino salicylic acid and its phenyl ester in experimental tuberculosis.

The seventh and last symposium dealt with "Steroids". The question of the relationship between chemical structure and biological activity was discussed for steroids in general by C. W. Shoppee (Great Britain) and for their 6-hydroxy derivatives by M. R. Ehrenstein (United States). G. Pincus (United States) dealt all too briefly with his recent fascinating work on steroid biosynthesis in the isolated perfused adrenal gland while W. Dirscherl (Germany) surveyed the effects of steroids on enzymatic reactions and metabolic processes. The urinary excretion of steroids and its clinical significance was discussed by E. R. Venning (Canada), G. F. Marrian (Great Britain), L. G. Huis in't Veld (Holland) and M. F. Jayle (France).

It was, of course, clear to the organizers of the Congress that all the original papers submitted by members could not be incorporated into the framework of the seven symposia. Such communications were therefore given in the most appropriate of the thirty-one different sections, which met in the afternoons and covered the following fields of biochemistry (1) mineral elements ; (2) lipids ; (3) amino-acids and proteins ; (4) nucleoproteins ; (5) pigments ; (6) fat-soluble vitamins ; (7) water-soluble vitamins ; (8 enzymes and coenzymes ; (9) carbohydrases ; (10 esterases ; (11) phosphatases and depolymerases (12) proteases ; (3) oxidases and dehydrogenases (14) carbohydrate metabolism ; (15) amino-acid metabolism ; (16) sulphur metabolism ; (17) fermentations ; (18) plant chemistry ; (19) plant metabolism ; (20) photosynthesis ; (21) nutrition (22) biochemistry of ossification ; (23) clinical chemistry ; (24) immunochemistry ; (25) blood clotting ; (26) muscle biochemistry ; (27) physiological chemistry and pharmacodynamics ; (28) chemotherapy ; (29) biochemical effects of ultrasonics ; (30) chemistry of cancer ; (31) apparatus and techniques.

The lighter side of the Congress involved a large number of social functions, including a special performance of ballet at the Théatre National de l'Opéra and a whole-day excursion to Chantilly and Compiègne.

At the closing session of the Congress, with Prof. Fabre presiding, Prof. J. N. Davidson, who was deputizing for Sir Charles Harington as chairman of the International Committee, announced that an invitation had been received to hold the Third International Congress of Biochemistry in Brussels in 1955. Expressions of appreciation of the work of the French organizers were given formally by Prof. A. Tiselius (Sweden), Sir Rudolph Peters (Great Britain), Academician A. Oparine (U.S.S.R.), Prof. S. Ochoa (United States) and Prof. E. J. Bigwood (Belgium).

SOCIETY FOR APPLIED BACTERIOLOGY

SUMMER CONFERENCE IN CAMBRIDGE

THE summer conference of the Society for Applied Bacteriology was held during July 22–24 in Newnham College, Cambridge, and included a symposium, sessions for reading papers and visits to places of interest. At the annual general meeting, Dr. J. G. Davis (London) was elected president for the ensuing two years. The secretary of the Society, from whom further information can be obtained, is G. Sykes, of Boots Pure Drug Co., Ltd., Nottingham.

The symposium, to which contributions were made by H. B. Hawley (Yeovil), M. Ingram (Cambridge), R. S. Hannan (Cambridge), A. Hirsch (Bedford), N. R. Knowles (Belfast), and Miss M. P. Scarr (Bromley), was on "Aspects of Food Preservation". In introducing the subject Mr. Hawley described the origin and some of the earlier methods of food preservation and then, having outlined the principles required, gave some of the modern chemical, physical and biological methods in use. Dr. Ingram discussed the possibility of sterilization by high-frequency voltage fields using a voltage gradient of 1,000 V./cm. Heating during treatment is a major problem, and special precautions and apparatus have to be used to keep the test material cool. He described various types of apparatus and pulsation treatments employed experimentally, and as found that, when temperature effects are elim-ated, there is no evidence of significant lethal ction on yeast cells, *Bacterium coli* or on bacterio-hage. Earlier reports on the apparent success of he treatment must be attributed to heating effects.)r. Hannan described sterilization experiments with igh-energy electrons using an electron accelerator iving 0·1–15 MeV. or using gamma-rays from obalt-60 with energies of 0·7 and 1·2 MeV. By radiation from two sides the electrons can penetrate niformly and effectively up to 10 cm. depth and he gamma-rays rather more deeply. Certain de-terious side-effects can be avoided by pre-freezing. pinions are not in entire agreement on the actual thal doses for micro-organisms, but in general ·2 × 10^6 roentgens kill vegetative bacterial cells, nd 0·5–2 × 10^6 r. bacterial spores; bacteriophage s more resistant than bacterial cells or enzymes. 'he dose required to kill is dependent on a number f factors, including the suspension medium and xygen tension. The system appears to be economic-lly possible and would have wide applications in he pharmaceutical field. In his paper on "Anti-iotics in Food Preservation", Dr. Hirsch said that, n general, antibiotics have been used experimentally)r the preservation of certain non-acid foods, the ain organism to be dealt with being *Cl. botulinum*. ubtilin is of some value with canned peas, but in eneral the method does not appear to be practicable. Jisin has been used in cheese to prevent growth of *lostridium* species (mainly *Cl. butyricum*); this anti-iotic appears to be more effective in inhibiting ermination of spores than development of vegetative ells.

Describing his observations on "The Microbiology f Raw and Heat-treated Liquid Egg", Mr. Knowles aid that fresh-laid eggs are practically sterile intern-lly, but low-grade eggs may contain many millions f bacteria per gram. On hard freezing, the viable acterial population may be reduced by up to 55 per ent. Duck eggs are generally more heavily contam-ated, carrying, in particular, Salmonella bacteria. 3y careful organoleptic control, the quality of raw en eggs used for liquid egg preparation has recently een improved so that bacterial counts have been uch reduced, and a suggested standard of less than × 10^6 viable bacteria per gm. would be meri-orious. Heat treatment is carried out at 149–150° F. 55–65·5° C.) for three minutes in a modified plate asteurizing plant. This reduces the bacterial count o less than 1,000/gm., but careful control is necessary o reduce coagulation deposits on the plates. Miss carr, in her paper on "The Microbiology of Sugar-reserved Foods", dealt particularly with the pro-erties of osmophilic yeasts and moulds, and discussed he types usually found as contaminants and their daptability. Spoilage occurs either through growth f these resistant organisms or from local dilution f syrups brought about by condensation in the sur-ice.

Papers given at other sessions included three on e detection and classification of organisms of the oli-aerogenes group. The first, by N. P. Burman nd C. W. Oliver (London), showed that Folpmer's lutamic acid medium is somewhat superior to lacConkey medium in detecting *Bact. coli* in water; nother by T. Richards and M. T. A. Fouad (Reading) scussed the use of inorganic media containing ucose in the classification of the group, and a ird, by S. B. Thomas and colleagues (National gricultural Advisory Service), reviewed the significance of the coli-aerogenes and *Bact. coli* assessments from more than 2,500 samples of farm waters. W. A. Hoy and L. F. L. Clegg (Shinfield) described a new test for dairy disinfectants using aged milk in soiled churns. Results obtained suggest that they might parallel those from longer-termed field trials. Miss C. Higginbottom and D. W. F. Wheater (Hannah Dairy Research Institute) discussed the occurrence of *Streptococcus bovis* in rumen contents, showing that there is a significant increase during the first hour after feeding; Mrs. A. C. Stirling (Edinburgh) indicated the importance of lactobacilli in silage to ensure a rapid fall in *p*H value and so reduce nutritional losses.

From the public health aspect, A. Clarenburg (Utrecht) discussed the occurrence of Salmonella bacteria in meat. Outbreaks of poisoning from this source are usually traced to meat products rather than raw meats, and carrier animals increase the complications. E. B. Reid and M. Woodbine (Aberdeen) demonstrated the 'Pressfish' process for preparing vacuum-dehydrated foods and discussed the microbiology concerned, and a paper by S. E. Jacobs and Miss M. J. Thornley (Ambleside), on the effect of ultrasonic waves on bacteria suspended in milk, showed that treatment at 20 kW. or at 1 Mw. is only partially lethal to a variety of bacteria, increased protection apparently being afforded by the high protein content. A. M. Paton and T. Gibson (Edinburgh) described an improved technique for assessing microbiological lipase activity, and Miss J. P. Cowne and J. R. Postgate (Teddington) an improved medium for estimating sulphate-reducing bacteria by dilution counts. The normal medium is supplemented with sodium sulphide and cysteine or ascorbic acid, rendering sulphate-reducers easily detectable by the precipitation of black ferrous sulphide.

INSTITUTE OF PHYSICS

ANNUAL GENERAL MEETING

AT the thirty-second annual general meeting of the Institute of Physics, held on June 5 at the Institute's House, 47 Belgrave Square, London, S.W.1, the following were elected to take office on October 1: *President*, Dr. C. Sykes; *Vice-Presidents*, Mr. O. W. Humphreys and Dr. T. L. Ibbs, *Honorary Treasurer*, Dr. S. Whitehead; *Honorary Secretary*, Dr. B. P. Dudding; *New Ordinary Members of the Board*, Mr. H. Barrell, Dr. N. A. De Bruyne, Dr. W. H. Taylor and Mr. R. G. Wood. Prof. W. E. Curtis and Dr. F. C. Toy (past-presidents), Prof. E. G. Cox and Dr. J. Topping (vice-presidents), Mr. T. C. Keeley, Mr. G. R. Noakes, Dr. H. L. Penman and Prof. S. H. Piper continue to serve on the Board. Sir Owen W. Richardson was elected to honorary fellowship of the Institute.

The thirty-second annual report of the Board, covering the work of the Institute during 1951, was adopted at the meeting. It records that the Board met six times, and its various standing committees nineteen times, during the year. The membership increased by 222 to 4,080. Applications for election or transfer to the various grades of membership of the Institute received during 1951 numbered 524, compared with 627 in the previous year. There was a slight decrease in the number of subscribers and students, but substantial increases in the numbers in the other grades, particularly in the recently established grade of graduateship. The regulations and syllabuses for the graduateship examination which were published during the year aroused wide interest, and the number of candidates for the first graduateship examination, held recently, was greater than was anticipated. The regulations governing election to the associateship grade were modified to permit the admission of candidates whose training in physics is adequate but who may have graduated in subjects other than physics.

The number of candidates who presented themselves for the 1951 examination for National Certificates in Applied Physics was substantially greater than in the previous year; twelve colleges entered candidates at the ordinary level and five at the higher stage. Nine technical colleges which have applied for recognition, or for an extension of recognition, as institutions approved by the Institute for the education and training of physicists, were inspected.

In 1949 the Board decided that the Institute should rapidly increase the volume of its publications, and although this development has been somewhat restricted by printing and other delays and the substantial rise in the cost of printing and paper, it has largely been implemented. In addition to its two journals, the *Journal of Scientific Instruments* and the *British Journal of Applied Physics*, and its monthly *Bulletin* to members, two further monographs in the "Physics in Industry" series were published. Other books published for the Institute (issued by Edward Arnold and Co.) were "Some Aspects of Fluid Flow" containing the papers presented at a conference organized by the Institute in October 1950; "Bibliography on Electron Microscopy", edited by Dr. V. E. Cosslett for the Institute's Electron Microscopy Group; and a further selection of laboratory and workshop notes from the *Journal of Scientific Instruments*, prepared and edited by Dr. Ruth Lang. A new development is the Board's decision to sponsor a series of small books suitable for university students and those studying for Higher National Certificates in Applied Physics, each of which will cover some branch of applied physics and be written by an authority in that field. It is hoped to launch the series shortly.

In addition to individual inquiries from members concerning professional matters, the Board has considered the Ministry of Labour's report on the supply of and demand for physicists, the right of travel for men of science and the part-time employment of retired members; and it has issued an informative report on the second survey of salaries and emoluments paid to fellows and associates of the Institute resident in Great Britain and Ireland. The Institute is represented on the Parliamentary and Scientific Committee and the Joint Council of Professional Scientists, and thus keeps in close touch with science in the government service and ensures that proper regard is given to the scientific point of view in the political sphere.

The fifteen local branches and specialist subject groups of the Institute held more than a hundred meetings during the year. Details of the various activities of the branches and groups are listed in the report. A new event was the very successful exhibition of scientific instruments and apparatus arranged by the Australian Branch in Melbourne, which attracted some four thousand visitors during the four days it was open to the public. The Branch committee ha given consideration to a proposal that an independen Australian Institute of Physics be established, an the Board of the Institute has intimated that, if th proposal should receive the support of the Australia members, it would welcome the development. Th London and Home Counties Branch, under the chai manship of Dr. A. J. Maddock, held a summer meetin at the Cavendish Laboratory, Cambridge, and an 'a home' at the Institute's House in October. Th Education Group held meetings in Birmingham (i conjunction with the Midland Branch) and Mar chester (with the Manchester and District Branch together with a joint meeting at Cambridge with th Electronics Group, and a three-day conference i London; it also visited the Royal Naval Colleg Greenwich. The X-Ray Analysis Group held its usu two conferences, has continued its work on th extension of data for the card index of diffractio data published by the American Society for Testin Materials, and has published a memorandum on th preparation and mounting of polycrystalline spec mens for X-ray analysis. It is interesting to note th the National Committee of Crystallography, on whic the Board is represented, has directed the attentic of the X-Ray Analysis Group to the fact that th fortieth anniversary of the discovery of X-ra diffraction falls in 1952. It has since been announce that a commemorative meeting will be held durin October 24–25 at the Royal Institution (see *Natur* June 7, p. 949).

COST OF GERMAN MEDICAL AND SCIENTIFIC PERIODICALS

By DR. W. BONSER
University Librarian
AND
MARGARET P. RUSSELL
Deputy Librarian, Medical School, University of Birmingha

THE exorbitant cost of German medical an scientific periodicals has once again become th concern of those who budget for university and oth learned libraries. The cost of English periodicals h continued to rise, although slightly, owing to i creased cost of publication; still more has the cost American periodicals risen, not only on account devaluation but also on account of similar productio increases in the United States as well. But the co of German periodicals has exceeded those to a alarming extent, and appears to be settling down at figure which will make it impossible for many Britis libraries to continue their subscriptions.

A parallel situation arose after the First Wor War, and a united effort by those affected—conduct in the pages of *Nature*—succeeded in achieving reduction of 20 per cent in 1933 and a further redu tion of 25 per cent in 1935, conceded after a fall value of the pound sterling. The pre-war complain were not only of the excessive cost compared w that of British periodicals of a similar nature a size, but also of the impossibility of computing t annual cost, owing to irregularity in the number volumes per year. This same state of affairs regre tably still obtains.

An analysis of costs of a selection of representati medical journals in similar subjects from Gre

Britain, the United States, other European countries, and Germany (for example, *Journal of Physiology*, *American Journal of Physiology*, *Archives internationales de Physiologie*, *Pflügers Archiv*) has been made for the years 1938–39, 1950 and 1951, and shows that in these last two years the cost of German journals exceeded the combined sum expended on the others, although the increase on account of devaluation of sterling amounted to 45 per cent for American, and 26 per cent only for German periodicals. Compared with 1933, the totalled prices of the sets of journals in the four categories, taking the average of 1950 and 1951 in each case, may be presented in simple ratio as follows :

	British	American	Other countries	Germany
1933	1·0	1·06	0·875	3·8
1950–51 (averaged)	1·0	1·69	0·96	4·15

showing that the case for a reduction in price of German periodicals holds again.

A further table has been compiled showing that of these German periodicals from different publishing houses, those emanating from the Springer Verlag are three (3·2) times the cost of the others, and although the 1951 figures for Springer publications show a reduction on 1950 prices, the fall would appear to be due not to a reduction in price but to one in output.

We are told by experts that the post-war value of German scientific and medical periodicals is scarcely yet up to pre-war standard, but is still of high enough quality to justify their purchase by those who can afford them. It is obvious that German scientists will do their utmost to achieve the highest standard, and we are assured that they are prepared to co-operate in this effort to reduce the excessive price of their journals. We are sure it will be agreed that their output is as essential to research as that of other countries, and curtailment of its circulation owing to prohibitive costs is to be deplored. American librarians are equally anxious to find a solution to this problem, as has been evidenced in our correspondence with them.

It is impossible to print here the full text of this nvestigation, done in 1950 and revised for 1951 ; but a copy will be sent on request to those interested.

FUNDAMENTAL PARTICLES

SCIENCE PROGRESS of April (40, No. 158, 193 ; 1952) contains an interesting and informative article by Prof. H. S. W. Massey entitled "Fundamental Particles", the term which is applied usually to such entities as electrons, protons, etc. Prof. Massey points out, however, that the quantum theoretical description of the physical world is a dualistic one in which mechanical phenomena are viewed from both a particle and a wave aspect and that classical physics is the limiting case when h, Planck's constant, tends to zero. It is better, therefore, when describing the fundamental nature of matter and radiation to begin with the purely wave description and then, by imposing quantization, to lead to the particle aspect.

It is Prof. Massey's contention that the general features and consequences of the application of quantum theory to wave fields can be made clear without the use of elaborate mathematics and can be appreciated without a detailed knowledge of physics, and after reading his admirable article the reader will doubtless agree with Prof. Massey. The quantized electromagnetic field and its associated particles, the photons, are dealt with first, then the electron field and finally the interaction between the two fields. It is shown that at no stage is it necessary to postulate action at a distance, but that the necessary interaction between particles can be transmitted through the electromagnetic field vacuum photons.

Turning next to the subject of the classification of the fundamental wave particles, Prof. Massey shows that the particles can be loosely separated into three categories, which he aptly terms "building stones" (electron, proton and neutron), "cements" (photon and pi-meson) and "bric-a-brac" (neutrino, mu-, V-, tau- and kappa-mesons). The first two categories, as their names imply, are involved in the structure of matter, but the third, apparently, does not fulfil any important role in that respect. The properties of the various particles and the relations between them are briefly and clearly described, and it is evident that their number (now some twenty-four) is far too large for them all to be fundamental. Nevertheless, as Prof. Massey states, the discovery of new particles is still a prominent feature of modern physics, and thus, until some new fundamental advance or simplification is made on the theoretical side, not only to provide a basis for the "bric-a-brac" but possibly also to account for the more complete range of particles yet to be explored, the fundamental scheme of Nature must remain obscure.

S. WEINTROUB

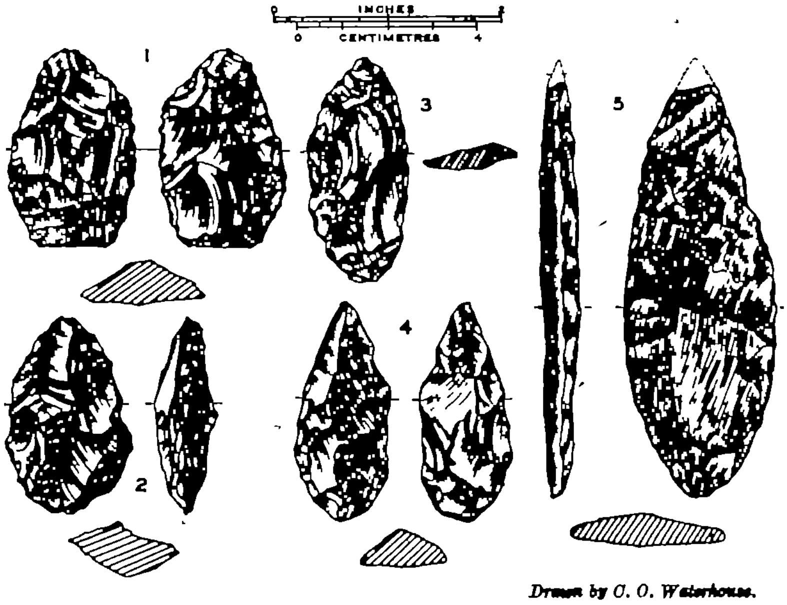
DATING THE LIBYAN DESERT SILICA-GLASS

By DR. KENNETH P. OAKLEY

Department of Geology, British Museum (Natural History)

PIECES of natural silica-glass up to 16 lb. in weight occur scattered sparsely in an oval area measuring 130 km. north to south and 53 km. from east to west, in the Sand Sea of the Libyan Desert. This remarkable material, which is almost pure (97 per cent SiO_2), relatively light (sp. gr. 2·21), clear and yellowish-green in colour, has the qualities of a gemstone. It was discovered by the Egyptian Survey Expedition under Mr. P. A. Clayton in 1932, and was thoroughly investigated by Dr. L. J. Spencer, who joined a special expedition of the Survey for this purpose in 1934.

The pieces are found in sand-free corridors between north–south dune ridges, about 100 m. high and 2–5 km. apart. These corridors or 'streets' have a rubbly surface, rather like that of a 'speedway' track, formed by angular gravel and red loamy weathering debris overlying Nubian Sandstone. The pieces of glass lie on this surface or partly embedded in it. Only a few small fragments were found below the surface, and none deeper than about 1 metre. All the pieces on the surface have been pitted or smoothed by sand-blast. The distribution of the glass is patchy



Drawn by C. O. Waterhouse.

PROBABLE ATERIAN ARTEFACTS FROM LIBYAN SAND SEA

(1) Miniature foliate 'hand-axe' in silica-glass; plano-convex; probably made from thick flake. The straight basal margin is a natural surface pitted by sand-blast. The *arêtes* of the flake-scars are slightly smoothed. Brit. Mus. (Nat. Hist.) Geol. Dept. *E.* 1454

(2) Miniature foliate 'hand-axe' in silica-glass. The narrow area on one face which shows shallow pitting is a remnant of a surface which was sand-blasted before the material was worked. The flaked surfaces are slightly smoothed by sand-blast. *E.* 1453

(3) Thin, twisted, bifaced foliate point in silica-glass. Slightly smoothed by sand-blast Perforated by meandering tubular cavity, 0·6–1·5 mm. in diameter, which is blocked at the narrower end by a particle of loam. *E.* 1455

(4) Bifaced foliate point in silica-glass; plano-convex; probably made from a flake All the edges are smoothed by sand-blast, the convex surface considerably so. *E.* 1456

(5) Bifaced foliate point in quartzite. Tip broken. Slightly worn by sand-blast. *E.* 1452

(ref. 1, see map, p. 434). It was found to lie most thickly around the expedition's Camp 7 (lat. 25° 17′ 54″ N., long. 25° 34′ 0″ E.). At several places there were groups of flakings, evidently where large lumps had been broken up by man. Only two small fragments were found upon the dune ridges. They occurred in company with an implement of quartzite and had evidently been carried there. One piece of silica-glass was found 240 km. south by east of the main area of distribution, and another piece 225 km. to the east-south-east. These, too, had probably been transported by man.

While undoubtedly natural, the origin of the Libyan silica-glass is uncertain. In its constitution it resembles the tektites of supposed cosmic origin, but these are much smaller. Tektites are usually black, although one variety found in Bohemia and Moravia and known as moldavite is clear deep green. The Libyan silica-glass has also been compared with the glass formed by the fusion of sand in the heat generated by the fall of a great meteorite, for example, at Wabar in Arabia and at Henbury in Central Australia. Reporting the findings of his expedition, Dr. Spencer (ref. 2, p. 506) said that he had not been able to trace the Libyan glass to any source; no fragments of meteorites or indications of meteorite craters could be found in the area of its distribution. He said: "It seemed easier to assume that it had simply fallen from the sky".

It would be of considerable interest if the time of origin or arrival of the silica-glass in the Sand Sea could be determined geologically or archæologically. Its restriction to the surface or top layer of a superficial deposit suggests that it is not of great antiquity from the geological point of view. On the other hand, it has clearly been there since prehistoric times. Some of the flakes were submitted to Egyptologists in Cairo, who regarded them as "late Neolithic or pre-dynastic" (ref. 3, p. 504). In spite of a careful search by Dr. Spencer and the late Mr. A. Lucas, no objects of silica-glass could be found in the collections from Tut-ankh-Amun's tomb or from any of the other dynastic tombs. No pot-sherds were encountered in the silica-glass area, but in the neighbourhood of the flakings some "crude spear-points of glass" were found, also some quartzite implements, "quern stones" and ostrich-shell fragments (ref. 1, pp. 433, 435).

In the hope of throwing more light on the date of origin o silica-glass in the Sand Sea, al the artefacts of this materia which Dr. Spencer deposited in the British Museum (Natura History) have been re-examined together with those of other materials from the same area which he brought to England.

The artefacts collected were mainly from workshop sites in the region of Camp 7 in Street *B* and in the neighbouring parts of Street *A* to the west (19 km north of Camp 9) and of Street *C* to the east (west of Camp 10). The material preserved in the Departments of Mineralogy and Geology in the British Museum (Natural History) comprises: two bifaced foliate points, two small bifacial tools (miniature 'hand-axes'), one atypical core and more than 22 flakes and flake-blades of silica-glass; one bifaced foliate point and nine flakes and flake-blades o quartzite (silicified Nubian sandstone); two pieces of hæmatite. (These pieces of hæmatite were presumably brought into the area by man. The so-called quernstones, found, for example, in Street *C* in proximity to quartzite flakes, were probably for grinding hæmatite into red ochre (ref. 4, p. 71). A typical pair comprised a large flat lower stone o partly silicified Nubian sandstone, and a smaller bun-shaped upper stone (an oval boulder of the same sandstone, but of much coarser grain).)

All the flaked artefacts are of palæolithic facies The flakes of silica-glass include a few large Clactonoid forms (that is, struck by the elementary *bloc-on-bloc* technique), while several are Levalloisoid (that is struck from prepared cores). Many of the quartzite flakes and flake-blades are Levalloisoid. Indeed, since they show faceted striking-platforms in addition to evidence of preparation of the face of the core, they may be described with little hesitation as Levalloisian. In comparing the typology of the artefacts of the two materials, it has to be remembered that whereas any flake of silica-glass would have been kept by the investigators, the rougher flakes of quartzite would probably have been neglected. Moreover, the flaking qualities of quartzite and silica-glass are very different A high percentage of the flakes of silica-glass are o e narrow form now called 'flake-blades' (ref. 5, 91), and include curving spalls up to 9 cm. long ef. 3, p. 504). It is noteworthy that the collection cludes no true blades (that is, made by the punch-chnique); nor does it include any microliths.

The *bloc-en-bloc* and prepared-core techniques were ed in Africa by various cultural groups extending er a long range of time, so that the Clactonoid and evalloisoid flakes are not closely diagnostic of the e or cultural status of the silica-glass workshops. owever, there are five artefacts in the collection ted above, all from Camp 7, and four of them in lica-glass, which indicate the Late Palæolithic lture known as Aterian—that is, the bifaced liate points and the miniature 'hand-axes' (see lustration). The bifoliate points are the "crude ear-points of glass" noted by Dr. Spencer (ref. 1, . 433). These figured specimens are now in the epartment of Geology of the British Museum Natural History).

These artefacts can be closely matched in the terian industries which occur in Morocco, Algeria d sparingly farther east, for example, in the harga Oasis (ref. 6). The Aterian is based on a evalloiso-Mousterian ('Middle' Palæolithic) tradition, d is akin to the Still-Bay industries of the southern alf of Africa. It is distinguished by the absence of e true blade elements which characterize the suc-eeding Capsian group of industries. Commonly per cent or more of the artefacts in an Aterian dustry are flake-blades (ref. 5, p. 121). The associa-on of bifaced foliate points with certain types of and-axes', including miniature forms, is one of the atures of the Aterian industries noted by Miss aton-Thompson (ref. 5, pp. 91, 97). The type-artefact f Aterian culture is the tanged-point, or arrow-head. t is regrettable that none is represented in the ollection of silica-glass artefacts which has been xamined (but it is perhaps worth recording that one f the pointed flake-blades from Camp 7 is accident-lly pedunculate and most deceptively simulates the orm of a blunted Aterian arrow-head).

While the only well-defined artefacts in silica-glass rom the Sand Sea are almost certainly Aterian, one not justified in concluding that all the flakings in his material are of the same age. Some may well be ounger; for example, any which are contemporary ith the ostrich-shell fragments and grinding stones re probably not older than Upper Sebilian (Meso-thic). But more important from the point of view f the present inquiry is the question of whether any re *older* than Aterian.

Some of the larger flakes of silica-glass might well e Early Palæolithic (Acheulean) waste-flakes; but hey could equally well be the primary or 'quartering' akes of an Aterian industry. Similarly, although heir proximity to bifaced foliate points strongly uggests that they are Aterian, the miniature 'hand-xes' described above might be exceptionally small cheulean hand-axes. However, it is true to say that o undoubtedly pre-Aterian artefact in silica-glass as been found.

At a point 24 km. south of Camp 8 in Street *D*, ixty large quartzite hand-axes of Upper Acheulean ype were discovered lying on the surface with lossy sand-worn faces uppermost (ref. 1, p. 435). A ew were deposited in the Cairo Museum; others vere left *in situ* for further investigation. I have xamined one specimen, regarded as typical of the roup. It is a symmetrical biface with Gothic-arch ip, true-edged, 21 cm. long, 10·5 cm. wide, and with maximum thickness of slightly less than 5 cm. Associated with these large hand-axes there were quartzite waste-flakes. At the same site there were scattered pieces of silica-glass, but none appeared to have been worked. If Acheulean hunters had encountered silica-glass in pieces as large as those occurring, for example, in Street *C* about 10 km. to the west-north-west, it seems probable that they would have attempted to use it as raw material for hand-axes, just as they used the volcanic glass (obsidian) at Kariandusi in the Kenya Rift Valley (ref. 7, p. 36). The fact that no undoubted Acheulean artefacts in silica-glass have been found cannot be regarded as proving that this material was absent from the region during the period of that culture; for it is possible that such artefacts occur, but have not yet been found or recognized. Another possibility is that attempts by the Acheuleans to work the material into large hand-axes were unsuccessful owing to its brittleness and the consequent wastage. It must be remembered that large pieces of silica-glass may have been rare even at the time of its origin, whereas the supplies of obsidian at Kariandusi were probably large enough to allow considerable wastage in the manufacture of hand-axes.

Thus the archæological evidence allows us to go no further at present than to conclude that silica-glass was present in the Libyan Sand Sea in Late Palæolithic (Aterian) times. But it is important to bear in mind that the glass was already corroded by sand-blast before it was worked into the bifaced points. It should be noted here that the Acheulean and Aterian cultures may have been separated by a considerable interval, corresponding to the time when the basic Levalloiso-Mousterian culture flourished. The Aterian was technologically a derivative of the Levalloiso-Mousterian, and is now considered to have been broadly contemporary with the 'Aurignacian' and Solutrean cultures of Europe—that is to say, it has a probable antiquity of between 10,000 and 20,000 years.

Several artefacts of natural green glass (moldavite) were found in the 'Upper Aurignacian' (Gravettian) levels in the loess at Willendorf in Lower Austria (ref. 8), and one example, apparently from a Mousterian horizon, in the Gudenus Cave in the same region (ref. 9). It is also interesting to note that tektites have been found in the Trinil beds of Java, which are considered to be of about the same age as deposits containing remains of Acheulean culture in the west, that is, Middle Pleistocene (ref. 10). Thus the suggestion that Libyan silica-glass, moldavite, and other tektites represent 'glass-meteorites' which reached the earth within a limited period of time (ref. 11) at least appears consistent with the rather meagre archæological and geological evidence.

In conclusion, I should like to express my thanks to Dr. L. J. Spencer for the help he has given me in the preparation of this article.

MISCIBILITY OF LIQUIDS INFLUENCED BY RATE OF SHEAR

By A. SILBERBERG and PROF W. KUHN
Institute of Physical Chemistry, University of Basle

WHETHER or not phase separation will occur in a liquid system is a question of the mutual solubilities of its components. It is usually assumed that, if pressure and relative composition are held constant, the temperature alone determines these solubilities and thereby decides the question of demixtion, that is, the general phase state of the system. From experiments which we have performed it appears, however, that the assumption of complete determination of solubility by temperature at constant pressure and relative composition requires considerable amendment. Our results show that in the case of certain demixed liquid–liquid systems the maintenance of a field of flow (stirring) can affect the solubility and thereby the miscibility of the phases as profoundly as a change of temperature of, say, 10° C., or a 1·15-fold dilution. It was found that even relatively mild flow conditions suffice to bring about complete reversal of phase separation in these systems.

The systems referred to are formed when two macromolecular solutes, for example, polystyrene and ethyl cellulose, are dissolved in the same solvent, for example, benzene. In such cases phase separation sets in at very low solute concentrations and the two phases formed contain disproportionate amounts of the two solutes. A comprehensive study of such systems has been made in particular by Dobry and Boyer-Kawenoki[1]. Taking as example the system polystyrene – ethyl cellulose – benzene used in our experiments, it is found that a solution containing only 2–3 per cent total polymer (degree of polymerization about 1,000) is separated into two phases at room temperature. These phases again each contain 97–98 per cent benzene, but one is largely a solution of polystyrene with only a little ethyl cellulose, and the other is an ethyl cellulose solution with relatively little polystyrene.

The two phases obtained in this manner are similar in their behaviour to the phases obtained when two partially miscible liquids, for example, water and amyl alcohol, are mixed together.

The systems are dependent on temperature and, in the particular case of the system polystyrene – ethyl cellulose – benzene considered here, the mutual solubility of the phases is increased as the temperature is raised. More ethyl cellulose is dissolved by the phase rich in polystyrene and more polystyrene by the phase rich in ethyl cellulose. The compositions of the two phases of the unstirred system therefore approach each other as the temperature is increased, and for each given overall composition there exists a well-defined 'critical' solution temperature T_c at which phase separation just ceases and above which the system is homogeneous.

Overall concentration (% w/w)			T_c (°C.)	Relative volume of phases at 21·7° C. i.e., T_c–10° C. (vol. %)	
Benzene	Polystyrene	Ethyl cellulose		I	II
97·1	1 14	1·80	31·7	47	53

At 22° C. the above system is obviously 10° C. below its critical temperature and is separated into two phases. If, however, a velocity gradient of $q = 200$ sec.$^{-1}$ is maintained in this system (at 22° C.) a homogeneous one-phase solution results. Ther exists, in fact, a quantitative relationship betwee the number of degrees, ΔT (°C.), by which the syste is below its critical solution temperature, and th rate of shear q (sec.$^{-1}$) which can completely rever the phase separation at the temperature $T_c - \Delta T$. I the case of the particular system investigated by u this is:

$$q = 20\ \Delta T. \qquad (1$$

In order to illustrate the rates of shear necessar according to (1) to produce a noticeable shift in th critical solution temperature, consider a Couett apparatus, that is, a cylindrical drum (say, 5 cm. i diameter), rotating in a concentric cup (say 7 cm. i internal diameter), the interspace being filled wit solution, and assume that the angular speed of rotatio of the drum is 1 revolution per second. (These pa ticular dimensions apply to the apparatus used by u It is worth noting, by the way, that, as the viscosit of the solution is 0·11 poise, laminar flow condition prevail up to about $q = 270$ sec.$^{-1}$.) Such a spee which could easily be maintained by hand, would i this case correspond to a rate of shear $q = 27$ sec. and would, according to (1), suffice to change th critical solution temperature by 1·3° C.

The changes observed in this manner are completely reversible, that is, the system separates aga (becomes turbid) as soon as the rate of shear drop below the values given by (1). The effect of the fiel of flow is thus to make the homogeneous syste stable at temperatures at which the homogeneou system of the same composition, but at rest, is metastable. This means that the free energy of the stirre homogeneous system, and with it also the free energ of certain of its components, must be larger than th corresponding quantities of the resting, separate system at the same temperature.

The reversal of phase separation in a field of flo is intimately connected with the large interfacial are which is created when the separated system is gentl stirred. An immediate break-up into fine drops take place, their final size being determined by the hydrodynamics of flow. By simple dimensional analys the mean linear dimension r of the largest dro which can exist in a laminar field of flow of velocit gradient q can be related to the interfacial tension and the viscosity η of the surrounding medium. W find:

$$r = \text{const.}\ \frac{\sigma}{\eta q}, \qquad (2$$

where the constant of proportionality is dimensionless and of the order of 0·15 in cases where th difference between the viscosity of the drop and th viscosity η of the surrounding medium is small[2].

If it is assumed that the interfacial tension is lef unaffected by the decrease in drop radius, equatio (2) represents the effect of the field of flow on dro size for all values of q. Our experiments have show that this is true only initially, that is, at low rate of shear, and only up to drop sizes of about 10^{-4} cm Further decrease in drop size is found to result in rapid decrease of interfacial tension and a complet reversal of the phase separation.

Experimentally, we infer the disappearance of th second phase from the disappearance of turbidity that is, of optical inhomogeneity in the system. I this optical homogeneity had been produced accordin to (2), that is, by a mere reduction in size of drop the necessary rate of shear would, obviously, hav had to be 1,000 times greater than that required fo

= 10^{-2} cm. Experimentally, however, we find a ctor of only about 10, clearly showing, as stated, at a breakdown of σ must have occurred at some termediate size of drop.

Theoretically, we can explain this phenomenon as llows. The interface between two phases is not finitely thin, but represents a transition zone of homogeneous composition, of finite thickness and lume. If this thickness is ε cm. and if there are sq. cm. of interfacial area per 1 c.c. of the system, en the interface occupies a fraction $f\varepsilon$ of the tal volume. The interfacial tension may be defined the free energy necessary to form ε c.c. of 'interce' out of the non-interfacial region of the system. he existence of f sq. cm. of interface therefore aplies a free energy increase of $f\sigma$ ergs/c.c. relative the state of the system in which $f = 0$. An isoermal approach in composition of the two phases ould reduce σ, and therefore $f\sigma$, but would at the me time increase the free energy in the $(1 - f\varepsilon)$ c.c. ot occupied by the interface. So long as f is small $\varepsilon \ll 1$), the change in composition, which must company a reduction in $f\sigma$, will therefore severely strict this effect. In our case, ε is determined by e dimensions of the coiled polymer in solution and , thus, of the order 10^{-6} cm. When the size of drop is therefore smaller than about 10^{-6} cm., the intercial volume, $f\varepsilon$, becomes comparable with 1, and an pproach in composition leading to a reduction in tal free energy, as well as in $f\sigma$, becomes possible. t constant rate of shear, q, this decrease in σ brings ith it, as secondary effect, a further reduction in ze of drop (see (2)), and, due to the increased value f f, a renewed change in composition. Equilibrium reached between these tendencies at lower rates of ear, but there exists a critical value of q at which ese effects so reinforce each other that there is a mplete resolution of all differences in composition nd a complete reversal of the phase separation.

In the above, we have given a somewhat simplified escription. Thus, at constant q and σ, there can be reduction in f, and therefore of $f\sigma$, by a solution of me of the dispersed phase in the surrounding edium (analogous to the increase of vapour pressure f small droplets by capillarity). This reduction in f , however, in our case, where dispersed phase and rrounding medium are of roughly equal volume, ccompanied by a correspondingly large change in mposition. The two effects, the one mentioned ow and that discussed in the preceding paragraph, re therefore on closer inspection seen to be nonseparable phenomena.

It is clear that, as the size of drop, r, becomes mparable with ε, the definition of r, and with the concept of capillarity, rapidly lose precision. he homogenization process at this stage may e pictured as a gradual replacement of the nonterfacial $(1-f\varepsilon)$-regions by the interfacial $(f\varepsilon)$-gions of the system (the interface will, in general, onsume' one phase faster than the other). As $\to 1$, the concentration gradient in the interface, r energetic reasons, tends to decrease, leading ventually to the homogeneous solution as the most able state. The use of f and σ has here only a ymbolic significance.

We have emphasized the fact that the homogeneous ystem has a larger free energy than the separated, nstirred system at the same temperature (as revealed y spontaneous demixing as soon as stirring is topped[2]). The otherwise unstable homogeneous tate is thus maintained at the expense of a continuous degradation of mechanical into thermal energy in the field of flow. The rate at which thermal energy is produced under the conditions described by equation (1) in a medium of viscosity $\eta = 0{\cdot}11$ poise is obviously $\eta q^2 = 44(\Delta T)^2$ erg/c.c. sec. On the other hand, the time during which a noticeable demixtion would take place in the solution is roughly equivalent to the time, t, taken by the coiled polymer to diffuse a distance, of the order of its end-to-end distance ($\sim 5 \times 10^{-6}$ cm.). Remembering that the diffusion constant of the polymer in a medium of this viscosity is about 10^{-8} cm.^{2}/sec., $t = \frac{1}{2}(5 \times 10^{-6})^2/10^{-8} = 1{\cdot}25 \times 10^{-3}$ sec. and the thermal energy produced in this time equals $5 \times 10^{-2}(\Delta T)^2$ erg/c.c. This we compare with the free energy required to homogenize 1 c.c. of the demixed system when it is ΔT° below T_c. Using the theory of Scott[1], it is easily shown that this energy is of the same magnitude, being in the present case about $6{\cdot}2 \times 10^{-2}(\Delta T)^2$ erg/c.c. The rate at which thermal energy is produced from mechanical energy in the field of flow is thus, indeed, sufficient to prevent the homogeneous system from demixing.

From the above it becomes clear that the effects observed (shift in solubility and critical solution temperature) need not be specific to systems with macromolecular components, although it can be seen why they are particularly large in such cases. Fundamentally the same situation arises in all liquid–liquid equilibria as well as in the case of liquid–vapour transitions and the corresponding critical phenomena. [Dec. 6.

INFLUENCE OF SUBSTITUENTS ON THE MESOMORPHISM OF *p*-*n*-ALKOXYBENZOIC AND 6-*n*-ALKOXY-2-NAPHTHOIC ACIDS

By G. W. GRAY and PROF. BRYNMOR JONES
University College, Hull

SINCE Reinhitzer's discovery of mesomorphism in 1888, a large number of organic compounds which show this phenomenon have been prepared. Their physical appearance and the texture of their mesophases have been extensively studied by Friedel and others; but there is at present little or no information concerning the molecular dimensions which determine whether a system will show mesomorphism, or of the effect of substituents on the range and character of the mesophases. Vorländer[1] discussed the significance of certain structural features, and Bernal and Crowfoot[2] attempted to indicate the types of structure which would lead to the formation of nematic and smectic phases. Weygand *et al.*[3] made a systematic study of certain homologous series of alkoxyanils, azo- and azoxy-compounds. Nevertheless, all that can be said is that to show mesomorphism an organic molecule must either be predominantly one-dimensional or rod-shaped, as in *p*-azoxyanisole, or saucer-shaped, as in the cholesteryl esters, thus allowing the close packing in both the crystalline and mesomorphic states. In no series, hitherto, has the influence of substituents been systematically studied.

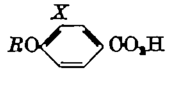
Table 1

	First appearance of: (a) nematic phase	(b) smectic phase	Smectic phase only	Maximum phase-length
X = H	$R = C_3H_7$	C_7H_{15}	$R = C_{18}H_{37}$	57° ($R = C_{10}H_{21}$)
F	C_8H_{17}	C_9H_{19}	$C_{16}H_{33}$	16° ($R = C_{16}H_{33}$)
Cl	C_8H_{17}	C_8H_{17}		4 5° ($R = C_{16}H_{33}$)

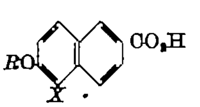
Table 2

	First appearance of: (a) nematic phase	(b) smectic phase	Smectic phase only	Maximum phase $R < C_{16}H_{33}$
X = Cl	$R = C_3H_7$	$R = C_6H_{13}$	$R = C_{16}H_{33}$ and $C_{18}H_{37}$	42° ($R = C_6H_{13}$)
Br	C_3H_7	C_7H_{15}	$C_{16}H_{33}$ and $C_{18}H_{37}$	40° ($R = C_7H_{15}$)
I	C_4H_9	C_8H_{17}	$C_{16}H_{33}$ and $C_{18}H_{37}$	25° ($R = C_8H_{17}$)
NO_2	C_9H_{19}	$C_{12}H_{25}$		1·5° ($R = C_{10}H_{21}$)

In an attempt to enlarge existing knowledge regarding the molecular dimensions which would appear to be necessary for mesomorphism to occur, an examination was recently made of the relative importance of length to breadth, or flat-area, in such molecules as the 4 : 1-, 5 : 1-, 6 : 2- and 7 : 2-*n*-alkoxynaphthoic acids[4]. Here, only the 6-*n*-alkoxy-2-naphthoic acids are mesomorphic. This investigation has now been followed by a study of the influence of substituents, particularly of the halogens, in the 3-position of *p*-*n*-alkoxybenzoic acids and in the 5-position of 6-*n*-alkoxy-2-naphthoic acids.



(I)



(II)

In the benzoic acids the effect of substituents is very marked. Introduction of the large bromine atom eliminates the mesomorphism completely. With chlorine and fluorine the mesophases persist, but their length is reduced, and their appearance in the series delayed. Thus, even with a fluorine atom, the nematic phase, which first appears in the unsubstituted acids in *p*-*n*-propoxybenzoic acid, is not found until the hydrocarbon chain is lengthened to octyl, in 3-fluoro-4-*n*-octyloxybenzoic acid. Moreover, in the unsubstituted acids a maximum phase-length of 57° is found in *p*-*n*-decyloxybenzoic acid[5,6]. In the fluoro-substituted acid the maximum phase-length is reduced to 16°, and in the chloro-acids it is only 4·5°. Both maxima are found in the *n*-cetyloxybenzoic acids. Some of the data are summarized in Table 1; the alkyl groups used were CH_3 to $C_{10}H_{21}$, $C_{12}H_{25}$, $C_{16}H_{33}$ and $C_{18}H_{37}$.

In view of these results, the absence of mesomorphism in 3 : 5-dichloro-4-*n*-alkoxy- and in 3-nitro-4-*n*-alkoxy- benzoic acids is not surprising.

A substituent in the alkoxynaphthoic acid (type II) affects its breadth (looked at along the line of axis of the O*R* and COOH groups) less than it does in the benzoic acid; even with a chlorine atom in the 5-position, the molecule is only a little broader than the parent acid. As a result, the decrease in the mesomorphism is far less marked than in the benzoic acids and, in all but the first members, mesomorphism persists throughout the chloro-, bromo- and iodo-alkoxynaphthoic acids. The influence of a nitro-group is much more striking, since its size and its polar character will probably affect orientation in the melt. The first eight acids in this series show no mesomorphism, but a short nematic phase appears in 5-nitro-6-*n*-nonyloxy-2-naphthoic acid. By contrast, a nematic phase is found in the unsubstitute 6-alkoxy-2-naphthoic acids in the 6-methoxy-aci and the maximum phase-length in the first twel members is 49° in 6-*n*-hexyloxy-2-naphthoic aci The influence of increasing group size on the mesomorphism is shown in Table 2.

A particularly interesting feature of these resul is the appearance of the smectic phase. In t chloro-acids, it emerges when *R* is hexyl, wi bromine as substituent when *R* is heptyl, and wi iodine when *R* is octyl. Thus, as the size of t halogen atom increases, this phase appears pr gressively later in the series.

It might have been expected that the appearan of the nematic phase would be affected similarl That is, since a nematic phase is found with iodi and bromine as substituents in the butoxy- an propoxy- acids respectively, it might be found in t chloro-series in the ethoxy-acid. Actually, t lengths of the phases in 5-bromo-6-*n*-propoxy- naphthoic acid and in 5-iodo-6-*n*-butoxy-2-naphtho acid are so short that they cannot be measured b normal methods (they persist for less than 0·1° Moreover, the melting points of the ethoxynaphtho acids are much higher than those of the propox acids, and it is therefore not surprising that so sho a phase is not found in 5-chloro-6-ethoxy-2-naphtho acid with its high melting point of 264°.

When the alkyl group contains twelve or mo carbon atoms, the effect of an increase in the size the substituent, particularly of the halogen, is not marked, and the halogeno-stearyloxynaphthoic aci become identical in their mesomorphic behaviour.

Table 3

	Phase-length			
	X = Cl	Br	I	NO_2
$R = C_{12}H_{25}$	35°	31°	24°	4°
$C_{16}H_{33}$	35°	34°	31°	4·5°
$C_{18}H_{37}$	35°	35°	35°	8°

These compounds are the first extended series substituted mesomorphic substances to be examin in detail. The gradual decrease in mesomorphism the naphthoic acids as the size of the substituent increased, together with its elimination in the benz acids, are noteworthy.

A fuller account of this work will be publish later. [Feb. 21.

E Region during the Solar Eclipse of February 25, 1952

During an eclipse of the sun, changes in the electron density (N) in an ionospheric layer of Chapman type may be represented by the relation:

$$\frac{dN}{dt} = q - \alpha' N^2, \qquad (1)$$

in which q is rate of production of electrons and α' is effective recombination coefficient. If the ionizing radiation were emitted uniformly from all parts of the disk, q would be proportional to the fraction (A_s) of the disk unobscured by the moon. Observations made at optical frequencies show that the disk radiation is not uniformly distributed. Consequently, if we assume that the ionizing radiation has a similar distribution, it is necessary to represent q during an eclipse by two terms denoting the intensity of the radiation coming from the uniform ($A_s I_0$) and non-uniform (I_s) components respectively. Thus:

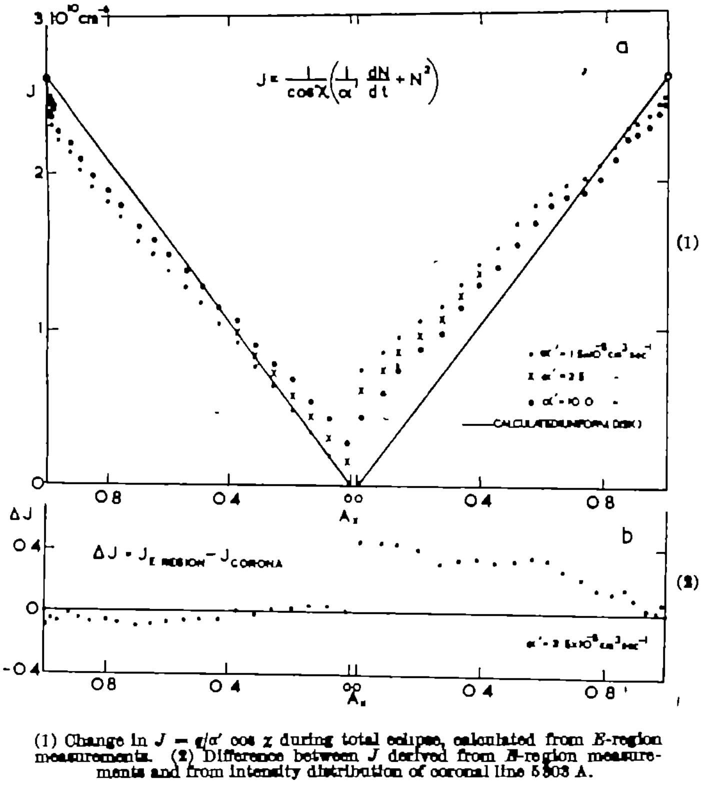
$$q = K \cos\chi \, (A_s I_0 + I_s), \qquad (2)$$

where K is a constant and χ is zenith angle of sun. Substituting this in equation (1), we can write:

$$\frac{K}{\alpha'}\,[A_s I_0 + I_s] = \frac{1}{\cos\chi}\left[\frac{1}{\alpha'}\frac{dN}{dt} + N^2\right] \; (= J). \qquad (3)$$

On the right, $\cos\chi$ is known, and N and dN/dt can be deduced from the changes in E-region critical frequency (foE) during the eclipse. Hence the values of J calculated from ionospheric measurements can be compared with those obtained by inserting different values of I_0 and I_s in the left of equation (3).

Measurements of foE were made at intervals of four minutes at Khartoum during the total solar eclipse of February 25, 1952. The standard deviation of the error in measuring foE was about 0·01 Mc./s. and, since special precautions were taken to ensure accurate timing, the maximum error in calculating dN/dt is probably about ± 10 per cent. J has been computed for several values of α', and the experimental points are shown in Fig. 1 with the computed values for a uniformly radiating disk. J has been plotted as a function of A_s since the slope of the line through the points is then proportional to I_0 (equation 3).



(1) Change in $J = q/\alpha' \cos\chi$ during total eclipse, calculated from E-region measurements. (2) Difference between J derived from E-region measurements and from intensity distribution of coronal line 5303 A.

The observations imply that the uniform (J_0) and non-uniform (J_s) components have magnitudes: $J_0 = 200 \times 10^8$ cm.$^{-3}$; $J_s = 60 \times 10^8$ cm.$^{-3}$. Part of the non-uniform component is divided about equally between the east and west limbs of the sun, since a sharp fall in J occurred just after first contact and a similar rise preceded fourth contact. It also seems probable that J did not fall to zero during totality.

These conclusions are consistent with the distribution of intensity over the disk of the green coronal line, information on which has been obtained through the courtesy of M. L. d'Azambuja, of the Paris Observatory at Meudon. The difference between the value of J calculated from the coronal data, assuming an extension to 1·04 solar diameters, and from the E-region measurements, assuming $\alpha' = 2·5 \times 10^{-8}$ cm.^{3} sec.$^{-1}$, is shown in Fig. 2. The main discrepancy appears abruptly just after totality, and suggests the existence of an intense source of ionizing radiation near the west limb of the sun which cannot be accounted for in terms of the solar data available at present. If J is not allowed to become negative just before totality, the minimum possible value of α' is $1·5 \times 10^{-8}$ cm.^{3} sec.$^{-1}$. This would imply that J rose from 0 just before, to 73 ± 10^8 cm.$^{-3}$ just after, totality, and also that 28 per cent of all the ionizing radiation was emitted from 0·4 per cent of the disk area. On these grounds a somewhat higher value of α' may be required, at least near totality.

A fuller account of these and other ionospheric measurements made during the eclipse will appear elsewhere. The work described above was carried out as part of the programme of the Radio Research Board and this note is published by permission of the Department of Scientific and Industrial Research.

Observation of a τ-Meson

ANOTHER example[1-4] of a τ-meson has been found, on an Ilford *G5* plate, 1,200 microns thick, exposed on Mount Rosa (4,550 m. above sea-level) surrounded by an aluminium absorber 5 cm. thick.

The τ-particle enters the emulsion from the glass almost horizontally, and, after travelling for about 8,000 microns, decays at rest into three particles, with tracks *a*, *b* and *c* (see photograph). The first two of these go into the glass after 2,600 and 2,000 microns in the emulsion respectively; the third, *c*, is much shorter and goes into the air after 100 microns.

The three tracks, *a*, *b*, *c*, are sufficiently long to allow accurate measurements of the projected angles between them and of their dips. We find the following: dip of *a* = − 29°; dip of *b* = − 36°; dip of *c* = + 49°; angle *ab* = 115° 30′; angle *ac* = 114° 30′. With these values one can verify that the three tracks are coplanar within ± 1° and lie in a plane inclined about 51° to the plane of the emulsion. The true angles are: angle *ab* = 91½°; angle *ac* = 127°.

Accurate measurements by grain counting have been carried out on the first two tracks, *a* and *b*, and less accurate ones on the third, *c*. The values obtained are: 68·5 ± 1·9, 49 ± 1·8, and 37 ± 4·3 grains per 100 microns respectively. These values have been referred to the ionization versus range relation experimentally determined for μ-mesons of the same part of the plate. In this way, we have found that the number of grains of the three tracks, *a*, *b*, *c*, are the same as those of μ-mesons at distances of 4·8 mm., 10·3 mm. and 17·5 mm. from the end of their range. If we suppose that the three tracks are due to π-mesons, we obtain in this way for their energies the following values: for *a*, 17·4 ± 0·7 MeV.; for *b*, 27·3 ± 1·2 MeV.; and for *c*, 37 ± 5 MeV. The independent measurements of the mean angle of scattering for the first two tracks *a* and *b*, which give $\bar{\alpha}_a$ = 0·98° ± 0·16° and $\bar{\alpha}_b$ = 0·47° ± 0·18°, are fairly consistent with the previous assumption.

Assuming that the total momentum of the three particles is zero, and that all three of them are π-mesons, one can easily calculate with the preceding data the mass of the τ-meson. Giving most weight to the grain-counting measurements, and assuming alternatively as exact the determinations relating to track *a* or to track *b*, we obtain the following results:

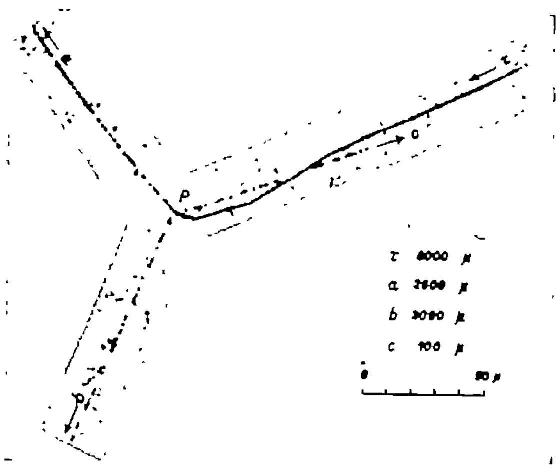
KINETIC ENERGY IN MEV

	Track *a*	Track *b*	Track *c*	Total	Mass of the τ-particle
Based on *a*	17·4 ± 0·7	28 2	43·3	87·9 ± 6·8	994·1 m_e
Based on *b*	16·8	27·3 ± 1·2	41	85·1 ± 7·2	968·6 m_e
Mean	17·1	27·8	41·6	86·5 ± 5	991 ± 15 m_e

In estimating the probable error, we have taken into account not only the errors in the grain counting and the measurement of the angles but also the lack of precision on the value of the thickness of the emulsion and the errors in the mass of the π-meson (274 ± 2 m_e).

The great length of the track of the τ-meson itself in the emulsion allows us to make two direct and independent measurements of its mass, based on the angle of scattering and range and on the ionization and range relations.

For the first, we have divided the track in parts of 1 mm. and have measured the angle of scattering for each of them, and hence the energy (for a low-energy



track one can obtain directly the energy from the *p* value without knowing the mass). The energ versus range relation is found to be:

Range	500	1,500	2,500	3,500	4,500	5,500	6,500	micron
Energy	7·8	13 1	16·3	21	24 2	27·6	32	MeV.

The corresponding mass of the particle is 946 ± 140 m_e

For the second, the gap/range relation for th τ-particle has been plotted and compared with gap range relations for protons and μ-mesons; in thi way a value for the mass of 995 ± 150 m_e has been found. As a mean value from the two direct measure ments we can take 970 ± 100 m_e, in fair agreemen with the preceding determination.

The accuracy in the determination of the data o two of the disintegration tracks, *a* and *b*, enable us to test, by means of the conservation of momen tum, whether the event considered can be inter preted satisfactorily only by assuming that the three disintegration tracks are due to π-mesons, or whethe alternative modes of decay, including one or more μ-mesons, are possible. We have therefore calculated assuming as exact the experimental values of th energy relating to track *a*, the values of the energy for the other two tracks in accordance with th conservation of momentum, in all the possibl cases. We obtain in this way the following eight possibilities:

KINETIC ENERGY IN MEV.

a	*b*		E_a	E_b theoretical	E_c theoretical	E_b experimental	E_c experimental
π	π	π	17 1	27 8	41·6	27·3	37
π	π	μ	17·1	27 8	49·7	27·3	28·9
π	μ	π	17·1	33·7	41 6	21·3	37
π	μ	μ	17 1	33·7	49·7	21·3	28 9
μ	π	π	13 6	17·8	27·0	27·3	37
μ	π	μ	13 6	17·8	33 5	27·3	28 9
μ	μ	π	13·6	22·5	27 0	21·3	37
μ	μ	μ	13 6	22·5	33·5	21·3	28·9

We see that the only cases in which there is complete agreement for the three tracks between theoretical and experimental values within the experimental errors are the first and the last; that is, either if the three tracks are all π-mesons, or if they are all μ-mesons. But in this last case the total energy of the three tracks would be 63·8 MeV., and that would give for the mass of the τ-meson the value 766 m_e, which is well outside the probable error of the direct determination of mass of 970 ± 100 m_e. We think, therefore, that our analysis gives direct evidence that the three decay products of the τ-meson are all π-mesons, even without reference to preceding similar events, in which the nuclear interaction[1] or the direct measurement[4] of the mass of one of the condaries has already given evidence that at least ne of them was a π-meson.

It is interesting to observe that our detailed analysis f the event was made possible by the fact that it ok place in a very thick emulsion; for the great clination of the plane of the π-mesons to the plane f the emulsion would not otherwise have allowed e tracks to be sufficiently long for that purpose.

We wish to acknowledge the help of the Brussels roup and especially of Prof. G. Occhialini in developg the plate. The event was discovered by Mr. M. reco.

Detection of *S* Waves in the Earth's Inner Core

A theoretical calculation by one of us[1] shows at, if the earth's inner core has a rigidity comparable ith its incompressibility, then the seismic phase KJKP would, on present available knowledge, be ost likely to be detected over a range of epicentral stance Δ given by 130° $\leqslant$ Δ $\leqslant$ 155°, the expected ergy and amplitude in this phase being about 0·04 d 0·2, respectively, of that in the companion phase KIKP. The phase *PKJKP* appears, therefore, to on the border of observability and, if the solidity the inner core is to be established, it becomes portant to investigate the practical question of tecting a phase of such low amplitude.

The difficulty of the process of detection has been arply focused by work of one of us (T. N. B.-G.), ho has searched for the phase *PKJKP* over the ries of seismograms recorded at the Riverview ollege Observatory from 1909 to the present day. he work, details of which are to be published elsehere, shows that, of the whole series, there were ly seventeen shocks for which Δ was in the above nge and for which the amplitude of *P′* was greater an or equal to 4 μ. Of these seventeen shocks, Δ was proximately in the range 142°–145° in ten cases, and ere was a fair probability that the observed *P′* reted to a branch other than *PKIKP*. Of the remaing seven shocks, one had *P′* amplitudes of 6 μ, two of μ and four of 4 μ. In the case of *P′* amplitude 6 μ Δ = 133°), there were microseisms of amplitude near the theoretical arrival-time of *PKJKP* and impulse was observed. In one of the cases of *P′* plitude 5 μ, microseisms were significant, and in the her the seismogram was changed at the expected KJKP arrival-time. In the cases of *P′* amplitude , there were movements near the expected arrivale of *PKJKP* of amplitudes greater than or equal those of *P′*; the size of these amplitudes means at they must be attributed to other causes.

The "International Seismological Summary" is of nited value in the search for *PKJKP* as it does not cord amplitudes. A search was made over a section the "Summary", and, while a limited number of recorded impulses were found to agree with the travel-time of *PKJKP*, it was not possible statistically to make any inference.

The main point which emerges from this investigation is the relatively small number of records from which the existence of the phase *PKJKP* is likely to be substantiated. It appears that, unless a record is traced far inland where microseisms are negligible, a prerequisite for observation of *PKJKP* is that the *PKIKP* amplitude should be at least about 20 μ. Not one of the Riverview seismograms over a period of more than forty years both conforms to this criterion and has the value of Δ in the correct range. The important question as to whether the earth's inner core is solid can therefore not be decided in this way, unless many routine observatory workers would be willing to record significant onsets (preferably on vertical component seismograms) within 20–30 sec. (say) on either side of the expected arrival-time[2] of *PKJKP*, whenever the *PKIKP* amplitude reaches 20 μ. The first of the signatories to this letter would appreciate it if details of such recordings could be transmitted to him. It appears that the best ranges to consider are 130° $\leqslant$ Δ < 142°, 145° < Δ $\leqslant$ 155° (for 142° $\leqslant$ Δ $\leqslant$ 145°, it is difficult to estimate the amplitude of *PKIKP*).

It may be remarked that in the large earthquake of November 25, 1941 (φ = 37·5° N., λ = 18·5° W.), the *P′* amplitude at Riverview was 74 μ, while amplitudes of 11 μ and 15 μ were recorded on the vertical component, respectively 2 sec. before and 11 sec. after the expected arrival-time of *PKJKP*. The value of Δ for this earthquake is 171°, for which the calculated amplitude of *PKJKP* is only 0·03 times that of *PKIKP*. The theoretical amplitude calculations could be in appreciable error if the region *F* of the earth[3] differs seriously from the simple model assumed in the calculations, so that the onsets recorded at Riverview in the case of this earthquake could just possibly be significant in relation to *PKJKP*. It is suggested that the records of this earthquake might well be examined at observatories within the ranges of distance mentioned in the previous paragraph.

Silver Films and Dielectric Multiple Films in Interferometry

The work on multi-layer dielectric films as described recently by A. H. Jarrett and H. v. Klüber[1] is of interest in two respects: the reflectivities reported are rather higher than those found by other workers, and the successful use with étalons shows that these films must have a considerable degree of uniformity. But the comparison of the relative merits of these films and silver films for use with Fabry–Perot interferometers is very misleading. Jarrett and v. Kluber do not mention recent publications on the resolving power of silvered étalons and the reflectivity of evaporated silver layers[2]. If the measurements published in these papers are taken into account, it is apparent that multilayer coatings are not superior, in the range of wave-lengths over which they have been investigated, to evaporated silver films of good quality.

The value $R = 0{\cdot}90$ does not represent the "useful upper limit" of the reflectivity of silver layers (as is stated by Jarrett). The direct measurements made with new layers by Kuhn and Wilson show that, for a transmissivity of 0·02, the reflectivity varies from 0·97 to 0·96, and the absorption from 0·01 to 0·02 over the range of wave-lengths from 6800 to 5200 A. The performance of these silver layers is thus slightly superior to that of Jarrett's multilayer coating, which was found to have a reflectivity of 0·97 and an absorption of 0·02 in this region. The reflectivity and absorption of silver films three weeks old are about the same as for multilayer films. Towards shorter wave-lengths the efficiency of both silver and dielectric films decreases, but not enough quantitative data for the latter are available to allow comparison.

In practice, very high reflectivities are not used with étalons, since the limiting factor to the resolving power is the accuracy of working of the surfaces of the plates. With plates of good quality, the errors are not substantially smaller than 1/50 fringe; and since a reflectivity of 0·95 produces fringes with a width of 1/60 of an order, there is little to be gained by using layers denser than that required to produce this reflectivity. The width of the fringes of the line 5436 is estimated by v. Kluber to be 1/34 order, equivalent to a reflectivity of 0·91. The measured width of fringes produced with silver layers was 1/39 order, for films with a transmissivity of 0·04. These fringes were thus narrower than those produced by the multilayer coating, but in both instances the fringe-width was probably substantially increased by imperfection in the surfacing of the plates.

Judged on the basis of existing experimental data, multilayer films offer the advantage of a very slight gain in intensity in the range of lower reflectivities, below about 0·9. This should make them useful as étalon coatings for special purposes; if they could be made to operate for violet and ultra-violet light, they might gain considerable importance in spectroscopic interferometry.

[1] *Nature*, 169, 790 (1952).

[2] Bright, R. J., Jackson, D. A., and Kuhn, H., *Proc. Phys. Soc.*, A, 62, 225 (1949). Kuhn, H., and Wilson, B. A., *Proc. Phys. Soc.*, B, 63, 745 (1950), and references given there.

The silver films reported by D. A. Jackson and K. Kuhn are very efficient; considerably more so than those quoted by previous workers[1].

In this connexion, I wish to state that I have recently produced silver films possessing a reflectivity of 94 per cent and an absorption coefficient as low as 0·03 for $\lambda = 5461$ A., so giving an efficiency similar to that recorded by Kuhn and Wilson[2] for an aged silver film at 5200 A. Extreme care was exercised with regard to the cleanliness of all the surfaces in the vacuum vessel.

From a graph in the same paper, for an aged silve film at 5200 A., one concludes that $R = 0{\cdot}97$ fo $T = 0{\cdot}005$, that is, $A = 0{\cdot}025$. These values ma be compared with those for the multilayer coating which were the subject of a previous communication[3]

Coating	R (per cent)	A (per cent)	T (per cent)	$\tau = \left(\frac{T}{T+A}\right)'$
Silver (fresh)	97	2·0	1·0	0·11
Silver (aged)	97	2·5	0·5	0·08
9-Layer dielectric	97	2·0	1·0	0·11
Silver (fresh)	94	2·0	4·0	0·44
Silver (aged)	94	3·0	3·0	0·25
7-Layer dielectric	94	1·0	5·0	0·69

(The figures for silver are from Kuhn and Wilson's results for 5200 A ref. 2.)

The multilayer coatings were measured during th two days following their production.

Since the underlying motive for pursuing the mult layer investigations was to obtain as large a tran parency (τ in the table) as possible for the étalo compatible with a small fringe half-width—a featu of supreme importance for phenomena, such as sol flares, etc., of limited duration—the conclusion fro the above is that the multilayer coatings possess th greater transparency for the lower reflectivity cited but for the higher value the freshly prepared silv films of Kuhn and Wilson appear their equal. must be stressed, however, that the multilayer cha acteristics were not obtained immediately aft deposition.

The comments in the foregoing corresponden appertaining to the possibilities of multilayer coatin for the blue end of the spectrum would depend suitable dielectrics being obtained exhibiting litt absorption in this region; zinc sulphide, for exampl has an absorption band[4] at 3650 A.

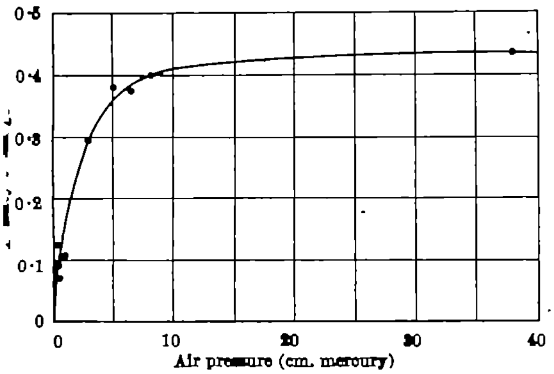
Russell Effect on Evaporated Metal Films

In 1897, Russell[1] discovered that freshly abrad metal surfaces produce an image on photograph plates and suggested that hydrogen peroxide responsible for this action. Although a conside able amount of work was done on this subject the first decade of this century, the only more rece publication is a paper by Churchill[2]. Work in t Mechanical Engineering Research Laboratories Thorntonhall confirms that hydrogen peroxide produced whenever fresh surfaces of certain met are exposed to the action of water and oxygen. Wh for example, aluminium, magnesium, nickel or zi is cut under water, measurable quantities of hydr gen peroxide are produced[3].

Recently, we have found that evaporated films metals, when exposed to the action of oxygen a water vapour, are capable of producing an image photographic plates. Before briefly describing t



xperimental procedure used, it is necessary to state at no satisfactory explanation of the cause of the ussell effect has so far been advanced. In our view, is caused by the availability of free electrons on eshly exposed metal surfaces, as recently described y Kramer[4]. The following reactions then lead to e formation of hydrogen peroxide :

$$e + H^+ \,{}^-OH \rightarrow H^\cdot \,{}^-OH \rightarrow H^\cdot + (:OH)^- \quad (1)$$

$$H^\cdot + O_2 \rightarrow HO^\cdot_2 \quad (2)$$

$$IO^\cdot_2 + H_2O \rightarrow H_2O_2 + {}^\cdot OH. \quad (3)$$

he hydroxyl radicals disappear either through

$$+ {}^\cdot OH \rightarrow (:OH)^- \;(4)\text{ or } 2.OH \xrightarrow{\text{third body}} H_2O_2. \;(5)$$

The experimental investigation of the Russell ffect with evaporated metal films was carried out the following manner. Using a conventional vaporator, metal was evaporated *in vacuo* on to a lass slide fixed on a small carriage. After evapora- on, and without breaking the vacuum, the carriage as allowed to slide into a light-tight box holding a oroughly outgassed Ilford 'half-tone' plate. Air ontaining a certain quantity of water vapour was dmitted to the evaporator. After 24 hr. the plate as removed and developed by a standard procedure. he optical density of the plate was measured by eans of a photometer.

The experimental results show that, at a given tio of water vapour to oxygen, the optical density creases at first with the increase in air pressure. t higher air pressures the density becomes independ- nt of the pressure. This is illustrated in the accom- anying graph, which shows the results obtained ith an evaporated film of aluminium, using air ntaining 1·8 per cent by volume water vapour. Complete results of the investigation will be blished elsewhere.

Adaptive Mechanisms of Buffaloes to Ambient Temperature

Animals of diverse origin vary widely in their capacity to withstand severe climatic conditions. Breed differences in the response to high external temperatures and humidity were demonstrated by Rhoad[1]. Buffaloes have a lower level of respiration-rate, body-temperature and pulse-rate than cattle[2]. Under shade, they have a better cooling mechanism than cows, as has been shown in India[3]. The black-pigmented skin assists the absorption of infra-red rays with a subsequent rise in body-temperature[4], while in thin-skinned animals heat penetrates easily, resulting in over-heating of the body and interference with efficient elimination of heat[5]. Shedding of hair in cattle is a seasonal phenomenon[6].

Six non-pregnant buffalo cows (eight years old) were kept in open stable during 7–10 a.m., exposed to direct sunlight for two hours starting at 10 a.m., and then removed to shade until 2 p.m. Respiration-rate, body-temperature and pulse-rate were recorded every ten minutes at intervals from 7 to 8 a.m. and from 10 a.m. to 2 p.m. The fluctuation in the three items were measured and expressed as deviations from the normal deviation[7]. Atmospheric temperature (which ranged from 23·5° to 43·0° C.) and relative humidity (which ranged from 40 to 79 per cent) were recorded throughout the experiment. Shedding of hair, colour of hide, and thickness of skin (measured at shoulder) were carried out on fifty buffaloes.

No noticeable variations were observed in respiration-rate, body-temperature and pulse-rate between 7 and 8 a.m. in the shade. Soon after exposure to sunlight, both respiration-rate and body-temperature began to rise. The increase in pulse-rate during the first hour of exposure fluctuated. During the second hour of exposure, the respiration-rate increased to a smaller extent than during the first hour. The increase in both body-temperature and pulse-rate was nearly double the increase occurring during the first hour. When the animals were removed to shade, there was a sudden decline in respiration-rate. This decline occurred after a latent period, of ten minutes for body-temperature and forty minutes for pulse-rate. The percentage of increase in respiration-rate, body-temperature and pulse-rate during the two hours of exposure to sun was followed by a similar decrease at the end of the first hour of shade. The relative decrease in body-temperature was greater than in respiration-rate and pulse-rate during the second hour of shade.

Newly born buffalo calves have long dense hair of brownish steel-grey colour. As the animals grow older, the density of the hair becomes less. Shedding usually takes place at the age of three years. Pregnancy and lactation hasten shedding of hair. Shedding of hair occurs at the end of spring and at the beginning of summer months. The pigmentation of the buffalo skin varies from black to steel-grey. When the animals are kept in close confinement, the skin loses its pigmentation and becomes reddish-white. The pigmentation is regained after removal to direct sunlight. The skin of the buffalo is flexible and its thickness varies with age (see accompanying table). The brisket skin in the buffaloes is well developed,

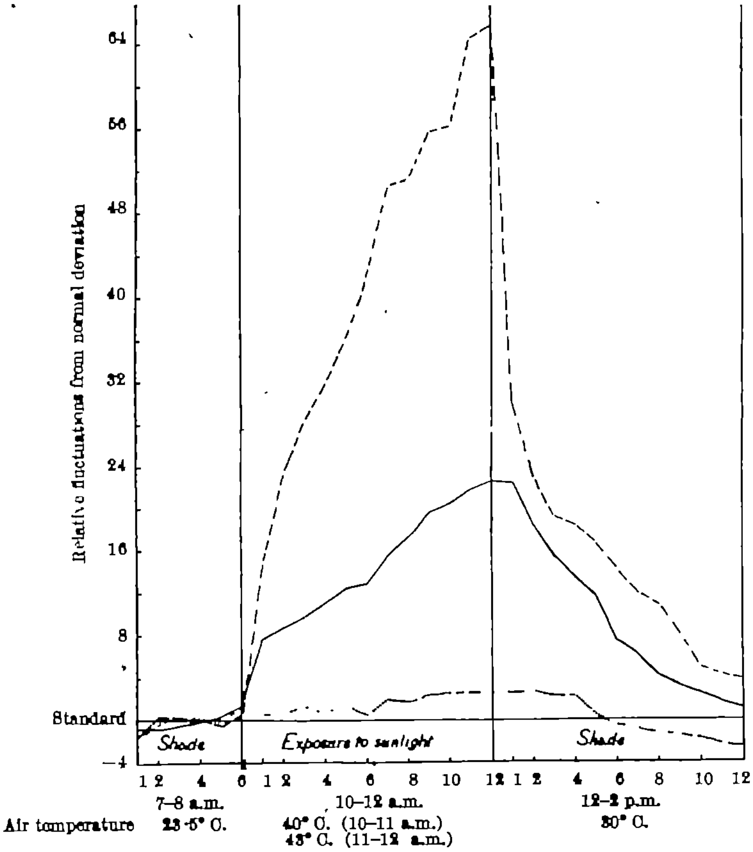
Thickness of buffalo skin (mm.)

Age	Calves	1–2 yr.	2–3 yr.	Mature
Skin thickness	4·47±0·4994	5·40±0·7849	5 48±0 1094	6 01 ± 1·447

and on exposure skin secretions are usually noticed between the fore-limbs as well as between the hind-limbs around the udder.

Respiration-rate in the buffalo increases on exposure to hot conditions whereas the rise in body-temperature is delayed. When removed from sunlight to shade, the respiration-rate was also first affected. It would seem that the respiratory tract is the first means of dissipating heat accumulated in the animals. As the respiratory movements cannot cope with the extra elimination of heat from the body, the pulse-rate is increased reflexly, but after a latent period. The increase in pulse-rate may be regarded as an attempt to stimulate the peripheral circulation and so helps heat loss through increasing salivation and skin secretions. Further investigation is needed to clear up the mechanism of peripheral circulation as affected by ambient heat. After one hour of shade, the buffaloes were able to lose almost all the heat gained at the time of exposure. The time required for eliminating extra heat through exposure needs investigation also.

The adaptive mechanism of the buffalo to hot humid climates is characteristic to the breed. The black-pigmented hide absorbs the infra-red rays of solar radiation and thus limits the animal's adaptability to exposure to sunlight. Such exposure does not occur under either wild or domesticated conditions. In the shade, however, the black coloration aids heat dissipation. The thick skin of the buffalo may prevent heating of the body from hot air and by radiation from the sun or hot ground. Hence we believe that although the buffalo is surviving in ho zones, where humidity is high, shade and coolin systems are needed for the animal's comfort.



----, Respiration-rate; ———, body temperature; . . . ., pulse-rate

Relative fluctuations of body-temperature, respiration-rate and pulse-rate of buffaloes in sun and shade, under normal (7–8 a.m.) and experimental (10 a.m.–2 p.m.) periods

This work, which is still in progress, has bee carried out at the Animal Breeding Research Station Cairo. Thanks are due to Mr. M. Ibrahim for statistical advice.

Photoperiodic Behaviour of *Hibiscus sabdariffa*, L.N.P.5

Hibiscus sabdariffa, L., is one of the most importan fibre plants of India, commonly known as rosell fibre. There are several well-known varieties[1]. Th plants can be grown on all types of soils, and henc the economic possibilities are considerable. study of photoperiodic effects was undertaken in Ma 1951, since the strain was found to grow best whe sown during May–June.

For a study of the photoperiod effects of the plant, seeds obtaine through the courtesy of the India Agricultural Research Institut New Delhi, were sown in earthen ware pots of 13-in. diameter in circle equidistant from the rim an the centre of the pot on May 2 By May 25, the cotyledons wer unfolded and the plants were read for treatment. There were fou plants per pot and three pots p treatment, so that twelve plan were taken for each treatmen Light periods ranged from eigh hours to sixteen hours; for ligh periods longer than normal, add itional illumination was provide from an electric bulb (100 candl power) at a distance of 1 m., whi for the shorter light periods th plants were taken inside a venti ated dark chamber for the required period before dusk and we brought back to the field aft nightfall.

The results are given in t accompanying table as the mean the readings for twelve plants p treatment. Flowering time denot the time taken for the initiation the first visible flower-bud, an fruiting time, the appearance of th first visible fruit. In addition, th total height of the plant an the circumference at the base the stem on the flowering day wer noted separately for each plant.

eatment	Mean height at flowering in cm.	Mean basal circumference of stem at flowering in cm.	Mean flowering time in days	Mean fruiting time in days
8 hr.	93·8	2 984	87·5	92
0 hr.	71·36	2 125	69 25	75
2 hr.	210·7	4 1	126	131
4 hr.	240 783	4 6	141	150
6 hr.	235·066	5 28	154	162
ontrol	236·7	5 0	122	127

he daily light period of the normal plants rose dually from 13 hr. 20 min. on May 25 to 13 hr. min. on June 22 and again fell gradually to 12 hr. nin. at the time of flowering.

t is evident that *H. sabdariffa*, *L.N.P.*5, has a y definite photoperiodic response and is a short- plant flowering fifty-three days earlier than the ntrol under the short-light period of 10 hr. At r., however, there is an average delay of nineteen ys from those at 10 hr. At longer photoperiods wering is delayed. The earliness of flowering is y marked at 10 hr. while a conspicuous delay urs among the 14- and 16-hr. groups. Bolhuis[2] ted and Ergle *et al.*[3] confirmed the fact that flower- in *H. sabdariffa* var. *altissima* is strongly influenced the length of day. The behaviour of *H. sabdariffa*, *N.P.*5, appears to be similar.

My thanks are due to Dr. J. C. Sen Gupta for his erest in the work.

Effects of Preliminary Treatment on the ubsequent Variation in the Resistance of *Lemna minor* to the Phytotoxic Action of 2 : 4 Dichlorophenoxyacetic Acid

DURING a study of the inter-relationships between ht intensity, temperature and the biological effects 2 : 4 dichlorophenoxyacetic acid, it was found in e case of *Lemna minor* (duckweed) that when the ncentration of the growth regulator in the external ater culture solution was sufficiently high to kill me of the fronds at the end of three days exposure, en the mortality increased with decreasing light tensity over the range of continuous illumination 0–180 ft. candles. It was further observed that, hereas the degree of toxicity was markedly depend- t on the light intensity received by the fronds prior treatment with the dichlorophenoxyacetic acid re-treatment period'), yet similar variations in the tensity during the following short 'treatment riod' of three days had no effect.

Since the ratio of area to weight was increased low levels of light, it was at first thought that this ger proportion of surface was associated with a eater uptake of the toxicant. However, as the oduct of the area–weight ratio and the concentra- on required to produce a 50 per cent mortality (the .D. 50' determined by probit analysis) was not onstant this explanation seems unlikely. Further- ore, when fronds in the pre-treatment period were eated with low and non-lethal concentrations of dichlorophenoxyacetic acid, although the area to weight ratio was little affected, the concentrations required to give a 50 per cent kill in the following treatment period were greatly increased. Thus, while without initial pre-treatment the required concentration of the acid was 81 p.p.m., it rose to 91, 116 and 193 p.p.m. after the fronds had been exposed respectively to 2·5, 10 and 40 p.p.m. in the previous twenty-four hours.

The next step was to determine whether this increased resistance induced by the pre-treatment was a specific effect. Accordingly, experiments were carried out in which fronds in the initial period were placed for twenty-four hours in low concentrations of a number of other compounds—for example, 2-methyl-4-chlorophenoxyacetic acid, 2 : 4 dinitro-*o*-cresol and cupric sulphate. In each case, such an initial treatment increased the resistance to dichlorophenoxyacetic acid in the treatment period. For example, pre-treatment with dinitro-*o*-cresol at 0·5 p.p.m. demanded a rise from 83 to 148 p.p.m. in the concentration of the phenoxyacetic acid needed to bring about the standard 50 per cent mortality.

When in the pre-treatment period the time of exposure to 40 p.p.m. dichlorophenoxyacetic acid was varied from 0·75 to 48 hours it was found that the induced increase in resistance to the *same* compound reached a maximum and steady value at the end of 3 hr., but that treatment for as little as 0·75 hr. had a significant effect. It is not possible to rule out enzyme adaptation as an explanation for the results of this experiment, since even within the short periods recorded many 'generations' of an enzyme may have taken place. However, on this basis, it is difficult to account for the common effect of different compounds on the subsequent response of *L. minor* to dichlorophenoxyacetic acid.

The results will be reported more fully and discussed in greater detail elsewhere. The techniques of the *Lemna* culture and the methods of probit analysis have been previously described[1-3].

Neurospora following a Volcanic Eruption

EARLY in 1951, Mount Lamington in New Guinea erupted violently, and the resulting shower of hot ashes which followed the explosion devastated many miles of the countryside, causing severe damage and loss of life. Very soon after the eruption, Mr. G. A. Taylor, volcanologist stationed in New Guinea, visited the area, and in the course of his investigations found large patches of a pink fungus which he collected and sent for identification. The fungus was readily isolated and proved to be a heterothallic species of *Neurospora*, which has been provisionally identified as *N. crassa* (Shear and Dodge). The genus *Neurospora* is well known as a troublesome pest of bakeries and similar high-temperature situations. The ascospores of this genus do not germinate readily unless subjected for a brief period to high temperatures (for example, 1 hr. at 60° C.). Its occurrence, therefore, in the Mount Lamington area, while not at all surprising to mycologists, is an interesting example of the invasion of an unusual ecological niche.

Occurrence of Putrescine in Potassium-deficient Barley

THE identification of primary effects of potassium in plant cells has proved to be one of the most elusive problems in mineral nutrition. Many widespread physiological disturbances accompanying potassium deficiency are well known, especially in the fields of nitrogen and carbohydrate metabolism; but the immediate causes of the characteristic (yet variable) leaf symptoms and the premature death of foliage have been almost entirely a matter for speculation. This communication is intended to direct attention to the fact that in barley, at least, putrescine is produced and accumulated under certain conditions of potassium deficiency, and that some of the observed symptoms may well be directly attributable to its presence.

A qualitative investigation, by means of paper chromatography, into the free ninhydrin-reacting compounds in barley leaves (F. J. Richards and E. Berner, in the press) revealed the frequent occurrence there of an unidentified basic substance. It was found in more than trace amounts only in potassium-deficient plants, and only in such of those as had not been supplied with either sodium or rubidium. Any of these alkali metals appeared to suppress its accumulation. Where it did occur it was present from an early age, increasing in quantity as the external symptoms of deficiency became acute.

In order to isolate and identify the substance, a large quantity of potassium-deficient barley was grown in 1951. Green laminæ, moribund leaves and stems from this material all contained the compound; indeed, on chromatograms from the moribund leaves it provided the most intense of all the ninhydrin spots. The substance was first isolated from the other ninhydrin-reacting compounds present in 75 per cent alcoholic extracts by elution on columns of 'Permutit' special sulphonated polystyrene resin; after passing hydrochloric acid and ammonium hydroxide through the charged columns the substance was removed by means of 0·2 *M* ammonium carbonate. The eluate was partially evaporated to remove the ammonia, acidified with hydrochloric acid and evaporated to dryness. The residue was then steam-distilled from a soda solution, acidified and evaporated nearly to dryness; a little ethanol was added and the substance thrown down with acetone. It was finally re-distilled and re-precipitated.

The isolated substance was indistinguishable from putrescine, whether in the form of hydrochloride, platinichloride or picrate; chromatographically, too, it behaved exactly like putrescine. The identification was confirmed by the production of identical X-ray powder photographs from the isolated substance and from putrescine hydrochloride; thanks are due to the Pedology Department of Rothamsted Experimental Station for taking these photographs.

The concentration of putrescine in the moribund potassium-deficient leaves is quite high, the yield indicating that the content of the free base mu have been at least 0·15–0·2 per cent dry weigh No estimate of the content in green leaves has y been made, but is, of course, lower than this.

Preliminary work involving feeding putresci through the partially cut leaves of high-potassiu plants has revealed toxic effects which bear clo resemblances to some of the symptoms found potassium-deficient barley. Chlorophyll disappea in patches and death soon follows. This may occ even on tillers remote from the one receiving t putrescine directly, distal parts of the leaves th being especially affected. The toxic sympton induced by the free base, however, differ somewh from those developed when the hydrochloride supplied.

It is hoped that experiments in progress may thr some light on the origin of the amine (ornithine wou seem to be the most likely precursor, but is n normally detectable in barley leaf extracts), a whether or not it is also produced, but metaboliz immediately, in the presence of alkali metals.

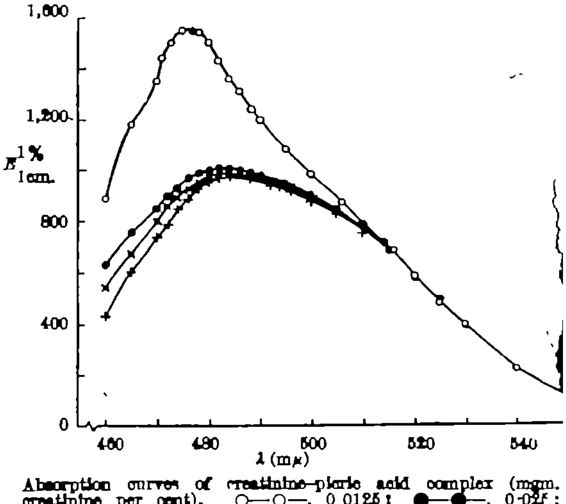
Determination of Creatinine

CREATININE is commonly determined in biologic fluids by various modifications of the Jaffe reactio The method is recognized as being non-specific an must be applied with caution unless there is a lar excess of creatinine present over interfering su stances. The specificity of the method has bee greatly improved by Miller and Dubos[1].

Peters[2] has pointed out that a significant deviatio from Beer's law becomes apparent at conce trations of creatinine greater than 5 mgm. p cent. This may be due to the bicolorimetric natu of the determination; the orange-red colour being mixture of the red of the coloured creatinine comple and the yellow of unchanged picric acid. So far as known, it has not been made clear that anomalie may also occur at low concentrations of creatinin

As the accompanying graph shows, it has bee found that if the absorption spectrum of the creatinir



Absorption curves of creatinine–picric acid complex (mgm. creatinine per cent). ○—○—, 0·0125; ●—●—, 0·025; ×—×—, 0·05; +—+—, 0·1 ıplex (against a picric acid compensator) is plotted lifferent concentrations of creatinine, not only does x vary, but so also does E(1 per cent, 1 cm.).

Iost clinical methods recommend that the colour duced in this reaction should be read using a -mμ filter. An explicit reason for this can now be en, for the absorption curves become closely vergent at a wave-length of about 515 mμ.

'he findings indicate that the reaction postulated Greenwald[3], in which one molecule of picric acid said to react with one molecule of creatinine to duce a tautomeric (enolic) form of creatinine rate, cannot be as simple as considered hitherto.

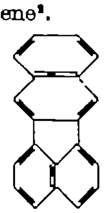
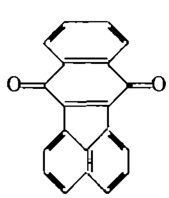
olation of 11 : 12-Benzfluoranthene from a Coal Tar Fraction

A RECENT description by Kruber and Oberkobusch[1] the isolation from a coal tar pitch fraction of an dentified hydrocarbon $C_{20}H_{12}$ (m.p. 216° C.) mpts me to record the isolation from a correspond- coal tar fraction of a hydrocarbon which possesses ilar properties and which has been identified as : 12-benzfluoranthene (I). The substance was ained from a fraction (b.p. 269–279° C./5 mm.) duced by high-efficiency fractionation of the tral portion of a distillate obtained during the duction of pitch coke. By crystallizing the soft nous fraction from ether, a yellow solid was ained which was purified by the crystallization l subsequent decomposition of its 1 : 3 : 5-tri- obenzene derivative. The pure hydrocarbon stallized from benzene as very pale yellow needles,). 216–217° C. It had a molecular formula of H_{12}, and its ultra-violet absorption spectrum was ntical with that published for 11 : 12-benzfluor- hene[2].



(I)



(II)

'he identity of the hydrocarbon was confirmed comparison with a synthetic specimen of 11 : 12- zfluoranthene prepared according to the method cribed by Orchin and Reggel[2]. The following vatives of the coal tar hydrocarbon were also ntical with the corresponding complexes formed n the synthetic hydrocarbon: unstable picrate d needles, m.p. 167–168° C.), 1 : 3 : 5-trinitro- nzene derivative (golden-yellow needles, m.p. –182° C.), 2 : 4 : 7-trinitrofluorenone derivative ange-red microcrystals, m.p. 253–254° C.).

xidation of both the synthetic and coal tar lrocarbons with potassium dichromate in acetic l yielded a quinone which, after purification by omatography on activated alumina, crystallized bright red needles, m.p. 236–237° C. Analytical ıres were in agreement with the formula $C_{20}H_{10}O_2$. rther oxidation produced naphthalic anhydride, indicating that the quinone has the structure (II), assigned to it by Moureu, Chovin and Rivoal[3].

A complete account of the investigation of the pitch-coking distillate will be published at a later date.

Sugar Components of Blood and Urinary Glycoproteins: Confirmation of the Presence of Fucose by a New Reaction

DURING the course of a systematic study of the carbohydrate constituents of some glycoproteins of human and animal origin, a number of unexpected component sugars have been separated by paper chromatography. In particular, the presence of fucose has been definitely demonstrated in human serum mucoprotein and in normal human urinary proteins.

Serum mucoprotein was prepared by the method of Weumer *et al.*[1]. To prepare the urinary protein, normal urine was dialysed and concentrated to one-fifth of its original volume at room temperature and reduced pressure. Six volumes of alcohol were added to precipitate the proteins. An examination of this material by paper strip electrophoresis showed the presence of albumin, α_1, α_2 and β globulins, these latter in rather low concentration.

The glycoproteins were hydrolysed with 2 *N* sulphuric acid for 8 hr. at 100° C. in sealed tubes. The hydrolysates were neutralized to *p*H 4·5 with barium hydroxide and the clear filtrate concentrated to a suitable volume. Aliquots were then chromatographed using pyridine/amyl alcohol/water, phenol/water for 3 per cent ammonia, or butanol/ethanol/water as solvent systems. The chromatograms were sprayed with *p*-anisidine hydrochloride in butanol[2]. Mannose, galactose, and a hexosamine were found, corresponding to the results obtained by Werner and Odin[3] for ox seromucoid. The hexosamine was identified as glucosamine[4] and some of it is present in the native protein as the N-acetylated derivative. A faster moving component was invariably present on the chromatograms, however. It was found to have an R_F value corresponding to that of fucose in all the solvent systems used. The intensity of the spot relative to the other sugar components was greater in the urinary material than in the serum mucoprotein.

In order to confirm the identity of this sugar, advantage was taken of the fact that periodate oxidizes methylpentoses to formic acid and acetaldehyde, whereas simple aldoses and ketoses are oxidized to formic acid and formaldehyde[5]. Acetaldehyde can be readily detected by the Rimini reaction[6] with piperazine and nitroprusside, the full scope and limitations of which will be described elsewhere[7]. This test can be applied to paper chromatograms, which are sprayed with 2·5 per cent aqueous sodium metaperiodate. The oxidation is allowed to proceed for ten minutes and then the Rimini reagent is applied. This reagent must be prepared immediately before use by mixing 7 per cent aqueous sodium nitroprusside (1 vol.) with a saturated ethanolic solution of piperazine (3 vol.) and methanolic 1 per cent ethylene glycol (4 vol.). An intense blue spot slowly develops, in the presence of not less than 10 μgm. methyl pentose. The component in the hydrolysate believed to be fucose gave a strongly positive reaction in this test.

2-Deoxy sugars and the amino-acid threonine also give a blue colour under these conditions, but they can be distinguished from the methylpentose by comparison of R_F values and other reactions.

The presence of fucose in human blood-group substances has been shown by Bray and Stacey[8] and in human cervical mucus by Werner and Bergman[9]. Whether serum and urinary glycoproteins have any direct relationship with the blood-group substances, or whether fucose will be found together with other neutral sugars in other body tissues, is now being investigated.

Slow Combustion of Cyclopropane

We have investigated the slow thermal oxidation of cyclopropane by the static method between 380° and 430° C. and at partial pressures of the reactants between 50 and 400 mm. The products are mainly carbon monoxide and water, with small amounts of carbon dioxide and formaldehyde, and the course of the reaction can readily be followed by pressure measurements. There is a period of negligible pressure change followed by rapid acceleration to a maximum rate, during which $\Delta p \propto \exp(\varphi t)$, where t is the time from the beginning of the reaction and φ a constant. Thus, as is the case for nearly all other hydrocarbons and their simple derivatives, the oxidation can be explained in a general fashion as a chain reaction with degenerate branching[1].

The temperature-range over which the rate is measurable overlaps the lower limit of the so-called 'high-temperature' region for slow hydrocarbon combustion, which is given[2] as approximately 400° C. It has been suggested[3] that the kinetics of the 'high-temperature' oxidation (for example, of methane, ethane, ethylene and propane above 390° C.) closely follow that of methane, for which the maximum rate of the reaction is represented by the expression $\rho(\max) \propto [CH_4]^2.[O_2]P$, where P is the total pressure of the mixture[4]. Using cyclopropane, however, while Day and Pease[5] found that, as with methane, no cool flames are observed, the dependence of ρ(max) on the partial pressures of the reactants resembles more closely that exhibited by oxidations in the 'low-temperature' region (200°–300° C.), characterized by a very marked variation of ρ(max) with hydrocarbon concentration but little or no variation with oxygen or total pressure[6]. Thus, at any temperature th is a range of 'low' oxygen partial pressure wit which $\rho(\max) \propto p(C_3H_6).p(O_2)$, and a range of 'hi oxygen partial pressure where $\rho(\max) \propto p^2(C_3$ and independent of $p(O_2)$. The latter dependence in qualitative agreement with the results of th experiments reported by Day and Pease[5] for oxidation at 370° C. The change of dependence usua takes place over a fairly small pressure range, a this 'critical partial pressure of oxygen' increa greatly on increasing $p(C_3H_6)$ or the temperatu In other words, at 'high' $p(O_2)$, 'low' $p(C_3H_6)$ and lower temperatures, the latter dependence is served, whereas at 'low' $p(O_2)$, 'high' $p(C_3H_6)$ and higher temperatures the former dependence observed. However, in no circumstances does addition of nitrogen affect ρ(max) or the induct period.

In the 'low-temperature' region a change fr dependence to independence of ρ(max) on $p(O_2)$, this is increased at a constant value of the hyd carbon pressure, has been reported for the oxidat of several hydrocarbons[6,7]. But it has hitherto be generally agreed that in the 'high-temperatu region ρ(max) is always strongly dependent on oxygen concentration.

The variation of ρ(max) with temperature has be investigated at high and low oxygen pressures. both cases the Arrhenius plots are straight lines w some curvature at the high- or low-temperature e respectively. The overall activation energies for two regions of different dependence of ρ(max) concentration, as calculated from the slopes of straight portions, are the same (∼ 35 kgm.cal./mol and the curvatures appear to be due to alteration dependence with the temperature. It is possible th some of the curved Arrhenius plots which have be reported by other workers[2] for gaseous oxidati are due to this cause.

It may be suggested that the kinetic results ported here are due to the structure of the cyc propane molecule, which has been the subject some controversy[8]. However, the molecule mu presumably contain CH_2 groups, irrespective of type of bond between the carbon atoms. Thus work may be considered to cast some doubt on view that hydrocarbon oxidations in the two te perature-ranges are kinetically very distinct; a in fact, it is possible that ρ(max) would be in pendent of oxygen concentration at any temperat at which slow combustion can occur, if a high enou partial pressure of oxygen were used.

Further work is in progress and it is hoped publish fuller details of the investigation in due cour

We wish to thank the Anglo-I. .nian Oil Compa for a grant.

FORTHCOMING EVENTS

*(Meeting marked with an asterisk * is open to the public)*

Monday, September 15—Friday, September 19

Institute of Metals (at Oxford).—Annual Autumn Meeting.

Monday, September 15—Saturday, September 20

Cement and Concrete Association in conjunction with the uilding Research Station (at the Royal Society of Arts, John dam Street, Adelphi, London, W.C.2; Monday only, September 15, t the Royal Institution, 21 Albemarle Street, London, W.1).—Third nternational Symposium on "The Chemistry of Cement".

Wednesday, September 17

Oil and Colour Chemists' Association, London Section (at anson House, 26 Portland Place, London, W.1), at 7 p.m.—Mr. J. Curtis: "Cadmium Pigments".*

Wednesday, September 17—Friday, September 19

British Ecological Society (in the Department of Zoology, The niversity, Liverpool).—Autumn Meeting.

Thursday, September 18—Saturday, September 20

Society for Water Treatment and Examination (at Sheffield) —Autumn Meeting.

Friday, September 19—Saturday, September 20

Biochemical Society (in the Department of Biochemistry, The niversity, Glasgow), at 11 a.m.—Scientific Papers.

Society of Leather Trades' Chemists (in the Large Chemistry ecture Theatre, The University, Leeds).—Annual Conference.

riday, September 19

At 2 p.m.—Prof. J. B. Speakman: "The Reactivity of Protein ibres; some Analogies between Keratin and Collagen" (Fifth Procter emorial Lecture).

Friday, September 19—Monday, September 22

Aslib (at The Hayes, Swanwick, Derbyshire).—Twenty-seventh Annual Conference.

Friday, September 19

Prof T U. Matthew: "The Significance of Information in Present-lay Industrial Society".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned.

Assistant (with an honours degree in biochemistry, or its equivalent) in the Biochemistry Department—The Secretary, The University, Aberdeen (September 18).

Lecturer (with high academic and research qualifications) in Chemistry—The Clerk to the Governors, Chelsea Polytechnic, Manresa Road, London, S.W 3 (September 19).

Demonstrator in Electrical Engineering and Physics—The Principal, Royal Aircraft Establishment Technical College, Farnborough, Hants (September 20).

Scientist, Grade III (with a first- or second-class honours degree in physics, preferably with a knowledge of electronics, workshop practice, and general physics) at the Central Laboratory, Shade House, Bolton Road, Pendlebury—The Divisional Establishment Officer, National Coal Board, North-Western Division, 40 Portland Street, Manchester 1 (September 20).

Electronic Engineer for the construction and servicing of high gain amplifiers for physiological recordings at different frequencies—The Secretary, Maida Vale Hospital for Nervous Diseases, London, W.9 (September 21).

Lecturer in Biology, to teach mainly zoology up to B Sc. general degree standard—The Principal, Acton Technical College, High Street, Acton, London, W.3 (September 21).

Non-Medical Biochemist (university graduate holding the B.Sc. in chemistry or biochemistry, or associate of the R I C.)—The Superintendent, Royal Hospital, West Street, Sheffield 1 (September 24).

Statistician (Scientific Officer grade)—The Secretary, National Vegetable Research Station, Wellesbourne, Warwick (September 24).

Engineers to the Ministry of Supply in Lancashire, for inspection of wide variety of plant and equipment—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting C.456/52A (September 27).

Crop Physiologist to work on effect of climatic factors prevailing in Scotland on growth and cropping of horticultural crops, an Applied Geneticist for genetical studies, to develop varieties of horticultural plants for special use in Scotland, a Mycologist to work on problems connected with red core in strawberries, particularly those arising from development of physiological strains of this fungus, an Entomologist to work on incidence, life histories, pest range, etc., of insects which are known or may possibly act as vectors of virus diseases to horticultural crops in Scotland, a Horticultural Botanist to work on problem of vegetable culture in Scotland, and an Entomologist to act as field and laboratory assistant in the Plant Pathology Section —The Secretary, Scottish Horticultural Research Institute, Vernonholme, Riverside Drive, Dundee (September 30).

Lecturer in Physiology—The Registrar, King's College, Newcastle-upon-Tyne (September 30).

Lecturer (Grade II) in Chemical Pathology, and an Assistant Lecturer (Grade III) in Veterinary Pathology, at the Veterinary Field Station, Langford, Somerset—The Registrar and Secretary, The University, Bristol (September 30).

Veterinary Research Officer in the Sudan Veterinary Service—The Sudan Agent in London, Wellington House, Buckingham Gate, London, S.W.1 (September 30).

Junior Lecturer in Bacteriology—The Secretary, London Hospital Medical College, Turner Street, London, E.1 (October 4).

Head of the Department of Natural Sciences, a Senior Lecturer or Lecturer in Botany, a Senior Lecturer or Lecturer in Engineering, and a Lecturer in Geography, in the Nigerian College of Arts, Science and Technology—The Secretary, Advisory Committee on Colonial Colleges, 15 Victoria Street, London, S.W 1 (October 6).

Lecturer in Bacteriology, a Lecturer in Geology, and a Lecturer in Philosophy, at the University of Adelaide—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (Adelaide, October 15).

Chief Sewage Chemist—The Town Clerk, Town Hall, Bradford, endorsed 'Chief Sewage Chemist' (October 17)

Research Officers in the Soil Survey and Pedology Section, Division of Soils (initially at Adelaide and Canberra), for soil surveying and pedological investigations requiring approximately six to seven months each year in the field—The Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2, quoting No. 3968 (October 18).

Lecturers and Senior Lecturers in Primary and Non-Ferrous Metallurgy, and a Teacher in Coal Mining, at the New South Wales University of Technology—The Agent-General for New South Wales, 56 Strand, London, W.C.2 (October 27).

Lecturer in Physics (with special qualifications in theoretical physics)—The Secretary, Queen's University, Belfast (November 30).

Lecturer in Experimental Pharmacology—The Secretary of the University Court, The University, Glasgow, W.2 (December 31).

Arrowroot Processing Chemist (with a degree in chemistry and experience in starch technology) in St. Vincent—The Director of Recruitment (Colonial Service), Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1, quoting No. 27106/62/52.

Assistant Director of Botanical Gardens, Singapore—The Director of Recruitment (Colonial Office), Colonial Service, Sanctuary Buildings, Great Smith Street, London, S.W.1, quoting 27059/261.

Assistants (Grade A) to teach Mathematics up to degree standard —The Clerk to the Governors, South-East Essex Technical College, Longbridge Road, Dagenham, Essex.

Biochemist in the East African Tsetse and Trypanosomiasis Research and Reclamation Organization, to carry out research on animal and insect physiology in connexion with trypanosomiasis investigations in East Africa—The Director of Recruitment (Colonial Service), Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1, quoting No. 27106/63/52.

Engineer (Design) in the Department of Rural Water Development, Gold Coast—The Gold Coast Office, Melbourne House, Aldwych, London, W.C.2.

Inspector of Mines (with a degree or diploma of a recognized school of metalliferous mining and at least three years practical experience including underground mining) in Uganda—The Director of Recruitment (Colonial Service), Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1, quoting C.S.D.63/9/01.

DISTRIBUTION OF RESEARCH EFFORT IN BRITAIN

FIVE years ago, the Federation of British Industries published a statistical survey of scientific and technical research in British industry, based on an inquiry conducted during 1945–46 by its Industrial Research Committee. That survey was of particular interest as providing a forecast of the demands of British industry for research workers and technologists. Since then, we have had the reports from sub-committees of the Technical Personnel Committee of the Ministry of Labour and National Service, and a comprehensive report on chemical industry from the Association of British Chemical Manufacturers, as well as relevant reports from 'productivity teams', such as that on industry and the universities, of the Anglo-American Council on Productivity, and a report on scientific man-power from the Advisory Council on Scientific Policy.

The second survey of the Industrial Research Committee of the Federation, based on the year ended on or before March 31, 1951, which has now been published*, is thus of interest, less in relation to the man-power situation than from the point of view of the balance of the national research effort in general, and particularly in relation to development and industrial efficiency and productivity, on which such stress has been laid since the first survey appeared. Although a further five hundred copies of the questionnaire were circulated to industrial firms, a much smaller proportion of replies was received; and the 301 replies which were sufficiently detailed for analysis obviously represent too small a sample for sound or really authoritative deductions. These 301 firms were spending during 1950–51 the sum of £23,779,000 on research and development. If they are as representative a sample as the 420 firms of the earlier survey, the expenditure of which was £21,815,000, it might be inferred that expenditure has increased by about 50 per cent. On the other hand, an analysis of the expenditure of 107 firms common to both surveys suggests an increase of 100 per cent, and allowing for the difficulties in making an accurate estimate, the increase over 1946, on an expenditure basis, is probably somewhere between 50 and 100 per cent. On the assumption that the latest survey is as representative as the first, the total annual expenditure by industry on research and development within its own establishments could be put as between £45 millions and £60 millions.

This cannot, however, be assumed to represent a proportionate increase in research effort. Inflation in the past five years has reduced the value of the pound by a fifth, and the cost of equipment and salary-levels have both increased. From the point of view of research effort, this expenditure should be assessed first against corresponding expenditure in other fields, and secondly, against the numbers of qualified staff employed in research and development.

---

* Research and Development in the British Industry: a Survey of Expenditure on Industrial Research and Development in the Year 1950–51 made by the F.B.I. Industrial Research Committee. Pp. 19. (London: Federation of British Industries, 1952.) 1s. 3d.

On the first criterion, it should be noted that the survey excluded firms which reported a research and development expenditure of less than £2,000 per annum. The smaller firms, however, still represent the bulk of the industrial units of Great Britain: less than one per cent of our industrial units employ more than 500 people each; some 92 per cent employ less than 50, and it is these smaller firms that constitute the major problem in securing the more widespread and effective utilization of scientific knowledge in production. To some extent their research needs are met by the research associations, which like the nationalized industries are excluded from the survey. The expenditure of the forty-two research associations during 1950–51 was £3·4 millions, of which £2·15 millions was contributed by industry, as against £1 million by the twenty-six research associations of 1945–46, in which was included £570,000 from industry.

It is not easy to get a clear picture of the distribution of the research effort of Great Britain as between industry, government establishments and the universities. In the House of Lords debate on June 11, the Lord President of the Council put State expenditure on civil research at £16 millions a year, apart from that included in the £18 millions provided for the universities. Besides £5·5 millions on the Department of Scientific and Industrial Research and the research associations, this £16 millions includes £1·5 millions on medical research and £3 millions on agricultural research; and in the same debate Lord Waverley put the total expenditure on industrial research in the great firms and in the Department of Scientific and Industrial Research at not less than £50 millions a year. Excluding research on nuclear physics, current expenditure on fundamental research in the United Kingdom was put by the 'productivity team' on the universities and industry at not more than £1·5 millions, compared with some £30 millions expended in the same way in the United States.

These estimates are presumably based in part on the £141 millions for research and development in the Civil Estimates for 1951–52; for 1952–53 the corresponding figure is £161,433,349. But it is difficult to obtain an adequate breakdown of this figure or of the £650 millions for production and research in the defence estimates for 1952–53 (an increase of £250 millions on 1951–52). The 1952–53 Civil Estimates includes the sum of £13,893,500 on research and development in the Navy estimates and £1,350,000 for Colonial Development and Welfare Research Schemes, but not that part of the £25 millions for universities and colleges which goes on research. It includes nearly £2 millions for the Medical Research Council, £1 million for the Agricultural Research Council and a further £1·9 millions for research and development work under the Ministry of Agriculture and Fisheries, as well as some £650,000 for the Department of Agriculture for Scotland. Just over £1 million goes to the Ministry of Works. The major item, however, is £128,308,000 for the Ministry of Supply—an increase of £18 millions on the corresponding vote last year. Of this, £52,750,000 is for research and development work carried out by industry or extra-mural work by t universities, while £7,896,380 is accounted for by t civilian staff of the Research and Developme Division and £483,484 by that of the Directorate Scientific Research and Technical Division.

Although details of the staff employed in t various directorates and divisions of this Minist are included in the Civil Estimates, it is not easy gain a clear picture of the research effort for whi it is responsible in terms either of money or staff. I complicated character is apparent from what h already been said, and in his highly critical comme on June 12 Lord Falmouth stated that the Minist employed a staff of 1,051 scientific officers, 1,0 assistant scientific officers and 1,444 technic assistants. The civilian staff of its Research a Development Division alone numbers 14,449, with further 2,300 in the Directorates of Atomic Energ of Guided Weapons and Electronics, of Scienti Research and Technical Development, the Ch Scientist and the Chemical Inspectorate.

With all allowance for the value to industry work done in this Department, the government sta employed on research and development in this w look considerable when placed alongside the 3,7 employed by the Department of Scientific a Industrial Research, or even the 31,000 perso estimated by the Federation of British Industries engaged full time by the 301 firms on research a development work. Of these, about 8,500 possess university degree or equivalent qualification. B the survey attempts no estimate of the number persons employed full-time in industry as a whole research and development. The earlier survey p this at roughly 45,000, of whom about 10,000 we qualified scientific men or technologists. An analy of the qualified staff of some 254 firms as at 1946 a 1950 indicates an increase of about 50 per cent, a while there is evidence of a slight general increase the ratio of unqualified to qualified staff, it wou appear from this survey that the number of qualifi scientific men and technologists employed by industr on research and development is unlikely to exce 15,000 in a staff of perhaps 65,000 to 70,000.

Among this qualified staff, chemists are still t most numerous; but their 38 per cent is now fo lowed closely by engineers (35 per cent), physicis coming third with 11 per cent, compared with 4 33 and 10 per cent, respectively, in 1946. In the 254 firms the number of chemists employed increase from 2,357 to 2,945, of engineers from 1,455 to 2,6 and of physicists from 844 to 2,357. The number biologists was 182 in place of 92, of mathematici 115 compared with 61, and metallurgists 416 in pla of 293. Expenditure per unit of qualified staff vari from a little more than £2,000 in heavy electric engineering to more than £4,000 for glass and f textiles, compared with £1,600 to £2,300 in 194 The ratio of unqualified to qualified staff a fluctuates considerably, varying from about 2 i glass and in the scientific instruments and heav electrical engineering groups to 5 2 in light electric engineering, but generally shows a slight upwa trend.

The total floor space of the research and development departments of 249 firms has increased by 4 per cent since 1946 and is approximately 1,000 q. ft. per qualified member of staff. Research and development expenditure expressed as a percentage f turnover varied considerably in the industrial groups analysed, being as little as a half per cent in extiles, the ferrous metals, and the food, drink and obacco group and as much as five per cent for light lectrical engineering and scientific instruments. The gure of 2·4 per cent for the chemicals group compares with that of 3 per cent for Imperial Chemical Industries, Ltd., in 1950 given by Sir Wallace Akers o the International Symposium on the Organization f Scientific and Industrial Research.

On the evidence of this survey, the research and evelopment effort of British industry is unlikely to ave increased by more than 50 per cent since 1946, nd the upper estimate of about £60 millions contrasts with Dr. Vagtborg's estimate of an expenditure n research of 600 million dollars by American ndustry, or 2,000 million dollars if development work s included; Lord Hall, in the debate on June 11, quoted a figure for 1951 of £900 millions. This omparison, moreover, ignores the question whether he research effort is wisely directed at the right argets, and whether the best use is made of technological and scientific man-power, so that it is not wasted on tasks that could be equally well performed y clerical, administrative or less highly trained echnical staff.

Such questions, however, are all-important in considering the distribution of the research effort of Britain, and particularly the proportion that is arried out directly or indirectly under the auspices of the State, a point Lord Falmouth was inclined to overlook in his criticism of the Ministry of Supply. By and large, however, the expansion of research and development in British industry lags behind that of other countries, and as Sir Henry Tizard maintained n his Messel Memorial Lecture at Aberdeen on July 9, its dependence on the State is increasing.

The survey made by the Federation of British Industries is purely factual: no attempt is made to discover or discuss the causes of the trends revealed. It is the more useful, therefore, to examine the survey n the light of some of the replies received to questionnaires sent out by the Parliamentary and Scientific Committee to various affiliated scientific institutions and research organizations, as well as to the directors of research of some major industrial firms, in connexion with the debate in the House of Lords on June 11 and 12. A number of the replies confirmed the view expressed in that debate and elsewhere that the lack of a sufficient number of trained scientific men and technologists, particularly on boards of directors, is an important factor in delaying the application of research results in industry. This deficiency is being gradually remedied, and the discussions on higher echnological education have focused a fair amount of attention on it; though in this connexion and particularly while the shortage of certain categories of scientific men persists, more attention could well be given to the most effective use of the time of such men. The ratios of qualified to non-qualified staff quoted in the Federation of British Industries survey appear to justify one comment by the Parliamentary and Scientific Committee that more use could be made of less highly qualified staff on duties which do not really demand the expert knowledge, for example, of a trained chemist.

Much emphasis was laid in the replies to the Parliamentary and Scientific Committee's inquiry on the obstacles to development presented by the present fiscal policy in regard to plant obsolescence, and by the long delays experienced in obtaining delivery of plant or equipment, licences for plant extensions and other capital projects, as well as to the danger that rapidly mounting costs of re-equipment and plant alteration are tending to involve capital expenditure beyond the resources of a small company. Such factors, which are a direct result of Government policy, tend to overshadow the conservatism of the British manufacturer and consumer. Sir Henry Tizard was right to appeal for a greater spirit of adventure on the part of industry; but British industry will also be grateful for his outspoken reference to the way in which taxation policy discourages industrial adventure. The point is one which the Parliamentary and Scientific Committee might take up strongly.

Apart from the shortage of qualified scientific men and technologists, particularly of engineers, chemists, physicists, metallurgists, chemical engineers and physical chemists, replies to the Parliamentary and Scientific Committee's inquiry suggested that the rapid application of scientific knowledge in industry is being hindered not only by the absence of sufficient numbers of those able to assimilate and apply such knowledge, but also to some extent by defective means of dissemination. Both presentation and interpretation require improvement, and Sir Wallace Akers, who in commenting on the staff position had stressed the importance of quality rather than quantity, and the serious effect on the teaching of science in schools of the scarcity of really good scientific staff, urged Government assistance in the publication of original scientific papers and abstract journals.

Generally speaking, the replies to the Parliamentary and Scientific Committee's inquiry contributed little that is new, and the general trend of opinion was faithfully reflected in the House of Lords debate. Strong support was forthcoming for more generous support for the research associations and the government research stations, and there was no suggestion that the distribution of research effort as between industry, government establishments and the universities is unbalanced; nor was concern expressed that there is excessive reliance upon the State. Sir Wallace Akers, indeed, referred to a suggestion that the Department of Scientific and Industrial Research's grant system should be extended to encourage the appointment of effective field-teams, particularly in those research associations serving industries which are not remarkable for their technical progress. He also commended a suggestion that the research associations might be used as recruiting agencies for the corresponding industries by establishing training schools within the associations themselves to provide courses for production and research staff for these industries.

The educational potentialities of the research associations deserve more attention than they have yet received, both in regard to the expansion of technological education and from the point of view of industrial recruitment and the movement or interchange of staff both with industries and with the colleges of technology or even the universities. This is a further reason for viewing with concern the recruiting difficulties to which the Advisory Council for Scientific and Industrial Research directs attention in its recent report, and for probing further the reasons for the reluctance of many of the best science graduates to enter the government scientific service.

That, of course, is independent of the question whether or not, in fact, an undue proportion of the nation's scientific effort is being made under government auspices. The question of quality, however, scarcely enters into the strictly factual survey of research conducted by the Industrial Research Committee of the Federation of British Industries, though it was clearly in the minds of some at least of those who replied to the questions of the Parliamentary and Scientific Committee. None the less, the survey, like the memorandum of the Parliamentary and Scientific Committee, gives a picture of the present position and an indication of some of the trends and the close relation of industrial research and development to such matters as technical and technological education and the effective dissemination of the results of research, in which circumstances to-day have increasingly thrown large responsibilities on the government. The observations and suggestions will no doubt be carefully considered by Lord Woolton and by Lord Cherwell on behalf of the Government, and it is to be hoped that they will bring the necessary note of urgency to the formulation and execution of an adequate policy, both in regard to industrial research and development and such ancillary matters as technological education.

SCIENCE AND SOCIETY

The Impact of Science on Society

By Bertrand Russell. Pp. 140. (London: George Allen and Unwin, Ltd., 1952.) 7*s*. 6*d*. net.

THIS book, which appeared appropriately as Lord Russell celebrated his eightieth birthday, has more unity than might be expected from the prefatory statement that it is based upon lectures originally given at Ruskin College, Oxford, and that the last chapter, which discusses the stability of a scientific society, was given as the Lloyd Roberts Lecture at the Royal Society of Medicine, London, on November 29, 1949. For some readers the book's main interest may derive from its revelation of Russell himself, but it is something more than the musings or reflexions of one of the most brilliant intellects of our times. Here is no octogenarian living in the past. Once again the gifts that have stimulated two generations play over the problems that scientific advance in the last three centuries have created 1 mankind—the clash between science and traditi the general and the specific effects of scienti technique in an oligarchy or totalitarian regime a in a democracy, the relations of science and war a of science and values, and the stability of a scienti society, whether dictatorship or democracy. he is sometimes more subtle than in some earl books and the gentleness of age leaves it for t reflective reader to discover how penetrating a stimulating some of his comments and observatic really are, we have still in good measure the impi almost Puck-like wit that we have long been acc tomed to from one whose intellectual eminence linked with the freshness of youth.

Save where in his first chapter he touches science and tradition and stresses three factors in t scientific outlook of the eighteenth century that we specially important in developing the mechanis outlook, and again when he discusses the philosopl of human power, the philosophical element in tl book is slender. This, however, is what gives t book its distinctiveness, as may well be seen if it set beside the study, similarly entitled, and of li length, to which fifteen years ago Lord Stan expanded his presidential address to the Briti Association. On the general effects of scienti technique on society, the problems of science ai war and even the question of science and value both Russell and Stamp have much to say that similar. Both were convinced that one of the ma consequences of scientific development is to increa the interdependence of peoples, and that scien offers possibilities of far greater well-being for tl human race subject to the fulfilment of certa conditions. Even on those conditions they wou seem to be broadly in agreement. As defined b Russell these are: the abolition of war; even di tribution of ultimate power; and limitation of tl growth of population. Stamp was largely concerne with the devising of practical measures to preve the stresses arising from social or industrial di equilibrium due to excessive rate of change, and h agreement with the second condition is implicit rath than explicit. On the first and third, Russell is r more emphatic than Stamp, for all the experience the intervening years, which has shown the necessit for finding some means of averting recourse to w and of limiting the growth of population if the worl is to avoid either destruction of civilization starvation.

The difference in emphasis and in outlook betwee the two studies lies in the quickened appreciation the importance of the problem of power which mark that of Lord Russell. Not all the aspects of th problem are indeed illuminated by him: at some the darker problems, such as that of the control mind and personality, Russell only hints. He concerned above all with the problem of officialdo in the scientific society which may confront us, a if to the question how the government itself is to controlled by the governed he gives no clear answe much in his book should stimulate the scientist deep thought, whether he is concerned primarily w the future of science or that of society.

When he touches on the practical problems of ho world government is to be achieved, the growth population controlled, or the abuse of power pr vented so that freedom of initiative and expressio are ensured in the new context, Lord Russell disappointing. He closes, indeed, on a note timism rather than pessimism ; but he is hopeful ther than confident. His firm condemnation of the aticism of our times is not matched by the same surance in giving his reasons for thinking that ankind may avoid the disaster which such fanatic- n and refusal to adjust its activities in the light of ason threaten to bring. He discounts unduly the rt played by emotions in human affairs, seems to gard emotion as necessarily or essentially evil, and discard religion with the fanaticism he denounces. rhaps for this reason—whereas Stamp, calling for advance in the science of man commensurate with e advance in the science of matter during the past ree centuries, leaves us facing the future with some nfidence that we can regain control over events— ssell, declining to believe that the world war and rld disaster are inevitable, for all the factors which delineates as tending to bring them, leaves us shing that wisdom and reason may prevail rather an with the serene confidence of those who have en and believe in the greatness of man and who are in the appreciation of what is noble, beautiful, ntle and wise, and in the vision of a society, where dividuals grow freely and where hate and greed and vy die, of which he spoke in his broadcast reflexions his eightieth birthday. R. BRIGHTMAN

MOLECULAR SPECTRA AND MOLECULAR DYNAMICS

olecular Spectra and Molecular Structure

: Spectra of Diatomic Molecules. By Gerhard erzberg. Second edition. Pp. xv+658. (New ork : D. Van Nostrand Co., Inc. ; London : Mac- llan and Co., Ltd., 1950.) 9.75 dollars ; 73*s*. 6*d*. net.

ROM time to time a landmark appears along the hard road towards the complete understanding molecular dynamics, serving not only to please d encourage, but also to stimulate us to further fort. Such is this book, a work of authority, of lendour and polish, and—in spite of its encyclo- edic content—of absorbing interest. The first ition was published twelve years ago at the outset the Second World War, and few copies were avail- le outside the United States, so few indeed that y own copy was almost continuously on loan. This w volume is the most thorough treatment and ference work on the spectra of diatomic molecules t published. It covers ground which is equally portant in physics and chemistry, and in revising e book the author has added new sections on icrowave spectra, Zeeman and Stark effects, hyper- e structure, and many aspects of photodissociation, well as giving us some promising new data on rophysical phenomena.

Dr. G. Herzberg's clarity as a lecturer is well own, and this is reflected in his books. He has sembled here all the salient theory of molecular namics required for the interpretation of rotational, brational and electronic band spectra, amply illus- ted by numerical results and photographs, and ectly applied to a variety of typical cases. All this presented in a logical readable form. There is too ten a tendency by some workers in this field to othe the subject-matter in a shroud of forbidding athematical formulation, which leaves the ordinary ader or the student both exhausted and in despair. r. Herzberg deals properly and adequately with such mathematical theory as is needed for the problems involved and, incidentally, provides a clear exposition of the wave-mechanical principles ; he never fails, however, in illuminating asides, to seek some attractive physical picture or visualizable analogy, as, for example, his model to illustrate the meaning and mode of action of the Franck–Condon principle. The somewhat puzzling topics of vector coupling of momenta, of the symmetry properties of different energy-levels, and of ortho- and para-modifications are also clearly discussed, and all the ramifications of the rotational fine structure associated with electronic-vibrational transitions are set out.

The later parts of the book deal with the dissociation processes associated with different kinds of continuous and diffuse spectra, and with the electronic structure of molecules in relation to stability and interatomic forces. The derivation of molecular data such as heats of dissociation and potential energy diagrams is explained fully, and in a critical manner.

Finally, an up-to-date table is given of the energy-levels, vibrational frequencies, anharmonicity co-efficients, rotational constants and other desirable data, which will long remain a place of reference for all those working in this field and for many others less directly concerned. More data are now becoming available about the higher vibrational levels of molecules in the electronic ground-state, studied with high-dispersion grating spectrometers and very long absorption paths, and the greater precision which is now possible may well lead to a revision of some of the molecular constants listed in this table. Yet this does not in the least detract from the enormous value of Herzberg's compilation. This is, in fact, an admirable book. H. W. THOMPSON

SUGAR BEET DISEASES IN IRELAND

Sugar Beet Diseases in Ireland

By Prof. Robert McKay. Pp. ix+78+37 plates. (Dublin : At the Sign of the Three Candles, 1952.) 21*s*.

TO his illustrated guides for the recognition and control of flax and tomato diseases Prof. Robert McKay now adds this third volume, and like its predecessors it is attractively produced, beautifully illustrated, and reveals first-hand knowledge of the subject. Sugar beet has been grown commercially in Ireland for a quarter of a century, and the crop is subject there to much the same diseases as occur in England, though not always in the same degree. Black leg, for example, causes considerable loss every year and is not controlled by seed treatment with organo-mercury dusts, whereas in England, where seed treatment is a routine operation, this disease, though common, is rarely destructive.

The very heavy loss in sugar yield (about £6,000,000) experienced in England in 1949 as a result of the worst epidemic of virus yellows known there, has not been paralleled in Ireland, and both mosaic and downy mildew are evidently also of less significance. This may well be due in no small measure to the action of the Irish Sugar Company, which, following moderate epidemics of virus-yellows and downy mildew in 1946, insisted on stecklings being grown in complete isolation from seed and root crops, and on seed and root crops being grown in separate fields and as far apart as possible.

Until 1940, all supplies of mangold and beet seed had been imported into Ireland from the Continent; then it became necessary to produce home-grown seed, and for convenience the seed crop was raised in the same fields as the roots. As a result the major diseases increased rapidly during the next six years. No severe epidemics have occurred since compulsory isolation was introduced in 1947; but recent partial failures clearly indicate that it is not sufficient merely to raise stecklings in isolation. The steckling areas must be chosen carefully, and build-up of virus in them must be prevented by keeping down groundkeepers under a proper rotation.

Prof. McKay describes about two dozen diseases. His main conclusion is that their control is a matter of prevention rather than cure, of good husbandry rather than protective spraying. His story is an interesting one, and should be readily understood by anyone interested in sugar beet production. Ten of the thirty-seven plates are in colour; there is a glossary of the fifty or so technical terms used; and an author as well as a subject index.

W. C. Moore

TRANSCENDENTAL PHENOMENOLOGY

Ideen zu einer reinen Phänomenologie und phänomenologischen Philosophie

Von Edmund Husserl. Buch 1 (Husserliana, Band 3): Allgemeine Einführung in die reine Phänomenologie. Neue, auf grund der Handschriftlichen Zusätze des verfassers erweiterte Auflage. Herausgegeben von Walter Biemel. Pp. xvi+483. 20 guilders. Buch 2 (Husserliana, Band 4): Phänomenologische Untersuchungen zur Konstitution. Herausgegeben von Marly Biemel. Pp. xx+426. 19 guilders. Buch 3 (Husserliana, Band 5): Die Phänomenologie und die Fundamente der Wissenschaften. Herausgegeben von Marly Biemel. Pp. vi+167. 6.75 guilders. (Haag: Martinus Nijhoff, 1950–52.)

With these three stately volumes, the scholars of the Husserl-Archiv at Louvain bring their immediate task to an end. It would, however, be incorrect to write "Husserliana concluded", because there is some reason to suppose that further material of outstanding consequence to philosophers is still being worked over, and that, ahead again, we may be presented one day with an authentic biography of the master himself. In a recent discussion with Husserl's daughter, I gained the impression that the treasure-house has not yet been exhausted, which only underlines the debt which all serious students of the subject owe to Prof. H. L. Van Breda and his colleagues for their long labour of love. The present editions are the work of Dr. Walter Biemel and of Marly Biemel, and between them account completely for Husserl's researches and their development during the period 1913–25. Much of importance is to be found in a series of supplements to the main text, embodying somewhat copious rescripts. It is clear that publishers and printers have given of their best.

The first book contains the complete theory of phenomenological reduction, including the derivate factor of pure consciousness and its essence-correlate. An attempt follows to obtain a clear-cut approach to the former, with its influence upon recent scientifi trends. In the second book the relation of phenomenology to the physical sciences, psychology an aesthetics is discussed. Here, the establishment o suitable pre-conditions is recognized as the firs essential, and permits a deepening of previou knowledge.

The purpose of the third book is to probe the 'idea of philosophy, in the light of the possibility o developing a norm of absolute knowing. Cognitio at this level is seen as the pre-condition for an system of metaphysics (and former philosophies, too) which are in principle capable of appearing a sciences. It may be remarked that, in this context some concordat is to be expected with an extende *philosophia perennis*, a point brought out some yea ago from another angle. This may, of course, prov to be but a minor matter; what is more significan is that, by reflecting upon the ontological basis of th sciences, Husserl is gradually leading up to th feasibility of science offering—and in the even accepting—fundamental criticism of itself, and tha at its own level. A recent author, in discussing th "Theodicy" of Leibniz (1710), has given reasons fo thinking that a re-birth of metaphysics will assuredly come about one day: that this should be said jus now, coupled with the prophetic insight of phenomenology, raises hopes that metaphysics may ye assume the role of a progressive discipline, and thu qualify to be regarded as a necessary outcome—among others—of Husserl's "Ideen". It is only too manifest that this is not the part which metaphysics is traditionally credited with playing, if the history of thought is widely analysed. Sometimes, fo example, we find it neatly sliced away from contac with all experimental techniques, and left to justify itself, if it can, as a convenient mental short-cut when observational work had become tedious, o mathematics too hard. At other times, when a mos valuable time-saving science—witness the rise o chemistry, which by its own efforts reached a empirical summit, unscaled by physics for ages—i discovered and pressed home, nobody would dream that, in a sense, a species of metaphysics was being evolved without ontological regard.

These are not exactly questions which can b settled by yea or nay; what matters is that a philosophical climate should be provided, such that in it, they may be recognized as specific problems even if insoluble for the general case. The structure underlying the doctrines of the present volumes i one at least capable, in theory, of embracing these situations.

Of these three contributions, therefore, it may b said that they represent the fullest development o Husserl's transcendental phenomenology, and that in a form embodying the most polished finish of whic his system is capable. But there must be a tool, *Methodik*, especially one deliberately fashioned to c through to a philosophy which can lay claim to prior to all (other) knowledge and scientific ratiocination. This weapon, the general character o which has been sketched on previous occasions, i the principle of phenomenological reduction. It purpose is to attain to a pre-suppositionless regio with its emphasis upon pure consciousness (th individual ego), and in such a way as to be free from pre-judgment. The residue, after reduction, is the 'stuff', so to speak, of phenomenology, and the facto upon which it operates. A crude image of what thi means would be the suspense account with which w more or less familiar in administrative affairs. rein something is laid by for the time being, and judgments passed upon it; for Husserl this comses the world, and all 'posited' things. The German *geschaltet*, often translated 'eliminated', does not olly satisfy British minds; it inclines too heavily wards finality. To borrow an expression from ctrical engineering, 'switched-out' is probably arer the true connotation. There is then nothing prevent us from throwing in the 'breaker' again enever circumstances permit.

In bringing to a close this series of essays on sserl's phenomenology which have appeared in *ture*[1], it may be legitimate to take a final glance the panorama spread out before us, now that the ours of the archivists have been so well implented. Husserl was convinced to the end that his earches had indeed disclosed the existence of a *ena* of thought, free from vestiges of prepposition, and endowed with perfect rigour. If pact upon the world of learning is any criterion of rth, then, as the original memorial volume to the ster's memory illustrated, his influence is already et. More particularly is this so in the *Geistessenschaften* (psychology, psychiatry and so forth), ich are the most difficult to discipline, just because ey are youthful and full of promise. There perhaps, re than anywhere else, is the value of suspense of dgment (reduction) most in evidence. The relative rits—or limitations—of *Gestalten* and association e still not fully resolved: as one example among ny.

Finally, this may be the place to record the death Prof. Husserl's widow, on November 21, 1950, at e age of ninety. It seems almost incredible that en she was nearly eighty she contrived to get her sband's papers out of Germany, and into the nerous care of the authorities at Louvain. Surely, t feat alone is her fitting memorial.

And now the little band of scholars, some dozen ars after the event, can lift up their eyes and look on the fields, for they are white already to harvest.

A PROSPECT FOR ESTATE WOODLANDS

tate Forestry

y Sir William Ling Taylor. Pp. xi+200+12 plates. ondon: Crosby Lockwood and Son, Ltd., 1951.) s. net.

IR WILLIAM TAYLOR, who was for many years a member of the Forestry Commission of Great itain, ultimately becoming director-general, adesses this book to "the owners, agents and foresters o are concerned with the management of private tate woods". As this is one of the few books of any se to be published about estate forestry since the cond World War, it will certainly provide food for ought among those to whom it is addressed.

It comprises twenty-two chapters, of which the st three deal with forestry in general: its background, its problems and its national aspects. The xt five chapters are concerned with sylvicultural oblems and notes on broad-leaved and coniferous ecies. These are followed by five chapters on rseries, planting, tending and maintenance, and coppice. After this, two chapters on damage and protection are included, and four chapters on the business side of forestry, including marketing, taxation, co-operative groups, with a chapter entitled "Forestry and the Farm". The last two chapters deal with the forest year and forestry books.

It is a very good thing to see that a chapter on the farmer's trees has been included, for in the past too little importance has been attached to farms as potential sources of timber. Since 1940 hedgerow trees have made a very useful contribution towards the timber needs of Britain. If it were only possible to persuade farmers that trees are worthy of better treatment than as fence posts, it would indeed be a step forward.

The question as to whether forestry pays or not is a problem which must be present in the minds of many who are concerned with woodland management at the present time. In answering this question, however, it is to be regretted that the author did not provide figures relating to the actual cost of the usual forest operations. Forestry is a business and, as in all businesses which are to remain solvent, one must know what the costs of production are.

The views which the author expresses on some points will not be accepted without question by some of his readers. His statement that "workers new to the woods, if well supervised, speedily acquire skill and soon become able to notch-plant up to a thousand transplants in a day's work" needs some qualification.

On the subject of the best tool to use for pruning, he says "there is little doubt that the best work is done with a sharp well-set hand pruning saw used in conjunction with a light ladder". This may be the experience of the author, but those who have seen the excellent results obtained with such chisel pruners as the 'Whitmore Pruner' may feel that Sir William is somewhat dogmatic.

The book is well produced and has a number of very good photographs, together with a synopsis of the Forestry Act, 1951, included as an appendix.

N. D. G. JAMES

STUDY OF THE WOOD RAT

The Dusky-footed Wood Rat

A Record of Observations made on the Hastings Natural History Reservation. By Jean M. Linsdale and Lloyd P. Tevis, Jr. Pp. x+664. (Berkeley and Los Angeles: University of California Press; London: Cambridge University Press, 1951.) 56s. 6d. net.

THE dusky-footed wood rat (*Neotoma fuscipes* Baird.) is a medium-sized rodent native to North America. It and other species of the genus *Neotoma* are also called pack rats, trade rats, brush rats and cave rats. It rarely leaves its normal living-quarters in the wilds, though it sometimes comes to isolated habitations of man. Wood rats are nocturnal and are seldom seen without special search, but the conspicuous houses in which they live, built of sticks above ground, readily show their presence. The subspecies dealt with in this book is *N. f. luciana* Hooper of coastal central California.

The authors have investigated all the aspects of the biology and ecology of this animal for ten years on the Hastings Natural History Reservation in Monterey County, California. They have made an intensive study of this comparatively small area and of the individual rats that lived there during successive generations. Their trapping methods made possible the repeated handling and examination of the rats, which were often kept under observation for the whole of their life-spans.

The population studied was more stable than that of most rodents, the stability reflecting a continuous and precise adjustment to the brushland and woodland where the animals live. A wood rat's ability to survive is affected by the conditions that enable it to leave its home and those that affect it away from shelter. A rat that lives in a house providing protection from the weather and predators is exposed to these dangers when away from home. It leaves its house mainly to get food and housebuilding material, to escape from dangerous intruders or intolerant members of its own family, and to find other rats.

Many rats contribute to the maintenance of few houses, which last much longer than any single occupant, but the character of each house is dictated by its situation and the available materials; it remains constant in type through successive tenancies. After a period of vacancy a house falls to pieces because it loses its 'sign', such as odour, deposits of fæces and urine, and gnawings; it is then no longer recognized by the rats as a house.

The wood rat is polyœstrous, and breeding occurs throughout the year although there is a peak in early summer. The number of young in a litter averages about two, and females produce from one to five litters a season; the survival-rate is low, nearly half the litters of 1946 disappearing before any members of them were trapped. An important character of the population, however, is that the number of adults remains fairly constant. Every month sufficient new rats appear to replace the old ones that vanish. There must always be some homeless rats seeking suitable houses, probably young ones that have never had homes of their own and old ones driven out by aggressive newcomers. A rat driven from a bad house by weather or other factors may be able to oust the owner of a better one.

These are but samples of the topics covered by this book, which deals with every facet of the life of the wood rat from the cradle to the grave. The researches recorded here are not only an important contribution to the study of mammals, but also a most interesting and intimate account of the life of a charming creature. Few species of wild mammal have been so closely studied or so thoroughly portrayed.

L. HARRISON MATTHEWS

MENTAL EPIDEMIOLOGY

On the Objective Study of Crowd Behaviour

By Dr. L. S. Penrose. Pp. vi+74. (London: H. K. Lewis and Co., Ltd., 1952.) 10s. net.

THE study of crowd behaviour has long been hampered by the lack of suitable quantitative methods of treating the data. The analytical approach of writers like le Bon and Freud, profound and illuminating as it has often proved to be, is not enough to establish a systematic science of social behaviour. Prof. L. S. Penrose's monograph represents an important advance towards this goal. His contribution to methodology is twofold: first, in suggesting new techniques of measuring the effects of the size of a group on changes of opinion among its members; and second, in quantifying the conceptic of a 'mental epidemic'. Let us consider these briefl in turn. Prof. Penrose takes as his fundamental un of measurement "a person characterised by possessir a given idea or potential reaction pattern". He mak the assumption that, in the type of group he is considering, the making of decisions and changes opinion among the group members may be looke upon as random fluctuations which are a functic only of group size. A comparatively small minorit of members who know their own minds can the control the decisions of the indifferent majority. I general, the power of a bloc vote diminishes only the square root of the number of indifferent membe The degree of control which a bloc of 5 exercises ov an indifferent 25 is the same as that exercised by bloc of 100 over 10,000. Given the size of the resolu minority and of the indifferent majority, an index the power of the minority can be obtained b reference to tables of the normal curve.

Prof. Penrose's second main contribution al involves the same fundamental unit of measureme and is based on an analogy he draws between physic and mental epidemiology, the growth and decline ideas in populations being described in terms epidemics and immunity. Corresponding to the thr factors distinguished by Stallybrass in physic epidemiology—namely, the infective agent, the mea of transmission, and the susceptibility of the expose population—so also in mental epidemiology the are: the quality of the idea; the visual, audito and other means of transmission; and the ment state of the recipient. Apart from the analogy wit single epidemics, analogies may also be drawn wit periodic epidemics and with persistent diseases. Th notion of mental epidemic is illustrated by referenc to phenomena of crazes, panic, religious outbreak politics, war and the general transmission of ideas i populations. Two examples are provided of quant tative representation: one, a craze in medical trea ment; and the other, voting in the America presidential elections over the period of a century The various ways in which the above factors may b influenced is discussed, in particular by isolatio which heightens receptivity to ideas, especially idea of suspicion. Isolation and suspicion thus produce vicious circle.

Prof. Penrose does not, however, glorify statistic analysis at the expense of clinical and experiment methods. Nor does he regard an epidemiologic model as the only useful one. He makes a numbe of enlightening remarks on the psychopathology c crowds. For example, he points out that, just as th individual mental patient is often unaware of hi sickness, so a crowd may be unaware of disturbanc in its behaviour, and "the recognition of the patho logical nature of many aspects of crowd behavio may prove a stabilizing factor in the development human cooperation".

It should perhaps be mentioned that the bo deals primarily with phenomena of collectiv behaviour, not with those phenomena of mutu interaction in groups which are increasingly occupyin the attention of experimental workers in soci psychology.

Prof. Penrose's suggestions are at once original an ingenious. They can be readily applied to experimental as well as to historical data, and they ma have an important bearing on such questions as th best size of national representation in a worl assembly.

JOHN COHEN

Stereoptics

An Introduction. By Leslie P. Dudley. Pp. 112. (London: MacDonald and Co. (Publishers), Ltd., 1951.) 15*s.* net.

THIS is a fascinating little book which should prove excellent relaxation for the physicist specializing in other fields and a good introduction for the serious student of the subject of stereoptics. The author, who is the originator of the apt term 'stereoptics' to describe the theory and applications of stereoscopic principles, particularly in the field of photographic optics, is also the technical director of Stereoptics, Ltd., London, and has played a large part in Great Britain in developing new processes of stereoscopy.

The book is chiefly concerned with the application of stereoptics to photography, cinematography and radiography, the first part dealing with general principles and processes which require some form of viewing device in order to perceive the stereoscopic effect, and the second part with a discussion of some of the more important auto-stereoscopic processes. An auto-stereoscopic photograph is one which exhibits a three-dimensional or solid effect without the use of a viewing device by the observer. Such photographs are now familiar objects, but it is good to be reminded that it was in 1902 that Frederic Ives filed his classic patent application for the first practical method, probably based on a suggestion of Berthier's, in 1896, of producing an auto-stereoscopic photograph. The various parallax stereogram and panoramagram processes and developments which have since been patented and used successfully are clearly described in an attractive and interesting, though technical, manner.

The author's own important contributions are modestly mentioned. The final chapter in the book deals with stereoscopic radiography, the use of which offers great potential advantages both industrially and medically. In this field the author can claim to be an authority, and his enthusiasm and optimism about the rapid advance and promising future of three-dimensional pictorial presentation should win over even the most sceptical of readers.

S. WEINTROUB

British Journal of Applied Physics

Editor: Dr. H. R. Lang. Vol. 2 and Supplement No. 1, 1951. Pp. v+370+viii+96+vi. (London: Institute of Physics, 1951.)

THE decision of the Institute of Physics in 1949 to commence a separate monthly periodical, the *British Journal of Applied Physics*, in addition to its *Journal of Scientific Instruments*, has been more than amply justified judging by the excellence of the contributions received and by the welcome given to the new *Journal* by physicists generally and more particularly by those employed in industry. In Vol. 2 the high standard set by the preceding volume is, if anything, surpassed.

In addition to the twelve monthly issues, containing special articles, conference reports and original contributions, the volume includes a supplement of some ninety pages on the physics of lubrication, in which the proceedings of the conference on that subject held in Manchester by the Institute and the British Society of Rheology during 1950 are reprinted. Four other conferences—on the aspects of fluid flow, spectroscopy, the development and application of Fourier methods in crystal-structure analysis, and the texture and structure of metals – form the subjects of special reports. Three of the nine special articles will be of particular interest to teachers of physics in technical institutions: these deal with the rationalized M.K.S. system of units, procedure in industrial physics and its implications for education, and impressions of a discussion on technical universities. The numerous original contributions, on the average four per issue, cover a very wide field, but nearly all have direct applications in industry.

The editor and advisory committee are to be congratulated for maintaining in these difficult times such a high standard, both as regards content and production.

Science and the Christian Man

By Charles E. Raven. Pp. 60. (London: S. C. M. Press, Ltd., 1952.) 4*s.* 6*d.* net.

THIS book consists of six broadcasts delivered by Canon C. E. Raven. It suffers from the unavoidable defects of all broadcasts—the covering of too much ground with too few words, of using insufficiently established premises and of leaving a multitude of loose ends. Such a book should be regarded as a provoker of thought rather than an authoritative manual. All will agree with the author that the Christian man cannot say no to science, which is a great achievement of the human spirit, and from which the man of to-day can scarcely stand aside: but the treatment of the relation of science to the beliefs of the Christian is less satisfactory. Canon Raven dismisses almost all the miraculous element in the Christian evidences, and indeed seems to select for credence only such passages from the Scriptures as suit his views; modern churchmen who think as he does will doubtless find the book much to their minds. On the other hand, Roman Catholics take a more stringent view of the interpretation of the Scriptures in a fashion other than literal; consequently Canon Raven's book will, for them, miss the point. This said, the book is to be commended. Many things are finely said, and few will read it without discovering in it some new facet of the great problem it discusses.

F. SHERWOOD TAYLOR

The Southern Marches

By H. J. Massingham. (Regional Books Series.) Pp. xv+368+25 plates. (London: Robert Hale, Ltd., 1952.) 21*s.* net.

THE Southern Marches—the southern borderland between England and Wales—comprises the region between the Wye and the Usk, between the Bristol Channel and north Herefordshire. Apart from places like Monmouth, Tintern, Chepstow, Symonds Yat, Ross, Raglan and the Channel of the Lower Wye, these southern marches are little known. In this book the late Mr. H. J. Massingham set out to bridge this gap in knowledge, and he succeeded very worthily. The ground is surveyed not only topographically but also in such aspects of the region as its architecture, its agriculture and its atmosphere. Local 'worthies' are given generous attention, while issues arising out of the author's travels are freely ventilated. Occasionally Mr. Massingham's views, like his prose, are extravagant, but these merely serve to accentuate the virility of a book which those who know and love the Southern Marches will treasure for years to come. "The landscape between Tintern and Chepstow" will indeed "continue to operate as tho' Paradise had never been lost". T. H. H.

CHAUCER'S ASTRONOMY

By Dr. DEREK J. PRICE
Christ's College, Cambridge

A FOURTEENTH-century astronomical manuscript in Peterhouse, Cambridge, was recently put forward* as a holograph draft of an unknown work by Geoffrey Chaucer. The tentative case has now been considerably strengthened by a photographic comparison of the handwriting with that of another suspected holograph in the Public Record Office. The similarity is striking in spite of a gap of seventeen years between the two specimens, and, taken with the linguistic and circumstantial evidence, it poses a problem which it is difficult, if not impossible, to answer without accepting Chaucer as the author of this "Equatorie of the Planetis".

A certain amount of interest in the text arises from its providing a new example of Chaucer's prose, for the first time unsullied by scribal perversion, and there is also the sentimental regard that one must have for a work in the poet's own hand. Two other aspects demand attention from the historian of science: What light is shed on Chaucer as a scientific writer, and what light is shed on medieval astronomy?

Chaucer's writings supply all the information we have about his interest and participation in scientific activity, and any comparative study is hindered by the fact that the interesting astronomical literature in Middle English has not been accorded the scholarly attention given to the Latin writings. From the frequent astronomical allusion in the "Canterbury Tales" and in his other works, it is clear that Chaucer was very well grounded in the "Almagest" of Ptolemy, and was competent as an observer and calculator. More certain evidence is provided by his "Treatise on the Astrolabe", written in 1392, and still to-day the best work in the English language on this extremely important medieval instrument which served both for observation and as an ingenious calculator for determining the positions of the stars at any time.

It is apparent that for astrologer and astronomer there is a complementary problem of finding the positions of the planets at the same time, and indeed in the Prologue of the "Astrolabe" we are told that such a section is to be included. The extant manuscripts, however, give only slightly more than two of the promised five portions, and we therefore possess only the sections on the astrolabe itself, with a little additional matter.

The new "Equatorie of the Planetis" together with its accompanying sets of astronomical tables go far to providing these missing sections. It seems as if Chaucer first wrote his table of contents and then modified his plan as the work proceeded—a technique that is also to be found in the "Canterbury Tales". As with the "Astrolabe", he was working from a Latin translation of an Arabic original, and if we are to judge by the frequent errors and corrections, and the large sections which have been struck out as erroneous, it must be admitted that an increase in complexity towards the end of the text led finally to the abandonment of the matter. The writer adopts the same personal and repetitious (but pleasant) tone of elementary instruction as in the "Astrolabe", and it is not surprising that he should ultimately fail when describing the finer detail of a topic which held a position similar to that of the theory of relativity in the first quarter of our present century. We can only conjecture how much of the failure was due to impossibility of simplification, and how much to imperfect understanding—certain errors show that the latter factor was not altogether wanting. On the other hand, original observations and computations show that he was not just translating or plagiarizing from an already existing work, but attempting a bold and popular account of an instrument which he considered important. He speaks of his own instrument and comments on its being smaller than would be desirable.

On the whole we get the impression that, although Chaucer did not attain the standard of coeval professional astronomers, he was nevertheless thoroughly well-schooled and competent. Aided perhaps by personal contact, he must have been abreast of the tremendous intellectual activity of the astronomers at Merton College, Oxford, who had made England pre-eminent in that field of learning during part of the thirteenth and fourteenth centuries. The existence of this second major piece of scientific writing also causes us to wonder whether Chaucer may have spent more of his later years in treating other technical subjects in the vernacular.

The new manuscript volume commences with some long sets of tables and then proceeds to describe the construction and use of an instrument which employs these tables for determining the position of the planets in the zodiac at any given time. It does this by simulating the geometrical construction required by the Ptolemaic theory, with its system of eccentric deferent circles and epicycles. The several constants of each planetary orbit are marked, once and for all, on the 6-ft. diameter board and ring of the *equatorie*; then two angles, each of the form $\theta = \theta' + \omega t$, are laid off on the instrument, and the position of the planet may then be read on the graduated limb.

The ingenious character of this particular form of equatorium, as opposed to all other reported varieties, lies in making the centre of the instrument represent the point (Aryn) at the centre of the earth, while permitting one standard-sized circle to serve as the deferent of all the planets. The very existence of such an instrument serves as confirmation, if such be needed, that the professional astronomer regarded the Ptolemaic system as a mathematical model, and not as the arrangement of material crystalline spheres described in more popular tracts. The construction of a facsimile of Chaucer's instrument has shown that results may be read to an accuracy of about five minutes of arc, and to this order of fineness the Ptolemaic theory serves well. In spite of widespread belief to the contrary, the Ptolemaic and Copernican planetary theories are almost identical in their mathematical consequences, and must give similar results for latitudes and longitudes and changes in apparent brightness of the planets. Copernicus modified and improved the theories of the moon and Mercury and threw new light on the system as a ole by considering motion relative to the sun, but s does not bring any new principles or accuracy his basic mathematical theory.

---

* *Times Lit. Supp.*, Feb. 29 and March 7, 1952

The astronomical tables used by Chaucer are based that version of the "Alfonsine Tables" which was entually published in Venice and Paris (first ition, Venice, 1483). At least three different forms these tables are known, the present one being tinguished by the use of *signa physica* of 60° tead of the more usual *signa communia* of 30°. It also noted for the tabulation of variables to ten agesimal places instead of the maximum of four five places that are demanded by the accuracy of observations on which they are based, and to ich other versions of these tables are restricted. ch excessive zeal in computation could not have en of much use in the Middle Ages (it corresponds an order of accuracy of about 1/1,000 sec. in 00,000 years), but it is invaluable now as providing mistakable evidence for reconstructing the prosses, approximations and assumptions used in the ginal calculations. One result of this analysis is show that their 'bad' value of precession, one volution in 49,000 years, does not refer to precession the modern sense, but to the calender error introced by the assumption that the (solar, tropical) year is actly 365¼ days. This is, of course, the error that now corrected by dropping three intercalary days four hundred years, that is, 365¼ days or one volution in 48,700 years. It accounts for just er half the true precession, the remainder being owed for by making the sphere of fixed stars cillate ± 9° with a period of 7,000 years, this being e 'trepidation' introduced by Thebit.

The form of these planetary tables is responsible r the invention and use of such equatoria as that scribed by Chaucer. The Ptolemaic theory is well apted to the calculation and explanation of specific ses and limiting examples (such as the location and agnitude of retrogradation), but it is not at all nvenient, even with the best tables then available, r the routine calculation of planetary positions—ch as were required for horoscopes and for practical tronomy. One can, it is true, make very good proximations as Ptolemy himself did; but medieval holars much preferred an exact solution. It would ve been possible to draw up a complete calender computed positions for, say, the next hundred ars, but before the era of the printed book this was expensive and wasteful procedure. Alternatively e could make use of the fact that after some propriate period the anomalies of any one planet turned quite closely to a previous position, and this owed the computation to be restricted to one such cle only. Such sets of cycles forming "perpetual hemerides" were calculated by Azarchiel in the venth century and continued in use until the mulative errors of several cycles made them viously invalid.

The only remaining possibility was to retain the ll theory for exact calculation, but to substitute ecise geometrical construction for intractable gonometry. The earliest examples of such means distinct from ancient demonstration devices milar to the orrery) seem to be due to Azarchiel d Ibn al-Samh in the eleventh century. Going nd in hand with the re-making of tables, these orks were translated by the Alfonsine *atelier* and lapted for use with the tables made during 1263–72. hereafter it seems to happen frequently that a new t of tables, or a revision, is accompanied by a *Canon* describing some type of equatorium. We have accounts of instruments designed by John of Linières and by Profatius, and one is ascribed to John Campanus of Novarra (who was probably only the translator); there is also the "Albion" of Richard of Wallingford, which was improved by Simon Tunsted and elaborated by John of Gmunden. Contemporary with that of Chaucer is a similar but more complete instrument described by the Iranian al-Kāshī, and finally, in 1540, the series of instruments culminated in the publication of the sumptuous "Astronomicon Caesarum" of Peter Apian, who made the ultimate improvements of dispensing with the auxiliary tables and separating the various functions of the instrument so that it could be reduced to a set of paper volvelles bound into a book.

The "Equatorie of the Planetis" provides us with the only account in English of this device, and focuses attention on an important medieval astronomical instrument the very existence of which had been almost forgotten.

SPORE CONTENT OF THE ATMOSPHERE NEAR THE GROUND

By P. H. GREGORY

Rothamsted Experimental Station, Harpenden, Herts

A KNOWLEDGE of the composition of the spore flora of the air is important to agriculture because it includes crop pathogens, and to medicine because of the occurrence of respiratory allergens. Yet its composition and concentration remain undetermined because there has been no suitable quantitative method of measurement. The population of air-borne particles of plant or animal origin, which will here be called the air 'spora' (taking the Greek σπορά as a word of similar usage to 'flora' and 'fauna'), contains spores and pollens of various shapes ranging in size from 100 μ in diameter for some tree pollens down to 3–5 μ with some of the smallest fungus spores.

Methods in use for routine survey[1] generally depend either on exposing sticky surfaces (such as horizontal or vertical glass slides) and counting the spores deposited, or on exposing Petri dishes containing culture medium and counting the colonies developing after incubation. Data from these surface traps have been interpreted on the tacit assumption that the relation between the number of particles suspended in the air flowing over the surface and the number deposited on the surface is known. In wind-tunnel experiments[2] it was found that spore concentration is only one factor in determining deposition, and that particle size, wind speed and the dimensions and orientation of the trap surface can have an overriding effect on deposition. In still air a horizontal surface may sample the air according to simple rules. When the air is moving, however, the windward surfaces of the trap, such as the edges and supports, or even the trapping surface, deflect the air-stream, and also deflect the spores themselves to an extent varying with their momentum and hence with their ability to slip out of the deflected air-stream and continue their trajectories. The efficiency with which a sticky surface removes spores from the oncoming column of air varies with the speed of the wind, and the deposit may alter very greatly with no change in concentration of the air spora. Records from surface traps are therefore difficult to interpret in terms of spore concentration per unit volume, as the wind speed at the time of deposition is usually unknown. The fact that they actually measure spore deposition on the particular surface in use and not spore concentration in the air is often ignored.

For efficient sampling of the air spora an apparatus is required which draws in a known volume of air without altering its spore content, removes all particles over the 2–100 μ size range, and leaves them in a form in which they can be examined, counted and classified.

The slit-sampler[3] of Bourdillon, Lidwell and Thomas is well adapted for volumetric sampling still air for those moulds and bacteria which grow on artificial media. Like earlier equipment, however, it is less suitable for sampling fungi and pollens from moving air out of doors. I have used the cascade impactor designed by May[4] for sampling aerosols in the field and have found it well suited for volumetric sampling of the outdoor air spora for visual inspection under the microscope. When used in the field a fin directs the orifice of the cascade impactor into the wind. A source of suction is required to draw air through the orifice, behind which is a sticky slide where the larger particles are impacted. The air is then accelerated by being drawn through three successively smaller jets each impacting on a separate slide. The catch is thus fractionated into four size-groups and deposited in narrow bands on four slides which can be mounted for microscopical examination, or removed for culture if desired. If the orifice is to collect all spores in the sampled air the speed of intake through the first jet should be adjusted to the speed of the wind; but deviations from 'isokinetic' sampling are small except for large spores. The impactor retains approximately 80-100 per cent of all spores collected by the orifice, down to about 1 μ diam.

For continuous records the cascade impactor suffers from the disadvantage that the deposit becomes too dense unless the slides are changed frequently, and for continuous operation in the open air the Hirst automatic volumetric spore trap[5] is more convenient. In this trap, which is based on the second jet only of the cascade impactor, a clockwork mechanism moves the slide past the orifice at 2 mm. per hour, so that the spores entering the trap are deposited on a 24-hour trace 48 mm. long, and diurnal changes in the air spora can be determined with an error of about ± 1 hour.

In the experiments at Rothamsted, the cascade impactor (Casella's model) has been used in several series of six consecutive four-hour runs at a height of 2 m. in the open air in dry weather. The concentration of spores and pollen of different types as directly measured reveals an air spora differing markedly from that indicated by surface traps.

Beginning at 09.00 hr. G.M.T. during each of the 24-hour periods chosen, sets of four slides were exposed in the cascade impactor for six four-hour periods, with a sampling rate of 10 litres per minute as measured by a 'rotameter', giving a total volume of 14·4 cubic metres in twenty-four hours. After mounting, the slides were scanned unstained under the oil immersion objective and the spores classified nto convenient morphological groups. Identification uld sometimes have been carried further, but with re characters alone specific identification is seldom possible. The concentrations during a typical 24- series are shown in the accompanying table.

COMPOSITION OF THE DRY AIR SPORA AT ROTHAMSTED, JUNE 10–
1952
(Number of spores per cubic metre of air)

Spore group	Period (G.M.T.) 9–13 hr	13–17 hr.	17–21 hr.	21–1 hr	1–5 hr.	5–9 hr.
Unidentified minute hyaline spores	2,340	2,510	2,550	3,120	4,700	2,25
Cladosporium	3,280	5,030	1,770	2,850	1,220	1,98
Hyaline basidiospores	1,170	610	530	1,110	7,010	4,38
Grass pollens	1,030	2,120	1,210	615	230	48
Unclassified	240	430	260	780	330	43
Ustilago 'avenae'	350	680	420	520	230	4
Erysiphe conidia	580	230	100	60	40	1
Other pollens	170	210	90	90	30	7
Coloured basidiospores	0	40	15	220	180	10
Uredospores	15	40	30	7	0	1
Total	9,175	11,900	6,975	9,372	13 970	9,83

The first slide, with the largest size-fraction, co tained most of the pollens. The catch in the tab represents the concentration of grass pollen at t height of the season in a position 2 m. above t ground with no great quantity of grass within hundred yards. Uredospores of *Puccinia* spp. we not abundant in spite of the presence of whe heavily infected with *Puccinia glumarum* within s hundred yards upwind of the trap. Conidia of t powdery mildew, *Erysiphe graminis*, may have com from a field of heavily infected spring-sown bar about fifty yards from the trapping site. Mu greater concentrations of powdery mildew occurr later in the season.

The second slide, with the next smaller fractio contained a few of the types found on the first sli The records of *Cladosporium* illustrate the conce trations observed a few weeks before its season maximum. The spores of *Cladosporium* vary wide in size and degree of aggregation. Large clumps ma be found on the first slide, while the smallest individu spores often penetrate to the third slide. Spores *Ustilago avenae* type (including, no doubt, the morph logically similar *U. perennans* from wild grasses) al occur singly and in clumps of varying size, and for a substantial part of the dry air spora at this seaso Coloured basidiospores, mainly from the Agaricace and from the bracket fungus *Ganoderma*, also occurr but were only few in comparison with those found Rothamsted[6] in August and September 1951; b again they occurred predominantly at night. Sma numbers of spores of *Helminthosporium*, *Alternar* *Epicoccum*, *Botrytis*, *Polythrincium trifolii*, and various other smuts, formed a regular component the "Unclassified" group in the second fraction, b are not shown separately in the table.

The third slide contained minute hyaline spor some of which also occur on the second slide. T most interesting of these are minute hyaline basid spores, which were rare during the day, but reach the high concentration of 7,000 per cubic metre duri the early hours of the morning (exceptionally a co centration of ten times this value has been recor during the period 01.00–05.00 hr.). Other evide suggests that a large proportion of these are basid spores of the mirror yeasts, *Sporobolomyces* sp Apparently these basidiomycetous yeasts, inhabitin the surface of leaves, discharge their basidiospor into the air in immense numbers when moist wit dew, and at this time they constitute a major elemen of the dry air spora. Soon after dawn, as the da me spora becomes re-established, they disappear ysteriously. Petri dishes (9 cm. diam.) of medium xposed horizontally for ten minutes at the beginning each period during a similar series of tests on ly 24–25 gave 1, 7, 5, 4, 5 and 28 colonies respect- ely of *Sporobolomyces*. Their occurrence as a gnificant element of the air spora does not appear have been recorded hitherto; but Mr. Merfyn ichards (*in lit.*) informs me that this observation nfirms earlier experiments in which he trapped rge numbers of *Sporobolomyces* on plates exposed uring the night at Llandough Hospital in August 951.

Another group of minute hyaline spores in the cond and third fractions consisted of rod-shaped, inted or septate spores. The smallest of these could ssibly be confused with bacilli; but bacteria would ot be expected to occur singly, free in the air, in rge numbers, though some Actinomycetes might do . Some of this fraction may consist of ascospores, ut its composition is at present obscure and merits rther investigation because of its potential interest plant pathology. Some structurally characterless inute hyaline spherical spores have probably been verlooked and omitted from the count.

The fourth fraction is free from plant spores, but ontains a copious deposit of smoke particles. The bsence of spores among the smallest particle fraction n the fourth slide shows that all particles in the size- ange of plant spores are deposited on the first three tages, and that the cascade impactor can be relied pon to give a reasonably undistorted picture of the ntire air spora. The emptiness of the fourth slide ives confidence in the end point.

The cascade impactor thus allows a preliminary isual examination of the whole air spora, and shows hat the smaller spores make up a very large pro- ortion of the total number present. This was not hown by the surface traps in general use, which lthough giving some information of the relative bundance of large spore types at different times, are eavily weighted in favour of larger spores. For a omparison of the relative concentration of different pore types at any time the data given by surface raps can perhaps not unfairly be described as a garithmic lie.

The species making up the smaller size fraction of he dry air spora are largely unknown, but transient louds of small hyaline basidiospores occur during the ight in high concentration. Well-marked fluctuations ith time of day and changes in weather, differing ith different species, are also observed, and have een studied in greater detail in both dry and damp r by Hirst[5,6], using the more convenient automatic lumetric spore trap. Simultaneous comparisons in e field between the cascade impactor and the Hirst ap have shown that the models of the latter at esent in use retain spores of all sizes with a higher ficiency than previously expected.

The greater part of the solid material larger than μ suspended in the atmosphere in dry weather under ur conditions consists, not of inorganic dust, but of nt spores of one sort or another. It is clear that reasing knowledge of the air spora depends on the der use of power-operated sampling equipment such the cascade impactor for spot sampling, or the irst automatic volumetric trap for continuous cords. The results obtained at Rothamsted show r the first time that a quantitatively complete icture of the air spora can be obtained. The pos- bility is opened up of applying these methods at other times and in other places and of attempting to correlate the findings with the occurrence of crop diseases and of respiratory allergy.

THE NORTH OF ENGLAND INSTITUTE OF MINING AND MECHANICAL ENGINEERS

By Prof. GRANVILLE POOLE

King's College, Newcastle upon Tyne

An event of great historical interest to the mining industry in Great Britain occurs this year, for the members of the North of England Institute of Mining and Mechanical Engineers are celebrating the hundredth anniversary of its formation in 1852.

Most fortunately, the first president—Nicholas Wood—was a man of outstanding ability and fore-sight. He was born in 1795 and in early life was thrown into the society of George Stephenson, to whom he became an assistant in that series of persevering experiments which at last resulted in the steam locomotive. Mr. Wood made the drawings from which, under its inventor's instructions, the Stephenson safety lamp was constructed. Mr. Wood also accompanied Stephenson to Darlington to engineer the Stockton and Darlington Railway. He wrote a book on the "Establishment and Economy of Railways" in 1825.

On July 3, 1852, a meeting of coal owners and 'viewers' in Newcastle resulted in the formation of a Society called "The North of England Society for the Prevention of Accidents"; but at a second meeting the title was changed to "The North of England Institute of Mining Engineers". As mining involved much engineering, it was considered desirable to include engineers among its members, and the title was later again changed to its present form.

Mr. Wood's contributions to the *Transactions* of the Institute included articles on the relative value of steam jets and furnaces to increase the ventilation of mines; on safety lamps; on the conveyance of coal underground; on sinking shafts through the water-bearing magnesian limestone and on the geology of the Northern Coalfield in Great Britain. He also paved the way for the establishment of a collegiate institution "for the cultivation, improvement and the teaching of mining science".

Nicholas Wood's inaugural address displayed that high sense of professional obligation and resolve which activated the original members and which resulted in the growth of the stature of the Institute being recognized in 1876 by the grant of a royal charter by Queen Victoria. The following tribute is to be found in this charter: "that it has during its existence of a period of nearly a quarter of a century steadily devoted itself to the preservation of human life and the safer development of mineral property, that it has contributed substantially and beneficially to the prosperity of the country and the welfare and happiness of the community".

By this time the Institute membership had grown to more than eight hundred, and in terms of the charter "included a large proportion of the leading Mining Engineers in the United Kingdom". Indeed, a review of the list of members reveals that membership was beginning to be world-wide, and the Institute was becoming a clearing-house of technical information on coal mining in many countries.

The example set by the North of England was followed by the formation of mining institutes in other coalfields, and the North of England Institute played a leading part in the establishment in London in 1889 of the Institution of Mining Engineers—now a federation of eight mining institutes from all parts of Britain.

Many historic papers have been read at the meetings of the North of England Institute. In the early years, when many disastrous explosions occurred, particular attention was paid to the ventilation of mines. John Buddle, the 'father of English mining', realizing the possible danger of using a furnace to assist in the natural ventilation, invented an air pump—the forerunner of the modern fan. A series of papers by J. J. Atkinson on the principles of mine ventilation laid the foundation of modern ventilation technology. Though Humphry Davy had improved the then safety lamp, his 'Davy lamp' was proved to be unsafe in certain circumstances and improvements were gradually brought about.

Many valuable papers on methods of working and the control of the strata are to be found in the *Transactions* of the Institute. With regard to methods of working coal seams, as the very shallow seams became exhausted it became necessary to sink deeper shafts and to work a greater area from each shaft, and the first method of really underground working was evolved, namely, the room and pillar method of mining. G. C. Greenwell in 1852 wrote "A Practical Treatise on Mining Engineering" at a time when there was practically no literature on mining in the English language. The first edition was based on a series of lectures delivered at the Newcastle College of Practical Science—the forerunner of the King's College of to-day. In passing, reference may be made to a statement made by a prominent mining engineer in the United States of America to the effect that their modern method of working is based more or less on Greenwell's ideas.

The Institute had from time to time set up committees to study specific mining problems, and in 1924 "The Support of Workings in Mines Committee" was appointed to investigate the causes of falls and accidents due to falls. In 1930 the Committee was provided with funds by the Safety in Mines Research Board for the appointment of a full-time investigator. The reports of this Committee provide a comprehensive statement of the fundamental factors determining the behaviour of the strata in mining operations.

In 1948 the Northern Divisional Strata Control Research Committee of the National Coal Board was set up. The Committee has a membership representative of the Durham and Northern Divisions of the Coal Board and of the North of England Institute of Mining and Mechanical Engineers, including members of the staff of the Mining Department of King's College, University of Durham. In this way the Institute has been enabled to continue its contributions to its historic work in this field. This is an ideal combination of observation and experiment in mines, together with academic work in the University such as photo-elastic research on plastic mod of mine workings.

The early pioneers would have been astounded they could have listened to the most recent pap read at a meeting of the Institute, when successf experiments were described in the getting of co from very thin seams without any men on the worki face at all. Such is the progress made in t mechanization of mining operations.

With such grand traditions, it will not be su prising that the North of England Institute Mining and Mechanical Engineers is still very active engaged in research to secure the increased safe and health and well-being of those employed in t mining industry. In addition to the research me tioned on roof control and prevention of falls ground, there are committees on the lighting a ventilation of mines.

The research on lighting is being carried out wi the view, ultimately, of being able to predict t performance of any lighting fitting under any set mining conditions. The series of tests being done the moment are designed to investigate the effect shape of a mine roadway and the reflexion factor its walls and roof on the utilization factors. Th work is being done in the Mining Laboratories King's College, Newcastle upon Tyne, and tests a also being carried out underground so as to obtain continual correlation of results. A special photomet has been designed and constructed with which t spherical distribution of any source can be foun Investigations also cover the safety of fluoresce lamp units for use in gassy mines, and a se signalling system on longwall faces.

The immediate object of the research on ventilati is the formulation of rules and formulæ as the ba for the design of fan drifts.

The first meetings of the Institute were in t lecture room of the Literary and Philosophical Socie at Newcastle upon Tyne; but through the enthu iastic efforts of its members and with the co-operati of the coal owners, the present well-known home the Institute, Neville Hall, Newcastle upon Tyn was built and opened in 1872.

The beautiful Wood Memorial Hall Library a ideally arranged lecture theatre, together with t other offices provided, bear witness to the profession spirit aroused by the inauguration of the Institut and have done much to inspire succeeding generatio of mining and mechanical engineers in devotion the task of following the objectives so clearly set o by Nicholas Wood.

In order adequately to maintain this building a to ensure continuity in research, a Centenary Appe Fund has been opened, and it is hoped that t appeal will meet with generous response.

INTERNATIONAL SEAWEED SYMPOSIUM

AN international seaweed symposium, organi by the Institute of Seaweed Research, University of Edinburgh and the Scottish Mar Biological Association, with the assistance of co responding delegates from Australia, Canada, Chil France, Germany, New Zealand, Norway, Sou Africa, Spain, Sweden and the United States America, was held in Edinburgh during July 13–1 The symposium, which was the first of its kin attracted world-wide interest, and was attended by some 160 scientists and technologists from more than twenty countries and Colonial dependencies. Lord Bilsland, chairman of the Board of Management of the Institute of Seaweed Research, presided at the opening ceremony in the Zoology Department of the University of Edinburgh and offered a warm welcome to all the members. In his address in formally opening the symposium, Mr. James Stuart, Secretary of State for Scotland, considered that many of our present industrial and agricultural problems might be alleviated to a very appreciable extent by making better use of the hundreds of thousands of tons of seaweed growing naturally around our shores, whether by way of animal feeding-stuffs or in the many other ways which are being investigated by men of science in their present research programmes.

At the first session, which was devoted to 'Phycology", Dr. E. M. Burrows (Great Britain) opened the proceedings with a paper on "Intertidal Plant Populations with Special References to the Genus *Fucus*", in which she referred to the effect of habitat variation, genetical variation and hybridization occurring in *Fucus spiralis*, *F. vesiculosus* and *F. serratus*. Dr. D. de Virville (University of Paris) delivered a paper on "Algal Population Decrease on the East Coast of Cotentin", in which he discussed the main types of marine plants gathered for agricultural and industrial use from the Atlantic coast of France. The Fucaceæ (*Fucus vesiculosus*, *F. serratus* and *Ascophyllum nodosum*) are collected chiefly for manure, the Laminariaceæ (*Laminaria*, *Saccorhiza* and *Alaria* species) for the extraction of iodine, *Chondrus crispus* and *Gigartina mamillosa* for the preparation of gels, and *Zostera marina* as a packing or filling material. A progressive decrease of these plant growths, due often to excessive gathering, has been recorded in recent years, and Dr. de Virville suggested that more severe control of harvesting should be introduced in an effort to halt this serious depopulation.

Several papers were devoted to a detailed study of the seaweeds occurring in different parts of the world. Dr. E. Jaasund (Sweden) discussed the marine algæ of the north Norwegian coast-line, Dr. L. Bellon (Spain) dealt with the seaweeds of the Malagan coast, Mr. C. Primo (Spain) described the algal population of Spanish West Africa, and Dr. J. R. Nunn read a paper on the seaweed vegetation of South Africa. Contributions dealing with the purely botanical aspect of the marine algæ were given by Dr. P. Kornmann (Germany), who discussed the development of *Giffordia fuscata* (Zan), Prof. J. Feldmann (France) on the evolution of the female organs of the Florideæ, Dr. H. B. S. Womersley (Australia) on the *Macrocystis* species of southern Australia, Dr. T. Levring on the reduced forms occurring in the Swedish marine flora, and Prof. M. Chadefaud (France) on the staining techniques developed for the cytological study of the algæ. Dr. B. L. Moss (Great Britain) discussed the variation in chemical constitution occurring during the development of the Fucales, and emphasized the importance of giving accurate descriptions of any plant material submitted for chemical analysis. Mr. B. Grenager spoke on the surveying of the Norwegian seaweeds by means of the spring grab technique developed by the Scottish Seaweed Research Association.

"Algal Chemistry" was the subject for the second session, and Prof. T. Dillon (University of Galway) opened the proceedings with a lecture on "The Constitution of Some Seaweed Mucilages". He described the preparation and purification of a polysaccharide sulphuric ester from fruiting *Ascophyllum nodosum*, which contained one galactose to seven fucose residues and having one sulphate group attached to each monosaccharide anhydride unit. The galactan sulphuric esters from *Gelidium latifolium*, carragheen moss, *Furcellaria fastigiata*, *Dilsea edulis* and *Dumontia incrassata* were also discussed. Dr. F. J. Coll (Eire) dealt with the constitution of floridean starch extracted from *Furcellaria fastigiata* and *Dilsea edulis*, and presented evidence to show, from methylation and β-amylolysis studies, that at least 50 per cent of the molecule consists of α-D-glucopyranose units linked through carbon atoms 1 and 4 as in ordinary starch. The quantitative liberation of carbon dioxide from uronic and polyuronic acids, such as alginic acid, when heated at 255° C. in the absence of any catalyst, was discussed by Dr. A. S. Perlin (Canada). The evidence suggests that the reaction is a true decarboxylation, and it has been employed for the analysis of several polyuronides, such as oxidized cellulose and starch. Dr. R. W. Watson (Canada) read a paper on "The Molecular Weight of Algin as determined by Sedimentation and Diffusion", in which the weight average molecular weight of four samples of sodium alginate ranged from 32,000 to 165,000, and appeared to be linearly related to the intrinsic viscosity. The variations in chemical composition among individual *Laminaria digitata* plants, collected at the same time and from the same habitat, were described by Mr. A. Haug (Norway), who found large individual variations in the dry matter and ash content with smaller variations in the alginate content. He emphasized the importance of these results in recording analytical data for the brown algæ. The alginate, ash, mannitol, laminarin, combined fucose and iodine content of various South African Phæophyceæ was dealt with in a paper read by Dr. J. R. Nunn, while Mr. C. W. Bonniksen (Great Britain) described the various uses of alginates and alginate materials in medicine and surgery. The nitrogenous constituents of the marine algæ were reviewed by Dr. E. Gordon Young (Canada) and Dr. G. T. Young (Great Britain). Algal peptides and proteins are difficult to extract, relatively strong alkali being required to extract 50 per cent of the total nitrogen. Dr. G. T. Young described the nitrogen distribution in various common brown seaweeds between volatile base nitrogen (chiefly ammonia), nitrate-nitrogen and residual Kjeldahl-nitrogen, and pointed out that the α-amino-nitrogen after hydrolysis was invariably less than the residual Kjeldahl-nitrogen, due probably to decomposition of the amino-acids in presence of carbohydrates. Acid hydrolysates of *L. saccharina* and *A. nodosum* contained the following amino-acids: glycine, alanine, valine, leucine, isoleucine, aspartic acid, glutamic acid, serine, threonine, proline, phenylalanine, lysine and a trace of arginine. Mr. L. E. Ericson (Sweden) spoke on the occurrence of vitamin B_{12}, folic acid, folinic acid and various amino-acids in different brown and red seaweeds from the Baltic and North Seas; the content of vitamin B_{12} in some algæ appears to be comparable with that of liver.

At the session with "Utilization" as the subject, Mr. R. W. Moncrieff (Great Britain) reviewed the present uses of alginates in foodstuffs, textiles, toilet goods, paints and engineering; recent developments include a washable flame-proof fabric and table jellies that set in hot weather. The expansion of the seaweed industry has hitherto been limited not by any shortage of seaweed or difficulty of extracting alginates, but by the limited number of known uses for seaweed derivatives, and the development of the alginates is at present being actively studied. The utilization in the United States of agar and carragheenin, the two chief gelling agents extracted from the red algæ, was discussed by Mr. E. C. Jertson (United States), and Dr. D. C. West read a paper on "A Survey of Certain Seaweeds of Commercial Importance in South West Nova Scotia". The survey revealed the presence of approximately 200,000 tons of rockweed, 900,000 tons of *Laminaria* spp., while in 1950 almost 8,000,000 lb. of *Chondrus* were harvested. Recolonization of these species was also discussed. Industrial applications of the seaweeds in Spain were dealt with by Dr. J. Aravio-Torre, who spoke of the rapidly increasing production of agar from 1944 to the present time, production in 1951 amounting to some 62,000 lb.; the brown seaweed industry, however, has not grown to the same extent. The session on utilization was concluded by Mr. C. J. E. Hand (Great Britain), who described the results of feeding various seaweed meals to laying hens: the introduction of 10 per cent of seaweed meal into the basal ration, although causing increased water consumption, did not produce any ill-effect upon egg production, egg weight and shell weight in small-scale trials of 100 days involving groups of four birds. When 15 per cent of the basic ration, however, was replaced, water consumption was further increased, and live-weight and egg production decreased.

The final session, entitled "World Seaweed Resources", was introduced by Dr. F. N. Woodward (director of the Institute of Seaweed Research), and the following spoke on the seaweed resources of their respective countries: Dr. H. B. S. Womersley (Australia and New Zealand), Dr. D. C. West and Dr. G. M. Shrum (Canada), Mr. E. C. T. Holsinger (Ceylon), Prof. H. Etcheverry (Chile), Dr. S. Lund (Denmark), Mr. D. T. Flood (Eire), Prof. J. Feldmann (France), Prof. C. Hoffmann (Germany), Mr. F. T. Walker (Great Britain), Dr. J. R. Nunn (South Africa), Dr. L. Bellon (Spain), Dr. T. Levring (Sweden), and Mr. G. W. Anderson (Zanzibar). Papers from the following authors, who were unable to attend the symposium, were read by title: Prof. T. Rayss (Israel), Dr. S. Suto (Japan), Prof. T. Braarud (Norway), Dr. G. T. Velasquez (Philippines), and Drs. K. S. Pillai and N. S. Varier (Travancore–Cochin).

Many members contributed to the discussion on each group of papers at the end of the various sessions, and a résumé of these discussions, together with abstracts of the complete set of papers presented and read by title, will appear in the "Proceedings" of the symposium, copies of which should be available before the end of this year. Dr. M. Knight (Great Britain), Dr. T. Levring (Sweden), Prof. C. G. C. Chesters (Great Britain), Dr. E. Gordon Young (Canada), Prof. E. L. Hirst (Great Britain), Mr. E. C. Jertson (United States) and Dr. F. N. Woodward (Great Britain) presided at the various sessions.

There were three excursions connected with the symposium. On July 13, a joint meeting with the British Phycological Group was held at St. Andrews, where members and their friends visited the Gatty Marine Laboratory and were given ample opportunity of studying the marine flora of that part of the coast. On the afternoon of July 15, members visited the Institute of Seaweed Research, Inveresk, Midlothian, to inspect the laboratories and workshops. Mr. Philip Jackson, deputy director of the Institute, gave a brief description of the different methods developed for harvesting sublittoral brown seaweeds, and on the morning of July 17 demonstrations of this equipment were held at Dunbar and Fisherrow.

There were also three social events held during the evenings. On July 14, delegates were provided with an opportunity of meeting in very pleasant circumstances at a cocktail party given by the Secretary of State for Scotland, while on July 16 the Magistrates and Council of the City of Edinburgh showed their interest in the purpose of the symposium by holding a reception in honour of its members in the City Chambers; in the absence of the Lord Provost members were welcomed by Senior-Bailie James Campbell, and Mr. E. C. Jertson replied for the visitors. On July 15, a dinner was held in the hall of the Royal College of Surgeons, where the principal speakers were Dr. F. N. Woodward and Sir Alexander Gray, professor of commercial and political economy and mercantile law in the University of Edinburgh.

Dr. T. Levring expressed the feelings of members when, at the closing session, he spoke of the success of the symposium, not only from a scientific but also from a social point of view. He suggested that the next symposium should be held in Norway three years hence, and this motion was very cordially supported.

E. T. DEWAR

NEWS and VIEWS

Commonwealth Scientific and Industrial Research Organization: Mr. G. A. Cook

MR. G. A. COOK is retiring from the post of secretary of the Commonwealth of Australia Scientific and Industrial Research Organization, after thirty years with the Organization and its predecessors, the Institute of Science and Industry and the Council for Scientific and Industrial Research. Mr. Cook graduated at the University of Melbourne with first-class final honours in science and in mining engineering. After service in the First World War, he worked with Sir Edgeworth David collating geological information from the French and Belgian Geological Surveys, and on his return to Australia undertook research in several phases of the mining and metals industries. When Mr. Cook joined the Institute of Science and Industry as scientific abstractor in 1922, there were only two people with a scientific training on the staff. He has seen the growth of that Institute into the present Organization, with a total staff of more than three thousand, including eleven hundred scientists. In 1927 he was appointed assistant secretary to the Council for Scientific and Industrial Research, and for many years was also officer in charge of its Information Service. He succeeded Mr. G. Lightfoot as secretary in 1944. Mr. Cook has always kept in personal touch with all phases of the Organization's work, and his long service as an administrator has given him wide experience of science and its organization. He has taken a particular interest in making the results of scientific research available to industry both as an editor of scientific publications and as a writer of non-technical accounts for the general reader.

The administrative work of the Commonwealth Scientific and Industrial Research Organization will now be the responsibility of four senior members of the secretariat: Mr. F. G. Nicholls, secretary (general administration); Mr. G. B. Gresford, secretary (physical and industrial sciences); Mr. W. Ives, secretary (agricultural and biological sciences); and Mr. M. G. Grace, secretary (finance and supplies).

Agricultural Census in Iraq

THE first agricultural census to be undertaken in the Middle East is now nearing completion in Iraq. This census, organized and directed by Dr. K. G. Fenelon, who is Government statistician, will provide information much needed for the planning of developments made possible by the rapidly increasing revenues from oil royalties. The statistics now being collected relate to such matters as land utilization, and tenures, farm labour, size of farms, crops and the livestock carried on farms or owned by nomadic tribes. Special emphasis has been placed on the need for early publication, and already data for certain districts are available. The census is a nation-wide survey and has necessitated a farm-to-farm visitation by specially trained enumerators drawn largely from the ranks of teachers and college students on vacation. As the majority of the farmers are illiterate, the verbal information given by them has had to be entered on the forms by the enumerators themselves and, where necessary, translated into Arabic from Kurdish or Turkish. In taking the census, which began in June and is expected to be completed in November, many difficulties have had to be overcome, especially in those districts where land settlement is not yet completed or where the flocks of nomadic tribes have to be enumerated. Many of the farms and villages are far removed from any main road, and though motor transport has been used where possible, other means of transit, such as mules in the mountains, camels in the desert or small boats in the marsh-lands, have been employed to reach these more remote villages.

Nuffield Botanic Garden, London

WHEN the Nuffield Foundation moves into its new headquarters at Grove House, Regent's Park, London, a large part of the four acres of gardens in which the house stands will be made available by the Foundation to University College, University of London, for botanical research. The garden will be known as the "Nuffield Botanic Garden". In the first instance, research is envisaged which will deal with some of the genetical aspects of the taxonomy of native British species and also with the problems associated with intersexes in plants, under the direction of Dr. J. Heslop Harrison. It is expected that later developments may include both ecological and experimental studies of native species, particularly those of taxonomic and ecological interest. Botanists will note with appreciation this important extension of the interests of the Nuffield Foundation to the field of experimental taxonomy.

Television in Wales and Scotland

ON August 15, the Postmaster-General, Lord De La Warr, opened the new television transmitting station for South Wales at Wenvoe, near Cardiff, thereby completing the first stage of the installation of the British television network. At the present time, this station is operating with a 5-kW. transmitter, but it will be raised to at least ten times this rating as soon as possible. Two days later, the Scottish station at Kirk o' Shotts was brought into full high-power operation by the completion of the new vision transmitter supplied by Electric and Musical Industries, Ltd., which is capable of delivering 75 kW. into the aerial. The corresponding high-power sound transmitter, supplied by Standard Telephones and Cables, Ltd., has a carrier output of 18 kW. at 100 per cent modulation. These installations replace the low-power standby transmitters which have been in use since the Scottish television service was opened last March (see *Nature*, March 22, p. 482). When the corresponding high-power transmitters are completed at Wenvoe, Scotland and Wales (including the west of England) will have the most powerful television stations in Britain and, it is thought, in the world. The completion of these stations will bring the British television service within the reach of some 40 million people, or about four-fifths of the population of the United Kingdom.

Social Insurance and the Problems of Poverty

THE Beveridge report on social insurance and allied services in Great Britain defined freedom from want as the basic purpose of the social security scheme. A recent broadsheet issued by Political and Economic Planning (No. 344. "Poverty: Ten Years After Beveridge") examines the extent to which efficient and permanent defences against poverty have been built up in Britain in fulfilment of this purpose during the past ten years. Attention is focused principally on the information and methods available for giving a definite meaning to poverty and thus fixing a poverty standard which can be used both by investigators in charge of social surveys and by administrators in determining the level of social payments. In particular, an attempt is made to give a clearer meaning to the term 'subsistence minimum' and to indicate the steps involved in arriving at such a minimum. At present, insufficient information is available to enable a satisfactory subsistence standard to be worked out, although the proposed inquiry of the Ministry of Labour into family budgets, intended to supply facts for a revision of the index of retail prices, could supply much of the missing information. The use of family budget data is the only practical way, the broadsheet points out, of limiting the arbitrariness of judgments for items other than food, and there is a strong argument for adding a few specific items, such as postage, shaving and hairdressing, laundry, contraceptives, sanitary towels, certain subscriptions, soap and other cleaning materials, to the list of necessities usually adopted in a standard, on the ground both that they occupy a consistent place in family budgets and that 'by conventional standards' they are necessities. In the last resort, decisions must be based on contemporary views about the lowest living conditions that are tolerable in the community. Whatever policy of preventing poverty is adopted, a carefully determined subsistence standard is essential for its success.

Sociological Bulletin

THE first issue of the new journal of the Indian Sociological Society, entitled the *Sociological Bulletin* (1, No. 1; 1952. Pp. 88; from the Indian Sociological Society, Jamnalal Bajaj Nagar, Kurla Road, Andheri; Rs. 3, or 4s.), is given a characteristic flavour of its own by the essay it includes by Prof. D. P. Mukerji on "Sociology in Independent India". The subject has, he thinks, been ignored hitherto by the Government of India, and insufficient use has been made of sociologists in the drafting of legislation. Nevertheless, sociology can now be offered in the competitive examinations of the Union Public Service Commission, which will give it a new status. Still more important than this, however, the shaping of a new society in India depends in large measure on the intelligent analysis of social trends and, in particular, on what Prof. Mukerji terms "culture-assimilation", and this is one of the more important tasks for the Indian sociologist to accomplish. Prof. Mukerji and his colleagues see themselves as members of a society attempting to avoid domination by both American and Russian culture and civilization. American sociology is sometimes presented to the Indian scholar as "a scientific discipline to save the world from Marxism"; but Dr. M. N. Srinivas roundly declares in his article on "Social Anthropology and Sociology" that, for all their claim to be 'scientists', American sociologists implicitly, but none the less deeply, believe in the values of contemporary America. The Indian sociologist, therefore, appears to be embarking on an attempt to develop his own study in his own way, rejecting both the American and the Russian patterns. His colleagues throughout the Western world will watch his work with interest and sympathy.

Japanese Researches in Biophysics

The Research Institute of Applied Electricity, Hokkaido University, Sapporo, Japan, has followed up its first monograph, entitled "Theory and Application of High Frequency Phenomena" (see *Nature*, **167**, 102; 1951), by a second interesting monograph on "Some Researches on Biophysics" (Monograph Series No. 2; pp. 69; August 1, 1951). This latter publication, which is edited by Y. Asami, contains six articles: the first two are concerned with the effects of radiation on proteins, the next two with the methods of excitation of and electrical conduction along nerves, and the remaining two with physio-chemical problems. M. Wakabayashi and F. Kawamura describe what is probably the first reliable investigation of the effects of large doses (10^5–10^6 r.) of X-rays on the serum proteins. The chemical changes produced were examined, and the results obtained were compared with the changes produced by ultra-violet radiation or by heating. The rapid vapour-pressure method of determination of the water content of easily purified proteins, devised by K. Hirota and F. Kawamura, is the subject of the other article on proteins, and the results of the application of the method to gelatin and fresh muscles support Wakabayashi and Kawamura's work. The other articles deal with the following topics: the spike and dome potential observed in the oil/saline-water nerve model; study of the discharge pattern of Hering's sinus nerve and the excitation mode in the chemoreceptors of the carotid body; polarographic measurements of oxygen concentration *in vivo*; and dielectric absorption and anomalous dispersion of polar solutions.

Forest Taxation in New Zealand

In Information Series No. 11 of the New Zealand Forest Service (Wellington, 1950), Mr. M. B. Grainger discusses the question of forest taxation, a recurring problem which appears still to be far from settled, since opinions differ widely on what should be a fair burden to lay upon forests, the produce from which is essential to all types of the human race in one form or another, quite apart from industrial utilization. Private forests, especially commercially owned private forests, as apart from the Government forests, play an important part in the forest economy of New Zealand. As Mr. Grainger says, "The National Forest policy has always envisaged private forests playing a significant part in New Zealand's timber and wood economy and therefore the Forest Service has sought to encourage good standards of forest management". The methods of taxing forest land and forest operations have proved increasingly difficult during the past thirty years and have come in for a good deal of criticism, certain anomalies, not unknown in other countries, having become apparent. It must be obvious to all that a property like a forest cannot be looked at from the same point of view as a house or industrial buildings, or even a farm with its short-term growing crops, and so forth. The forests, even short-rotation crops of 15–20 years or so for firewood, paper pulp, etc., are not so easily assessed for taxation purposes. There is no doubt that excessive taxation based on inability to grasp the different growing conditions and the longevity of these conditions have been in the past, and are at the present day, a serious threat to the perpetuation of the forest in parts of the world where this maintenance is of the first importance to the population of the country concerned. Before he formed the opinion that contemporary tax practice in New Zealand is prejudicial to good forestry, Mr. Grainger visited a number of selected European countries. In this brochure taxation methods in Great Britain, Sweden, Finland, France and Norway are briefly dealt with, the various systems compared and then contrasted with those of New Zealand, and proposals made with reference to the latter country.

Planets and Sunspots

The third part of K. G. Meldahl's paper on "Tidal Forces in the Sun's Corona due to Planets", which has recently been published (pp. 14 of text, and pp. 16 of illustrations. Copenhagen: Berlingske Forlag, 1952), carries on the work of the other two parts, published in 1938 and 1949 respectively (see *Nature*, **144**, 726 (1939) and **165**, 301 (1950); and also **166**, 1058 (1950)). In Part 2 it was shown that a period of 308·52 years has a powerful influence on the vertical tides, confirmatory evidence of which was found in the observations of auroras and sunspots. It was also pointed out that the partial force periods of the sun include one of 22·38 years, which approximates to Hale's estimated period for the changing polarity of the spots, and in Part 1 it was suggested that the disturbance which caused the spots moved along the meridian plane or nearly so. It remains to be seen whether Hale's observations will confirm Meldahl's views. While Part 3 repeats some of the results previously obtained, it also contains many new features and includes a separate portion with sixteen illustrations. These show that there is a preponderance of meridional forces pointing towards the equator, with maxima at about 45° latitude, and it is suggested that there may be corresponding currents in the coronal gases, such currents being subject to similar centrifugal forces in addition to the ordinary forces due to the sun's rotation. A number of photographs of solar eclipses are reproduced for 1860–1901, and these show the diamond shapes in the corona with four cusps at 45° latitude, thus corroborating the meridional forces already referred to. Certain hydrodynamic phenomena—in particular the case of a fluid surrounding a rotating sphere—are outlined in two illustrations, and it is found that a number of configurations resembling those found on the sun are in evidence in the experiments. Disappointed with the lack of satisfactory explanations of currents n the corona, Meldahl has formulated a hypothesis—dmittedly rather speculative though partly based on bservational data—leading to his "Characteristic Curves" for the sun regarded as a centrifugal fan, and this is explained in two illustrations and also at ength in the text. Deductions with this hypothesis s a basis seem to explain a number of phenomena ssociated with eclipses of the sun at various times; t will be interesting to learn whether the hypothesis s supported by observations of the eclipse of February 25, 1952.

Research Developments by British Thomson-Houston Co., Ltd.

An interesting illustrated article appears in the May–June issue (23, No. 3) of *B.T.H. Activities*, in which Mr. L. J. Davies, the director of research, reviews the work of the British Thomson-Houston Research Laboratory during 1951. New materials for use at high temperatures and new glasses, including a new phosphate glass for sodium-vapour discharge-lamps and tellurite glasses of unusual properties, have been developed, and the work of the Physical Analysis Group has been expanded considerably. The creep properties of alloys for steam turbines and gas turbines have been the subject of special interest and study. Work on the applications of lead sulphide photocells has resulted in the development of an infra-red radiation pyrometer for the measurement of surface temperatures down to 150° C. Other instruments developed were infra-red photoelectric relays and a halogen vapour leak detector. Single-crystal germanium has received considerable attention, and a new *p*—*n* junction-type germanium rectifier capable of handling considerable power has been produced. Improvements have been made in valves for marine radar, and new glass toroids of reduced size but which allow full use to be made of the magnetic flux available have been devised for use in betatrons and proved successful. A 2-MeV. impulse generator has been erected in the heavy plant factory at the Company's works at Rugby. It incorporates specially designed aluminium electrodes which together with the generator form a standard of capacitance for use with impulse voltages up to two million. The article concludes with a description of some very interesting developments in electroluminescence and in lamps of the high-pressure gas and vapour, fluorescent, germicidal and other types.

Libraries of the University of Leeds: Report for 1950–51

The annual report of the librarian of the University of Leeds for the session 1950–51 (pp. 12; from the University; 1951) records a total of 337,787 volumes and 151,645 pamphlets in the collections at June 30, 1951. Accessions during the year totalled 14,435 volumes, 3,042 pamphlets and 25,883 parts of periodicals, a decrease of 8 per cent on the previous session. Catalogue additions totalled 47,774, an increase of 19 per cent; loans to readers, 78,358, an increase of 10 per cent; and inter-library loans totalled 1,294 books borrowed and 1,495 books lent, increases of 31 and 10 per cent, respectively. On a quinquennial visit on November 15, the University Grants Committee saw the Brotherton Library, and the Medical Sub-Committee the Medical Library. A revised list of periodical holdings in the Brotherton Library is being prepared for the British Union Catalogue of Periodicals, and when this list is complete, in about two years time, it may be published separately as a handlist of periodicals in the University Library. In view of the forthcoming revised edition of the Short Title Catalogue of English books, 1475–1640, a list has been prepared of the items in the Catalogue which are possessed by the Library and also of a few items possessed by the Library which are not in the first edition of the Catalogue. The use made of the Medical Library has further increased in spite of serious difficulties due to inadequate accommodation. The library of the Institute of Education moved in August 1950 to more commodious quarters in University House, and the Library of the Department of Textile Industries became a sectional library under the central library administration from September 1. A new departmental library was started during the session in the Department of French, and the Library of the Department of Adult Education and Extra-Mural Studies will be incorporated as a section of the University Library from the beginning of the next quinquennium.

Society for Visiting Scientists: Annual Report for 1951–52

The report of the Secretary of the Society for Visiting Scientists, to the fifth general meeting, on July 24, refers to the reduction from £4,000 to £2,000 of the grant from the British Council, necessitated by the reduction of the Government grant to the latter body. The task of raising a sum of £4,000 for the financial year, starting on April 1 this year, has been undertaken by the honorary treasurer, Prof. A. Haddow, mainly by an appeal to industry (from which £900 has already been received). The Society is now registered as a charity, and four organizations have already signed a deed of covenant with the Society. Some saving has been effected by the reduction of the Society's activities. With the co-operation of the Science and Engineering Department, the Student Department and the Welfare Department, an Overseas Science Students Association, with a membership of 120, has been founded to welcome postgraduate science students from overseas and to bring them into closer contact with the scientific life of Great Britain and with one another. This Association is affiliated to the Society for Visiting Scientists. Prof. A. V. Hill is succeeding Sir Harold Spencer Jones as president of the Society, which has a membership of 1,900, but the report emphasizes that membership of British scientific workers is not increasing as much as is desired.

Reference List of Cultures of Protozoa

The Society of Protozoologists is establishing a centre of information for available cultures of free-living and parasitic Protozoa and algal flagellates maintained in various laboratories in the United States and other countries. This system will relieve the scientific worker who has isolated, or is maintaining, the cultures of the need to give technical information every time that a culture is requested. Those who are willing to co-operate in the formation of this reference list and are willing to send cultures to other investigators should request from the Committee on Cultures of Protozoa a data card for each species that is being maintained in their laboratory. On each card pertinent information regarding the origin of the culture, procedures for maintenance, key references and other essential data will be entered. These cards will form the basis for an alphabetical file of species and a taxonomical cross-reference list. In addition, the card will indicate where the culture may be obtained. Upon request for a certain species, a photostatic copy of the master card will be sent upon payment of a nominal fee. This information will be made available to all who are interested in obtaining cultures. The chairman of the Committee on Cultures of Protozoa is Dr. L. Provasoli, Haskins Laboratories, 305 East 43rd Street, New York 17, N.Y.

U.S. National Science Foundation: Research Grants

THE National Science Foundation (2,144 California Street, N.W., Washington 25, D.C.) has announced the award of the final group of research grants, approved during the fiscal year which ended on June 30, in its programme for the support of basic research. This group consists of twenty-nine grants, totalling 263,535 dollars, for biological and physical sciences, and the fields covered are as follows: astronomy, chemistry, developmental biology, earth sciences, engineering, environmental biology, experimental psychology, genetic biology, mathematics, microbiology, molecular biology, physics, regulatory biology, and systematic biology. Altogether ninety-eight grants have been awarded during the past year, totalling 1,181,175 dollars, and these were distributed to sixty institutions in thirty-five States and Hawaii, the average grant amounting to 11,032 dollars for 1·9 years, or about 5,800 dollars a year. While grants were selected primarily on the basis of scientific merit, the Foundation is attempting in its programme for the support of research to encourage the development of research activities in smaller institutions throughout the United States. This policy is aimed not only at increasing the research potential of the nation, but also at improving the teaching of science at both the graduate and undergraduate levels. Application forms for both predoctoral and postdoctoral graduate fellowships for the academic year 1953–54 can be obtained after October 1 from the Foundation. Completed applications must be returned to the Fellowship Office, National Research Council, by January 5, 1953. The special examination for predoctoral candidates will take place at various places throughout the United States on January 31, 1953.

National Smoke Abatement Society

THE annual conference of the National Smoke Abatement Society will be held at Portsmouth during September 24–26 under the presidency of Alderman F. E. Tylecote, of Manchester, emeritus professor of medicine in the University of Manchester. The Des Voeux Memorial Lecture this year will be by W. R. Hornby Steer, standing counsel to the Society, on "Smoke and the Law". The programme includes reports on air pollution and cancer of the lung (Dr. Percy Stocks), prevention of domestic smoke (Dr. J. L. Burns), work of the Fuel Research Station (Department of Scientific and Industrial Research) on atmospheric pollution (Dr. E. T. Wilkins), a session on incentives for the prevention of industrial and domestic air pollution, and a discussion on pollution problems in the iron and steel industry, to be opened by Prof. R. J. Sarjant. Further information can be obtained from the Society, Chandos House, Buckingham Gate, Westminster, London, S.W.1.

Announcements

WE regret to announce the death, on September 1 of Sir Richard Gregory, Bart., F.R.S., editor *Nature* from 1919 until the end of 1938, aged eighty eight.

THE Medical Research Council has appointed D J. C. Gilson to be director of its Pneumoconiosi Research Unit at Llandough Hospital, near Penarth Glamorganshire. Dr. Gilson, who was formerl assistant director of the Unit, takes the place of D Charles Fletcher, who resigned on August 31 to tak up an appointment at the Postgraduate Medic School of London.

A JOINT Committee consisting of representative of the Royal Society and the University of Cambridg has appointed Dr. R. J. Eden, of the University Cambridge, to be Smithson Research Fellow, for fou years in the first instance, from October 1. Dr. Ede will work in the University of Cambridge on th theory of fundamental particles.

THE biennial Conference of the Oil and Colou Chemists' Association will be held at Eastbourn during June 3–5, 1953. There will be three technica sessions, each composed of three papers, which wi be under the general title of "The Optical Propertie of Films of Surface Coating Materials". These paper are being arranged by the Honorary Research an Development Officer of the Association, Mr. P. J Gay, Hangers Paints, Ltd., Stoneferry Works, Hull

THE tenth annual meeting of the Electron Microscope Society of America will be held at the Statle Hotel, Cleveland, Ohio, during November 6–8 Programmes and abstracts of papers are availabl from C. E. Willoughby, DuPont Experimenta Station, Wilmington 98, Delaware. Informatio about local arrangements can be obtained from Mrs Mary S. Jaffe, LDL-85, General Electric Company Nela Park, Cleveland 12, Ohio.

A NEW multiple fellowship for long-range investigations in synthetic organic chemistry, with genera emphasis on chemotherapy and in particular th preparation of compounds for combating viruses an tumours, has been established at the Mellon Institut of Industrial Research, Pittsburgh, by the firm Parke, Davis and Co., of Detroit. The leader of th research group is Dr. A. M. Moore, who is a specialis in the synthesis of potential drugs and in the classification of organic compounds, and with him are thre senior Fellows (Drs. R. S. Tipson, Alice G. Renfrew and M. S. Morgan) and one Fellow (Pauline C. Piatt) Several other scientific workers and assistants ar also joining the group.

WE have received from Messrs. J. E. Buck a Co. a convenient little map measure which will b very useful in measuring the distance of one's rout on a one-inch or smaller-scale map. The instrumen which easily goes in the vest pocket, is made plastic material covering metal wheels. It is set f a scale of one inch to a mile. This measure can obtained direct from the makers at 47 Brewer Stree Piccadilly, W.1 (5*s*., post paid).

ERRATUM. In the communication "Micro-spherica Aggregation of Barium Sulphate" in *Nature* o September 6, p. 423, by D. I. Stock, in column 2, line 3, for "of the spheres" read "of the barium sulphate within the spheres".

xternal) degree in natural science or engineering. His regular commission will be granted at the end of is second year at the College, and on graduation his eniority will be antedated to agree with that of an fficer who has passed through Sandhurst, his exact osition being determined by the class of honours btained in his degree. This scheme is open to hoolboys between the ages of 17½ and 19½, and to fficers or men between 18½ and 20½ already doing National Service. Officers who take advantage of this scheme are required to agree to serve as Regular officers for at least five years from the date of graduation.

This is additional to the normal mode of entry, via the Royal Military Academy, Sandhurst. The effect is that, by whatever channel an officer enters the army, he is given an opportunity of studying for a university degree in science or engineering; and even if on entry he is not in possession of all the requisite ualifications, he will find at Sandhurst an opportunity for further study to complete them.

In April, the Ministry of Supply sponsored a scheme for ten studentships for civilians, value £265 er annum plus fees, tenable for three years at the College. The holders of these studentships, which re awarded on school reports and a competitive nterview, are required to read for a London External pecial Degree in natural science or for the degree in engineering. The primary object of the scheme is to train young men for posts in the Government scientific service, and on graduation the student is xpected to enter the competition for scientific fficers and to accept a suitable post, if offered. This is the first time during its history of nearly a century that the College has opened its doors to civilians, and the large entry received for the first ten studentships showed that the prospect of life at a residential college in an attractive area of English countryside ppealed to many.

O. G. SUTTON

COUNCIL FOR THE PRESERVATION OF RURAL ENGLAND

ANNUAL REPORT FOR 1951–52

THE annual report for 1951–52* of the Council for the Preservation of Rural England again tresses the need for a dispassionate assessment of he country's national resources in land as a whole, ut records the view of the Council that the balance eeds to be redressed more in the direction of agriculture and the safeguarding and creation of amenity, in which other interests are encroaching unduly. Insufficient attention is also being paid to land eclamation in all its aspects and to the important roblem of restoration after exploitation. Such forms f exploitation as open-cast coal working should, in the Council's opinion, be terminated at the earliest ossible moment. The safeguarding and creation of menity, in fact, are receiving less and less consideration, whereas they should be one of the main purposes f planning legislation; moreover, while the requirements of the Departments of State are by law outside the control of the planning authority, something ther than mere consultation at departmental level is equired in assessing true priorities where the relative alues of land use on a national scale are concerned.

Much time is still occupied by the consideration of the land requirements of the Armed Services so as to ensure that evidence is provided on amenity and scientific grounds wherever appropriate. Settlement of the outstanding requirements is regarded as unlikely to give a total varying much from the present figure of 550,000 acres compared with the estimate of 619,000 acres of the 1947 White Paper. The report comments pointedly on the delays in announcing the results of public inquiries and on the little time allowed to the Council or the local authorities in submitting comments on the Services' proposals as compared with the extreme leisure in which the proposals are handled by government departments.

Further reference is made in this report to the question of mineral extraction, and particulars are given of some cases with which the Council has been concerned. The situation as regards electricity undertakings was described fully in last year's report and is regarded as unchanged, but the Council records its opinion that much more could and should be done to avoid disfigurement in rural areas. In regard to the administration of national parks, the Council supports the view of the National Parks Commission and endorses the Commission's stand against the schemes of the British Electricity Authority in the Snowdonia National Park. The problem of refuse disposal in rural areas has caused some difficulty, and examples of successful action by the Council are quoted.

The efforts of the Council and associated organizations succeeded in securing certain amendments to the Forestry Bill in Parliament which removed the misgivings caused by the original Bill's disregard of amenity, and the Rivers (Prevention of Pollution) Act, 1951, was likewise greatly improved during its passage through Parliament, by amendments sponsored by the Council through its representation on the Central Council for River Protection. All such achievements must, however, be considered in the light of the growing tendency to disregard amenity, which is stressed at the outset of the report, and of the precarious financial position of the Council, which requires at least four thousand additional annual subscribers of one guinea or more to provide a sufficient income for the current year.

SECOND INTERNATIONAL CONGRESS ON RHEOLOGY

IT will be recalled that the First International Congress on Rheology was held in Scheveningen, Holland, in September 1948 (see *Nature*, 162, 747; 1948). A Dutch Organizing Committee was responsible for the arrangements for the Congress, which was held under the auspices of the Joint Commission on Rheology, International Council of Scientific Unions. Dutch industry provided the necessary funds. It was generally agreed that the Congress was most successful.

With the approval of the Joint Commission, the British Society of Rheology is organizing a Second International Congress, to be held in Oxford during July 26–31, 1953. The headquarters of the Congress will be at St. Hilda's College; accommodation has also been reserved in other Colleges.

The programme will include an address by the president, Sir Geoffrey Taylor, and invited lectures from some half-dozen prominent rheologists. Mme. A. Dobry-Duclaux (Paris), Dr. P. Eggleton (Edinburgh), Prof. F. H. Muller (Marburg), and Dr. R. S. Spencer (Midland, Michigan) have already accepted invitations to lecture ; Prof. E. Forslind (Stockholm) has accepted provisionally ; a Dutch rheologist and perhaps one other are also being invited to lecture. There will be an open discussion on the international organization of rheology.

---

* Council for the Preservation of Rural England. Annual Report, 51–52. Pp. 50+4 plates. (From the Council, 4 Hobart Place, London, W.1, 1952.)

The Congress will cover the whole field of the study of the deformation and flow of matter, except such specialized subjects as have come to be regarded as branches of applied mechanics, such as the classical theory of elasticity and aerodynamics. Contributions to the Congress, which must not exceed 2,000 words in length (including space for figures), will be welcomed, subject to referee's approval, if received by the organizing secretary by December 1, 1952.

The Proceedings will be published in book form, and, since it is intended to circulate proofs of the papers at the Congress itself, contributions cannot be guaranteed inclusion in the Proceedings if received late. It will facilitate discussion if papers are written and delivered in English. If this is not possible, French or German may be used. Contributions cannot be accepted for publication unless one of the authors is present to read the paper personally or, in very exceptional cases, can provide a colleague from his own laboratory who is fully competent to answer questions in the discussions. Lantern slides may be shown. Speakers, other than the invited lecturers, will be strictly limited to about 15–20 min. in presenting their papers. The exact time available will depend on the number of contributions received and, if necessary, several programmes will be run simultaneously.

Invitations have been or are being sent to rheologists in all countries where it is known that rheological research is in progress. It is hoped that the Congress may provide an opportunity for an exchange of views for rheologists from all over the world. It is requested that, if any groups of rheologists have been inadvertently overlooked, they will make themselves known to the organizing secretary as soon as possible.

Arrangements will be made for excursions, visits to colleges, etc., during the Congress. The wives of rheologists are welcome. The fee for the Congress, including available preprints, and a copy of the final Proceedings, is expected to be about £4, payable before May 1, 1953. (The cost of board and lodging varies : in college, it is at present estimated at about £1 10*s*. per day, inclusive.)

Final application for membership of the Congress should be made on forms which will accompany the provisional programme. Provisional application, on forms now available from the Organizing Secretary, should be returned to him, if possible, by October 1, 1952.

The Organizing Committee consists of the following : Mr. A. G. Ward, chairman (president, British Society of Rheology) ; Dr. G. W. Scott Blair, honorary organizing secretary ; Dr. J. G. Oldroyd, honorary treasurer ; Dr. V. G. W. Harrison, honorary editor ; Mr. P. Feltham (honorary secretary, British Society of Rheology, and deputy organizing secretary to the Congress) ; Mr. E. B. Atkinson ; Mr. L. Grunberg ; Dr. E. W. J. Mardles ; Dr. Barbara S. Neumann ; and Mr. N. Wookey. Local arrangements in Oxford are being made by Captain E. W. Geidt. GEOPHYSICAL AND METEOROLOGICAL CHANGES IN THE PERIOD JANUARY–APRIL 1949

By R. P. WALDO LEWIS and D. H. McINTOSH
Meteorological Office, Edinburgh

FROM a study of the daily meteorological ionc spheric and geomagnetic observations made nea London during January–April 1949, Beynon an Brown[1] concluded "that quite marked 27-day recu rence tendencies may sometimes occur throughou the terrestrial atmosphere from the ground to th highest levels, and that such tendencies can b associated, directly or indirectly, with the occurrenc of large sunspot groups and their accompanyin radiations". The truth of this assertion is well estab lished for ionospheric and geomagnetic phenomena but in spite of attempts by many authors, no direc relationship between solar activity and meteorologica events has yet been proved real. The conclusion o Beynon and Brown has, by implication, more tha theoretical interest, since the effect on surface pressur is large enough to merit being taken into account i practical long-range weather forecasting. The perio in question has therefore been examined in som detail, and the results are presented here.

The midday (G.M.T.) values of surface pressure a each of the stations New York, Horta (Azores) Reykjavik, Aldergrove (Northern Ireland), Lerwick Kew, Bordeaux, Lisbon, Copenhagen, Strasbourg an Malta during the four solar rotations (108 days) from January 12 to April 29, 1949, were analysed by mean of a 'successive difference' method to obtain th length of the most marked oscillation period o between 9 and 33 days at each place. At the firs six of the above stations a main period varyin between 25 and 30 days was indicated, while at th remaining five, various other periods were mor marked. This illustrates a feature of meteorologica data which is in contrast to that of most othe branches of geophysics. Whereas, for example, conspicuous ionospheric and geomagnetic events ar generally world-wide in character, even large-scal meteorological events appear to affect only relatively small parts of the earth's surface. The existence o a direct link between solar radiations and regiona meteorological events seems therefore to have an inherent improbability which makes it particularly necessary for any apparent connexion to satisfy stringent statistical tests of reality.

The evidence produced by Beynon and Brown consisted mainly of a striking similarity, at times even in fine detail, of the five-day running mean curves of Kew surface pressure and of deviations from the monthly mean curve of the vertical incidence critical frequency of normal E region (Δf_0E). There was also less striking similarity between the smoothed pressure curves and those for the $F2$ region (Δf_0F2 and magnetic indices K. For reasons to be mentioned later, attention is confined here to the origina unsmoothed data. The amplitude (c) and phase (φ of the Fourier component of length of period 27 day were separately determined for the Kew pressure an Slough Δf_0E series from January 12 to April 2 1949. Allowance was made for eighteen missing Δf_0E midday values by an interpolation process The standard deviation (σ) was determined for each series and the amplitude ratio (a) calculated from the equation :

$$a = \frac{c}{\sigma\sqrt{2}}.$$

s unity for a pure sine curve. The coherence of h series, as measured by the correlation coefficient ween successive terms (r_1), was evaluated and the dified amplitude ratio a_1 was obtained from the mula:

$$a_1^2 = a^2 \cdot \frac{1 + r_1^2 - 2r_1 \cos q\,\alpha}{1 - r_1^2}$$

used by Walker[2]. a_1 represents the amplitude io of the original series with the effects of coherence noved. The values of c, φ, σ, a, r_1, a_1 for each ies are listed in the accompanying table, together th the values of the probability criterion of huster (P_S) and of Fisher (P_F).

	c	φ	σ	a	r_1	a_1	P_S	P_F
ssure	5·6 mb.	224°	8·8 mb.	0 45	0·67	0·23	0·057	0 989
$_0E$	0·08 Mc./sec.	44°	0·10 Mc./sec.	0·68	0 87	0·35	0 001	0 043

From the table, it can be seen that the 27-day ves in the respective series were exactly out of ase, which is in keeping with the inverse relation- p found by Beynon and Brown. For the pressure ies we find that, from a series of 108 random terms, out one period in eighteen, chosen at random from the independent periods of a complete Fourier alysis of the observations, would have an amplitude tio greater than 0·23 (P_S = 0·057), while there is very high probability that at least one of the riods would have such an amplitude ratio $_F$ = 0·989). If, therefore, the 27-day period were e selected at random from the harmonic analysis a group of 108 pressure readings (also selected at ndom), it would be significant at about the 5 per nt level. However, the group of pressure readings nsidered was deliberately chosen because it had the culiarity of a "sequence of four maxima in atmo- heric pressure at approximately 27-day intervals", d we are considering the amplitude-ratio of this -day period which is the greatest in the whole set independent amplitude-ratios occurring in the rmonic analysis of the group of pressure readings. e therefore need to consider the chance that the eatest amplitude-ratio M occurring in the harmonic alysis of 108 random numbers should exceed 0·23. om above we see that 99 times out of 100 M ceeds 0·23. The 27-day period occurring in the lected pressure groups cannot therefore be con- lered physically significant. For the Δf_0E series, s and P_F are respectively about 1 in 1,000 and 1 in , values which suggest that the 27-day period in is series is probably significant, especially since the riod was not chosen because of any feature shown these observations.

The correlation coefficient between the unsmoothed idday pressure values and the corresponding values Δf_0E (90 available pairs) was found to be − 0·22. is common practice in meteorological and geo- ysical papers to imply the significance of a cor- lation coefficient by writing it as $r \pm E$, where

$$E = 0{\cdot}67 \cdot \frac{1 - r^2}{\sqrt{n}}, \qquad (1)$$

being the number of pairs correlated. This practice akes two assumptions which are rarely justified. rst, there is the assumption that the n pairs are dependent, which is never true of successive daily lues in geophysics. It can be shown that the quivalent number of repetitions' in a series of n lues is given by

$$\epsilon(n) = 1 + 2\left(1 - \frac{1}{n}\right)r_1 + 2\left(1 - \frac{2}{n}\right)r_2 + \dots + \frac{2}{n}r_{n-1} \qquad (2)$$

where r_1, r_2, r_3 . . . denote the correlation coefficients between successive terms, terms two apart, terms three apart . . . and so on. In most practical cases r_n becomes negligible after n = 4 or 5. Applying (2), a value of $\epsilon(n)$ = 6 was obtained for the pressure series and of $\epsilon(n)$ = 2 for the Δf_0E series. Such a large difference in the degree of coherence of the respective series is in itself strong evidence against the existence of a significant relation between them. In actual figures, the effective number of independent pairs in the correlated series can be assumed to be between 15 $\left(\text{that is, } \frac{90}{6}\right)$ and 45 $\left(\text{that is, } \frac{90}{2}\right)$. The second assumption made in the application of (1) is that r is distributed normally with standard deviation $\frac{(1 - r^2)}{\sqrt{n}}$. This is true only for $n > 500$: for smaller n, the distribution of r becomes skew[3], and for $n < 50$ the approximation is not valid. The probability that a coefficient r is derived from a population with coefficient ρ is, however, easily obtained from an approximation due to Fisher[4]. This states that $\{(\tanh^{-1} r) - (\tanh^{-1} \rho)\}$ is normally distributed about $\frac{\rho}{2(n-1)}$ with variance $\left\{\frac{1}{n-1} + \frac{4 - \rho^2}{2(n-1)^2}\right\}$. Applying this approximation in the present case, we find a probability of 0·436 that 15 pairs from an uncorrelated normal population will have a correlation coefficient $\geqslant 0{\cdot}22$; for 45 pairs the probability is 0·148. The highest of eight lag correlation coefficients evaluated (four days either side of correspondence) was only − 0·26, when Δf_0E lagged two days behind pressure. It is evident from these figures that the relationship between the two series cannot be considered significant.

The correlation coefficients were also evaluated between the unsmoothed pressure values and those of f_0F2 and K indices. Insignificant coefficients of − 0 06 and + 0·04 respectively were obtained, both from 108 pairs of values.

These results show conclusively that the apparent close relationship between surface pressure and the ionospheric and solar data over this period cannot be accepted as real. The erroneous conclusion drawn from the smoothed data illustrates the danger of attaching too much significance to such data. This is because the taking of running means introduces a high degree of artificial coherence into a series, thereby greatly reducing the number of statistically independent terms. The serial correlations r_1 to r_4 for a series of five-term running means of a random series are: r_1 = 0·8, r_2 = 0·6, r_3 = 0·4, r_4 = 0·2, and are thereafter zero. Only every fifth term may be taken as independent ($\epsilon(n)$ = 5 in equation (2), for large n). It is thus apparent that a large correlation coefficient between two smoothed series may be no more significant than a small one between the corresponding unsmoothed series. In practice, even the unsmoothed series frequently have a high degree of coherence, so that the number of independent pair is in any *case small* compared with the total; th application of five-term running means reduces th number almost to zero.

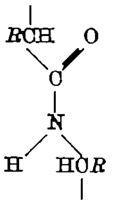
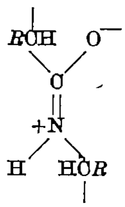
INFRA-RED DICHROISM AND PROTEIN STRUCTURE

CURRENT ideas of the configuration of polypeptide chains in proteins are based largely upon observations of X-ray diffraction patterns[1,2] and infra-red dichroisms[3,4]. While the interpretation of X-ray data is possible by well-established methods, the interpretation of infra-red dichroisms is, at present, subject to certain difficulties. Briefly, these are: (*a*) the lack of information concerning the precise nature of the atomic motions associated with certain absorption bands, and (*b*) the uncertainty in our knowledge of the directions of the transition moments associated with these absorption bands, which depends upon electronic factors as well as the atomic displacements. In the past, it has been generally assumed that the principal absorption bands observed in the infra-red spectra of proteins arise from highly localized bond-stretching or bond-deformation vibrations, so that the associated transition moment directions are along or perpendicular to the bonds according to the type of vibration involved. In view of the weight placed on observations of infra-red dichroisms in the determination of the configurations of protein chains[5], it is important that the inadequacy of these concepts should be pointed out.

An exact mathematical treatment of the normal vibrational modes of the peptide group is impossible in the present state of knowledge, but an approximate treatment may be carried out by analogy with the well-known normal modes of simple molecules. It has been established by X-ray studies of simple peptides[6] that considerable resonance occurs between structures (I) and (II).



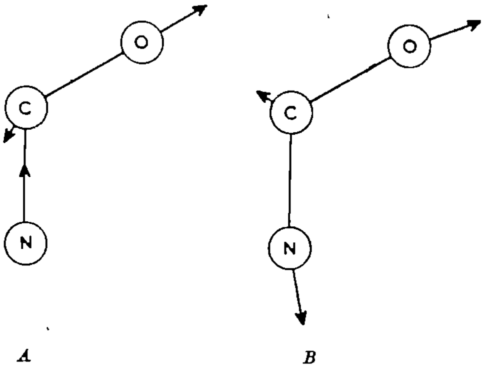
(I)



(II)

As a result, the stretching force constant of the CN bond is greater than that of a normal C—N bond, and that of the C=O bond is correspondingly reduced. The stretching force constants of the CO and CN bonds have been calculated from the observed bond-length, using Gordy's empirical method[7]; the values are $10 \cdot 5 \times 10^5$ and $7 \cdot 8 \times 10^5$ dynes cm.$^{-1}$ respectively, so that considerable mechanical interaction will occur between these bond vibrations. The resulting modes involve motion of all three atoms simultaneously and will, in first approximation, correspond to modes *A* and *B* of a bent triatomic molecule. Mode *A* corresponds to the 'CO'-frequency observed at *c*. 1,650 cm.$^{-1}$ in the spectra of peptides and proteins. The direction of transition moment in this mode will be somewhere intermediate between the directions NC and CO. The extent of the displacement from the CO direction will depend upon the degree of [illegible]echanical interaction.

Approximate calculations indicate that the fre[illegible]ency of mode *B* lies fairly close to that of the NH [illegible]nding vibration. Geometrical considerations show [illegible]t the coupling between these vibrations is very



great, and will result in the appearance of two band the first, corresponding to the out-of-phase mode which there is relatively small motion of the nitrog atom but fairly large deformation of the hydrog atom, is identified with the so-called NH-bendi frequency observed near 1,550 cm.$^{-1}$. This view supported by the spectra of deuterated peptides which this accidental degeneracy is removed[8]. band appears near 1,130 cm.$^{-1}$ in the expect position for an ND-bending vibration, and a furth band appears at *c*. 1,490 cm.$^{-1}$ corresponding mode *B*. The identification of the in-phase cor ponent, confined mainly to motion of the carbon a nitrogen atoms, presents some difficulty; but it m represent the band at *c*. 1,270 cm.$^{-1}$ which is reduc in intensity, as would be expected, upon deuteratio

While the argument outlined is based on an ove simplified treatment of the mechanical problem, su treatments have been applied successfully in the ca of hydrocarbons[9], and should be applicable here. is clear that the transition moment direction asso ated with mode *A* is not along the CO bond, b displaced towards the NC direction. This is purely result of considering the mechanical vibration.

The second factor which influences the transiti moment, and which is probably the more importa one, is the orbital-following associated with the ' vibration. As the CO distance increases, the pr portion of the resonating structures (I) and (I alters in favour of (II). Thus, during the vibration varying negative charge appears on the oxygen, a a corresponding positive charge on the nitrogen ato giving rise to a changing dipole moment in the N direction. There is strong evidence for this effe which results in increased intensity of the carbon absorption in conjugated ketones as well as in amides A similar orbital-following effect is responsible f much of the intensity of the antisymmetrical vale vibration of carbon dioxide at $4 \cdot 2\,\mu$ and accou very satisfactorily for the sign of the bond–bo cross term[11]. A rough calculation based on extinct coefficients indicates that the transition moment the 1,650 cm.$^{-1}$ band in the amide group is inclin at 10–15° to the CO direction as a result of th effect alone.

In order to test the conclusions arrived at, we ha calculated the dichroism to be expected from oriented polypeptide in which the chains have t configuration described by Pauling and Corey f their $3 \cdot 7$ residue helix[12]. The transition mome associated with the 3,300 cm.$^{-1}$ absorption band w assumed to be in the NH direction, that of t 1,650 cm.$^{-1}$ absorption being displaced by 20° fro the CO direction towards NO. The figure of 20° w arrived at by assuming a value of 15° as the displacement due to orbital following and a further 5° due to the mechanical form of the vibration. The effects of imperfect orientation were approximated to by assuming the orientation of 90 per cent of the material to be perfect and the remainder completely random. The values arrived at for the dichroic ratios of the 3,300 and 1,650 cm.$^{-1}$ bands are 15 and 4·1 respectively. These are close to the values observed experimentally by Elliott *et al.* for poly-γ-benzyl-L-glutamate in the folded configuration[13]. We consider, therefore, that these observations are in good agreement with the existence of a 3·7 residue helix, and cannot be maintained as valid objections to it[14].

One of us (R. D. B. F.) wishes to acknowledge the receipt of a Nuffield Foundation Fellowship during the tenure of which this work was carried out.

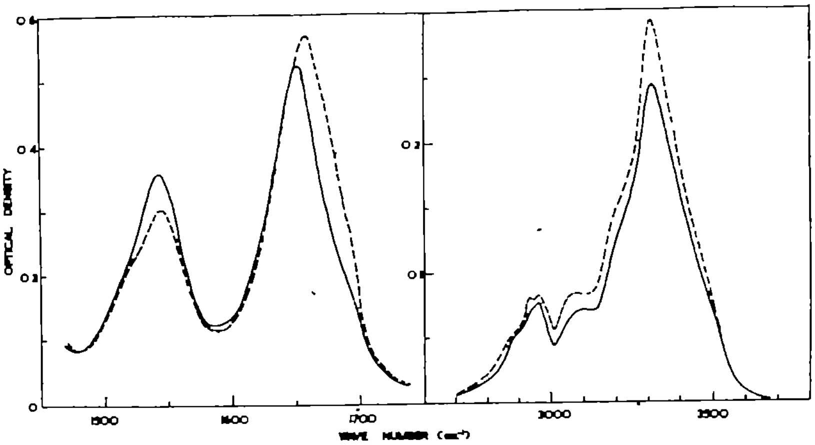
Infra-Red Dichroism of Tobacco Mosaic Virus Nucleoprotein

It has been shown by Elliott and Ambrose[1,2] that the configuration (α- or β-) of a polypeptide chain may be characterized by the dichroism of the infra-red absorption bands associated with the in-plane vibrations of the amide groups. They have also noted that the transformation from the α-configuration to the β-configuration is accompanied by frequency shifts of the so-called CO-stretching and NH-bending absorption bands. From these observations it is possible, therefore, to determine both the configuration and direction of polypeptide chains in an oriented protein structure.

The infra-red dichroism exhibited by oriented tobacco mosaic virus nucleoprotein has been measured in this laboratory using a 0·8 N.A. reflecting microscope in conjunction with a Grubb–Parsons infra-red spectrometer[3]. The microscope attachment was housed in a 'Perspex' box so that the absorption bands of atmospheric water vapour were eliminated. The polarized infra-red radiation was obtained with a selenium film transmission polarizer[4] placed immediately after the exit slit of the spectrometer. Suitable specimens were obtained by smearing a concentrated gel of the nucleoprotein on a silver chloride plate, and the absorption was measured with the electric vector vibrating perpendicular and parallel to the direction of shear, that is, to the axis of the tobacco mosaic virus rod[5]. The results obtained are given in the accompanying record, in which optical density is plotted against wave number for the two directions of the electric vector.



Infra-red dichroism exhibited by oriented tobacco mosaic virus. Absorption with electric vector vibrating parallel to the direction of shear (full curve) and perpendicular to the direction of shear (broken curve)

The dichroisms exhibited by the absorption bands at 3,300, 3,065, 1,657 and 1,544 cm.$^{-1}$ are those to be expected from either β-chains parallel, or α-chains perpendicular, to the direction of shear. The frequencies of the last two bands are, however, those associated with the α-configuration.

It may be inferred, therefore, that the major component of the protein in tobacco mosaic virus exists in the α-configuration, and that the chain axes are preferentially oriented perpendicular to the axis of the rod-like tobacco mosaic virus particle. It is interesting to note that in other fibrous protein structures which have been investigated[6,7] the chain direction has been determined to be parallel to the direction of shearing.

I wish to thank Prof. J. T. Randall for his continued advice and encouragement, Dr. M. H. F. Wilkins, who suggested the problem, for helpful discussions, and Dr. G. Markham for supplying the tobacco mosaic virus. I also wish to acknowledge the receipt of a Nuffield Foundation Fellowship.

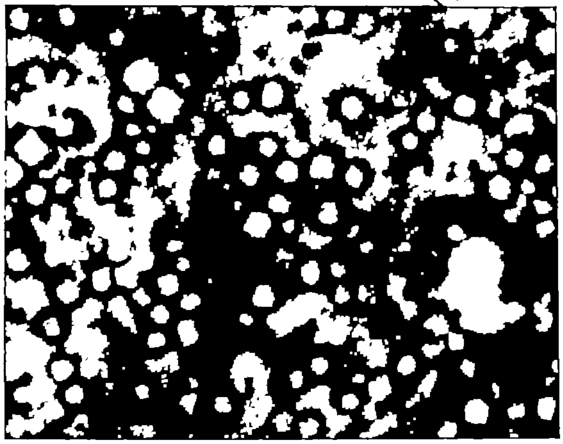
Transmission of Polyhedral Viruses between Different Insect Species

MOST workers with the polyhedral viruses affecting insects have regarded them as strictly species-specific and only transmissible to closely related species with great difficulty. Indeed, previously in such attempted cross-transmissions we have had little success although we have transmitted the polyhedral virus of the common clothes moth, *Tineola bisselliella*, to the case-bearing larva of another species of clothes moth, *T. pellionella*.

Most of the attempts to transmit polyhedral viruses from one insect species to another have been carried out between closely related or similar insects, on the assumption that transmission would be easier in these circumstances. We have, however, disregarded this assumption which, even with plant viruses, is not entirely justified, and have, instead, attempted transmission between the most distantly related lepidopterous larvæ we could find. This gave immediate success, and we have had positive transmissions to the larvæ of the small tortoiseshell butterfly (*Aglais urticæ*) and the peacock butterfly (*Vanessa io*) of no less than seven and five different viruses respectively. These include viruses from the larvæ of the currant moth (*Abraxas grossulariata*), the scarlet tiger (*Panaxia dominula*), the cream spot tiger (*Arctia villica*) and an American species of silk moth (*Telea polyphemus*). Similarly, we have infected the larvæ of the privet hawk moth (*Sphinx ligustri*) with viruses from *P. dominula*, *A. grossulariata* and the silk moth (*T. polyphemus*), and the larvæ of the cinnabar moth (*Callimorpha jacobææ*) with viruses from the larvæ of *P. dominula*, the muslin moth (*Cycnia mendica*), the privet hawk moth and the silk moth previously mentioned. Altogether we have carried out a total of thirty successful cross-transmissions of viruses between larvæ of very different types.

The importance of this discovery lies in the fact that it opens the way for fundamental investigation into the nature of the polyhedra-virus complex, the metabolic basis of polyhedroses and the relationshi between the virus and the type of polyhedral cryst formed. As regards this last point, in the experiment thus briefly outlined, we have found that in stainin properties and morphology the polyhedra whic develop in the new host are similar to, but not alway identical with, those developing in the original hos In the accompanying illustration is shown a phot graph of the polyhedral bodies produced in larv of the peacock butterfly by a virus of the scarle tiger moth. Note that the rectangular shape cha acteristic of scarlet tiger polyhedra is still preserve We do not think, however, that it is permissible t make a definite statement attributing the characte istics of the polyhedral crystal to either virus or hos For example, much seems to depend upon the age the larva at the time of infection, and this in tur seems to be closely connected with yolk metabolis



Polyhedra from a larva of the peacock butterfly produced by a virus from a larva of the scarlet tiger moth ; note the rectangular shape of the polyhedra

One of us (N. X.) has carried out independen experiments on this question, investigating prediction made on the lines of a theory on the development insects and the metabolic basis of polyhedrose Further experimental study of this theory is in pro gress, and the theory and observations will b published elsewhere.

In conclusion, we would state that these experi ments on the cross-transmission of viruses do no invalidate the idea that latent viruses exist i lepidopterous larvæ as previously suggested[1], thoug they do throw a new light on the situation.

Variation in *Vi*-Phage II of *Salmonella typh*

THE recent description of phenotypic variation i bacteriophages by Luria[1] and Bertani[2] has prompte us to publish the results of experiments carried ou in 1947 which show analogous features.

The object of the work was primarily to investigat the possibility of tracing a specific *Vi*-phage type o *Salmonella typhi* in which 'degraded' variants ha arisen (see Craigie and Felix[3]). It was hoped als to gain more information about the mechanism o 'degradation' of cultures and the processes concerned in the adaptation of *Vi*-phage II of Craigie and Yen[4] to the specific *Vi*-types of *Salm. typhi*. Degradation in a specific *Vi*-type can take all forms from th appearance of minor cross-reactions with heterologou phages, typical of partly degraded strains, to th full susceptibility to all adapted phages whic characterizes Type *A*.

Our experiments showed that it is not possible by the adaptation of *Vi*-phage II to a degraded variant to prepare phages bearing the specificity of the typ from which the degraded variant has sprung. Thi was reported at the fifth International Congress fo Microbiology in 1950[5].

Valuable information was obtained on the mechanism of adaptation of *Vi*-phage II to the various *Vi*-types of *Salm. typhi*, and it is this aspect of the work which is summarized here. A full account will be given by us later.

In their original description of the *Vi*-typing phages, Craigie and Yen[4], and Craigie[6] suggested that the acquisition of type specificity by the adapted typing preparations was due to the selection by the different strains of *Salm. typhi* of host-range mutants already present in any phage preparation used for adaptation. This concept was used as the working hypothesis on which they selected their different *Vi*-type strains of *Salm. typhi*.

Our work was carried out with degraded strains isolated from specific *Vi*-types of the typhoid bacillus. The strains were further subdivided by plating into single-colony lines, some of which reacted as Type *A*, while others gave the incomplete cross-reactions characteristic of 'degradation'. Table 1 shows the origin of the eight strains employed, with a description of their *Vi*-phage reactions.

Table 1

Original *Vi*-phage type of strain	No. of strains	*Vi*-phage reaction of selected 'degraded' substrains
D 5	2	Type *A*
N	3	Degraded
O	2	Type *A*
T	1	Type *A*

The following ten adapted *Vi*-typing phages were propagated on these strains: phages *C*, *D* 4, *D* 5, *D* 6, *E* 1, *F* 1, *L* 1, *N*, *O* and *T*. All phages were grown from selected single plaques.

Results. The phages grown on organisms which gave the full Type *A* reaction fell into two groups, as shown in Table 2.

Table 2

Phages changed to phage *A* on propagation	Phages propagated unchanged
C	*D* 5
E 1	*D* 6
F 1	*O*
L 1	*N*
T	

Phage *D* 4 was propagated as phage *D* 1 on Type *A*; this will be discussed later.

The change from the various adapted phages to phage *A* occurred uniformly in all the many plaques cut. The phage *A* so produced was indistinguishable from the ancestral phage *A* and again contained variant particles able to attack other types; no indication could be found that the phage had propagated as the former type, and it was concluded that the change from the former type (that is, *C*, *E* 1, *F* 1, etc.) to phage *A* had occurred in a single step commencing with the particle initiating each plaque which had been cut. This 100 per cent reversion of adapted phages to the original phage *A* suggested that, whatever was responsible for the production of adapted phages with a newly acquired host-range, the process did not involve the selection of stable host-range mutants but of particles capable of undergoing a change which, for convenience, may be described as phenotypic variation.

It is not clear from these experiments whether the initiation of plaques during the adaptation of phage *A* to heterologous types of *Salm. typhi* results from the selection either of particles possessing this susceptibility to modification, or of organisms metabolically different from the general population that are able to initiate the change in any particle. The fact that the number of plaques produced by phage *A* on a heterologous type is proportional to the concentration of phage suggests that the former hypothesis is more likely to be correct.

In contrast, the four phages which were propagated unchanged (phages *D* 5, *D* 6, *O* and *N*) behaved as stable host-range mutants; we were unable to change them to phage *A* by propagation on organisms giving the full Type *A* reaction. That a phage behaving as a host-range mutant may nevertheless show phenotypic variation is evident from the change of phage *D* 4 to phage *D* 1 on Type *A* strains. Phage *D* 4 was first produced by adapting phage *A* to Type *D* 1[4] and then adapting the resulting phage *D* 1 to Type *D* 4[7]. In this case, phage *D* 1 could be regarded as a selected host-range mutant of phage *A* and phage *D* 4 as a phenotypic variation of phage *D* 1.

It may be added that the terms 'phenotypic variation' and 'host-range mutant' are used in order to interpret the phenomena observed in a way comparable to that in current use by bacteriophage workers. It is possible that the whole process of 'adaptation' of *Vi*-phage II may be a phenotypic change, and that the 100 per cent reversion of phages *D* 5, *D* 6, *O* and *N* to phage *A* has not yet been observed because the correct organism has not been employed which can act as a 'trigger' to cause the change. More work is needed on this group of phages.

Phages grown on organisms giving the degraded reaction (see Table 1) gave results which were more difficult to interpret than those described above. In the first place, these strains were much less sensitive to the phages used than were Type *A* strains, and it was often impossible to find plaques which could be propagated. Secondly, plaques when found were extremely small and difficult to cut. Phage *T* propagated on a degraded strain descended from Type *N* yielded a phage which was able to attack Types *A*, *N* and *T* with equal ease. It would appear that a strain cannot change a specific phage to phage *A* unless it possesses the full phage sensitivity characteristic of Type *A*, and that a strain which is a partly degraded variant of one of the specific types is capable of modifying *Vi*-phage II so as to yield a phage of indeterminate specificity. Only a few phages were grown by propagating phage *T* on the degraded Type *N* substrains because of the insensitivity of the latter to phage *T*, but all these phage preparations conformed to the pattern described above. The change involved could, therefore, be provisionally regarded as fitting into the phenotypically altered group in which phage *T* has been placed.

It is apparent that the original policy[1] of using phage *A* as the parent phage for adaptation to new typhoid *Vi*-types in the preparation of the routine typing phages was a sound one, because phage *A* is highly specific for Type *A* of the organism and a new phage descended from it acquires the additional ability to attack only the new type used for adaptation. In contrast, phages descended from a host-range mutant, such as phage *D* 6, may retain in full the ability to attack Type *D* 6 and will then lyse Type *A*, Type *D* 6 and the type to which they have been newly adapted.

It is interesting to note that the phenotypic variation which can be induced in *Vi*-phage II is conditioned, in some cases at least, by the alterations produced in the typhoid bacillus by bacteriophages carried by some *Vi*-phage types of the organism[8–11]. The resistance of such types to phage *A* is clearly an exclusion phenomenon, and it seems remarkable that the presence in the bacterial cell of one kind of phage should be responsible for inducing a specific phenotypic variation in another, apparently unrelated, bacteriophage.

Adrenal Cortical Hormones in Human Placenta

11-Dehydro-17-hydroxycorticosterone (cortisone) and a number of other adrenal cortical hormones and their metabolites have been found in human placentas. The ethyl acetate extract of a finely minced placenta, freed from blood so far as possible, was evaporated to small volume, washed with 0·2 *M* sodium carbonate, 0·2 *N* hydrochloric acid and 0·1 *M* sodium acetate and evaporated to dryness. The residue was taken up in petroleum ether and extracted with 70 per cent aqueous ethanol. The united lower layers were evaporated to dryness, and the residue was taken up in benzene which was extracted ten times with equal volumes of water. The united aqueous layers were extracted with chloroform, and the extract dried and evaporated to dryness. The residue was examined by paper chromatography at 37° using a benzene–50 per cent methanol system[1]. Several α,β-unsaturated ketonic substances were present. That present in largest amount reduced triphenyl tetrazolium chloride, had the same R_F value as cortisone and gave a blue colour with iodine. Elution with 90 per cent ethanol was followed by evaporation to dryness and acetylation with acetic anhydride in pyridine. The resulting acetate was examined by paper chromatography at 37° using a benzene–petroleum ether (1 : 1) : 80 per cent methanol system, and was found to have the same R_F value as cortisone acetate. Rough estimation of the fluorescence in ultra-violet light after treatment with methanolic caustic soda indicated a yield of approximately 100 μgm. cortisone per placenta. Traces of 17-hydroxycorticosterone are also present, and at least three other α,β-unsaturated 3-ketosteroids which are at present unidentified.

Changes in the Flow Birefringence of Myosin as a Result of Muscular Atrophy

Many of the changes in atrophic muscle are perhaps consequences of diminution of tension. Th special importance of myosin has prompted severa workers to look for changes in its physicochemica properties as a result of atrophy. Apart from decrease in the concentration of myosin[1], an changes in its anabolism[2], there has been noticed onl a greater fragility of myosin threads[1]. While diminution of birefringence of whole muscle has bee observed[3], that of pure myosin has not as yet bee studied.

We have undertaken a systematic study of dilut solutions of myosin, prepared according to the tech nique of Mommaerts[4], from normal and atrophi rabbit gastrocnemius. The muscles were sample ten to thirty days after unilateral section of th sciatic nerve. The intact muscle was always take as control.

Using a technique developed by one of us[5,6], w have measured the angle of extinction from whic the length of the most frequent particles present i the solution was determined. The precision of th method is about 1 per cent. From the measuremen of intensity of birefringence we have determined th mean afferent anisotropy of the particles[6]. Seventee experiments have been carried out with thirtee different rabbits. All determinations were made i 0·5 *M* potassium chloride for myosin concentration ranging between 0·006 and 0 028 per cent and a *p*H 6·2–7 9. Concentrations have been determine by Kjeldahl's method to ± 2 per cent. The result are summarized in the accompanying table.

C per cent	*p*H	Time in days	Atrophic		Normal	
			l_f	$\bar{A} \times 10^3$	l_f	$\bar{A} \times 10^3$
0·012	6 7	16	2750	2 8	3050	2 4
0·006	6 2	,,	2600	6 3	2700	5·4
,,	7 1	,,	2800	6 2	2900	5 2
,,	7 2	,,	2650	6·5	2800	5 3
0 016	6·4	30	2800	2·4	2850	2·1
,,	7	,,	2750	2 6	2850	2 3
,,	7 2	,,	2700	2 6	2950	2 3
,,	7 7	,,	2750	2 6	2800	2·4
0 0076	6 5	14	2750	5 4	2800	5·3
,,	7 9	,,	2700	5 8	2750	5·2
0 015	6 5	,,	2700	2 3	2750	2
,,	7 6	,,	2800	2 1	2850	2
0 019	6·5	,,	2800	2 1	2850	2
,,	7 2	,,	2700	2 3	2800	2 1
0 028	6 6	,,	2800	1·3	2850	1·1
,,	7 7	,,	2800	1 3	3000	1 1
0·025	6 0	30	2700		3000	1 3

For all solutions, the length of the most frequent particles, l_f, is smaller for myosin extracted from atrophic muscle than for myosin from normal muscle On the other hand, the mean anisotropy of particles $\bar{A}$, is higher for atrophic than for normal muscl myosin. The duration of atrophy (ten to thirty day has no detectable influence upon the results. Th mean value of length of most frequent particles i 2850 A. for normal myosin at the concentration studied.

The mean value of the ratio l_f(atrophic)/l_f(normal) is 0·94 ± 0 006; while the mean value of the rat $\bar{A}$(atrophic)/$\bar{A}$(normal) is 1·1 ± 0·01. Consideri the precision of the technique, these values ar highly significant.

The afferent anisotropy of the particles varie markedly with protein concentration[7], so that $\bar{A}$ i approximately inversely proportional to myosin con centration. It is therefore necessary to determine th sotropy ratio at the same concentration. A iation of l_f with concentration can also observed[7]; but for a large range of contrations these variations are very small, and nor errors in concentration would have no ring upon the results regarding length of ticle.

urther work is required to explain these rets. However, it may be worth while to consider following provisional explanations :

1) Contamination of the preparations, especially myosin from atrophic muscle, with actin, is unly, since addition of adenosine triphosphate does decrease birefringence, as would be the case if ne actin were present.

2) A modification of extractability of different osins, as Dubuisson[8] observed after muscular contion, is possible. Investigation of the electroretic properties of myosin prepared from normal l atrophic muscle is under way in an attempt to cidate this problem.

3) Finally, it may be that myosin of atrophic scle is actually modified in some manner. If this ved to be true, it would represent, as Pauling described for hæmoglobin, a "molecular disease".

his work was assisted by grants from the Centre tional de la Recherche Scientifique, the Institut tional d'Hygiène and the Caisse Nationale de urité Sociale.

ectrical Resistance and Structure of the Hen's Egg

HE yolk and white of the hen's egg show wide ferences in osmotic pressure, pH and ionic comsition, which are maintained for a long period of e on storage. This has frequently been supposed result from a property of the vitelline membrane ich separates the two phases, although J. Needham, o has recently reviewed this subject[1], has conded that there must be the co-operation of some sical property of the yolk and white.

s this property can only be a barrier to diffusion, l might be reflected in a low electrical conductivity, s has been measured for the various structures the intact egg. The electrodes were of platinum re coated with varnish except for 3 mm. at the , which was flattened to increase its conducting ea, and blackened.

	White (Δ = −0·44° C.)	Yolk (Δ = −0·56° C.)	
		Broken-up	Intact
Conductivity Median (mho/cm. × 10^{-4}, 18° C.)	8·25	2·84	0·070
Range	6·7–9·4	2·5–3·4	< 0·05–0·11
Diffusional resistance	1·3	4·85	200

One electrode was pushed up from below through the intact yolk until close below the upper surface of the vitelline membrane, and the other brought into proximity in the white lay upon it. When the membrane was ruptured between them, there was no marked change in resistance. This indicated that it was not an important barrier and would have to be isolated in order to estimate its contribution. Accordingly, the membrane was carefully washed free of yolk with homogenized white, and introduced between the closely spaced electrodes of a Kohlrausch cell under some more of the same liquid. On withdrawing the membrane, a just measurable decrease of resistance was produced—one that could have been compensated for by about a 30-μ increase in the electrode spacing.

Two wire electrodes mounted side by side, 4 mm. apart, were used to measure the conductivity of the white and yolk. Summarized in the table are the results from 24 eggs from one day to four months old ; however, no marked trends with age were found. Shown also is the ratio between the median conductivity of each phase and that of an isotonic sodium chloride solution, which is a rough indication of the resistance to ionic diffusion. A stock 1 per cent sodium chloride solution served throughout as a standard of conductivity.

The conductivity of the white was not significantly different *in situ* or after separation and homogenization.

The yolk, however, showed a much lower conductivity when the electrodes were introduced into it through a small cut in the membrane than when it had been broken up by separating it in a syringe. The measured value often differed appreciably from point to point in the intact yolk, probably as a result of damage caused by the electrodes, and, though minimum values are quoted in the table, they are possibly still too high. Making allowance for this variability, the conductivity seemed to be uniform and isotropic throughout the outer ½–1 cm. of yolk, but generally rose tenfold towards its centre.

To explain this high resistance to diffusion, there must be some internal structure in the yolk—a continuous solid phase, which can be easily broken down mechanically to yield a continuous aqueous phase. On the basis of these results, no other factor would appear to be responsible for the delay in equilibration in the intact egg.

This work was carried out while on leave from the Medical Research Council, with a scholarship from the Italian Government. I wish to thank Prof. S. Visco for the hospitality of his Institute and for introducing me to the problem.

Division of the Flattened Egg

It has long been known that when a fertilized egg is flattened between two plates it may cease to divide. Zeuthen[1] has shown recently that although cell division is inhibited, nuclear division may continue, so that many nuclei may be present in a single flattened cell. I obtained essentially similar results during the summer of 1951, at Roscoff. It was found that, if the egg was not too greatly compressed, it would eventually divide and, once division set in, cleavage of the cytoplasm would continue until the normal ratio of one nucleus to one cell was re-established.

When the degree of flattening is too great to permit cleavage, eventually bodies of granular cytoplasm may segregate around the individual nuclei, separated from one another by gelled cytoplasm. The volumes of these segregates of granular cytoplasm are often similar to the volumes of the cells which would have existed at that stage if division had been possible. For example, at the 16-nuclei stage there are four segregates which are much smaller than any of the others, corresponding to the four micromeres of the 16-cell stage.

It was also observed that if a number of eggs were flattened by the weight of a small glass plate, the degree of flattening was not constant. Between divisions the flattening was maximal. Just before cell division the degree of flattening diminished sharply, so that the upper glass plate was raised. Then after division the degree of flattening increased. This cycle of events was repeated at each division.

The simplest explanation of the change in ease of deformation is that immediately before division there is an increase in the tension at the cell surface, and that in the plane which was occupied by the metaphase chromosomes this tension reaches a higher value than elsewhere, so that cleavage ensues in this plane. When cleavage is complete the tension falls off to its original value, only to rise again before the next cleavage.

Fish Feeding on *Simulium* Larvæ

During investigations on the food of migrating fish in the Tanganyika region, a species of fish (*Varicorhinus tanganicæ* Boulenger) was found to feed on algæ, diatoms and insect larvæ covering stones and bottom in streams. *Simulium* larvæ proved to be the principal item of the food of *Varicorhinus*.

In 120 fish, 51 per cent were found to contain *Simulium* larvæ or pupæ, 48 per cent Ephemeroptera nymphs, 47 per cent Chironomids, 30 per cent other insects and 40 per cent plant material. In some of the stomachs the number of *Simulium* larvæ was very high, in some cases more than 50 (once 57).

The structure of the mouth in the genus *Varicorhinus*, with sharp edges in place of true lips, seems to be well adapted to scraping stones and weeds. *Varicorhinus* spends a part of its life in Lake Tanganyika, where the mineral content of the water is high, and another part in the affluent streams where the mineral content is low. It is able ascend very rapid streams and withstand strc currents. The temperature of its home waters v found to vary between 17° and 27° C. and th electric conductivity between 49·7 and 566·2 × 1 mhos. The bottom of its home waters is often stor but in the Lake it lives among weeds as w *Varicorhinus tanganicæ* seems thus to be a ve adaptable fish to varied external conditions.

The interest of the observations on food is th *Simulium* larvæ are sometimes very common in t rapid streams of East and Central Africa, and m give rise to swarms of very disagreeable flies, so species of which carry diseases of man and catt *Varicorhinus tanganicæ*, or perhaps other spec of the genus from rivers, could probably be int duced in regions where blackflies constitute a pe as in the Nile near the Ripon Falls in Uganda.

Discovery of *Tetragonurus* Risso, 1810, in South African Waters

The rare oceanic form *Tetragonurus cuvieri* Ris 1810, has been known with some certainty since t sixteenth century from an account by Rondelet. has at intervals been reported, mainly as sing specimens, from the following localities: Medit ranean (sixteenth century onwards); Madeira (1839 Australia (1882 onwards); North Atlantic (1895 Hawaii (1928); California (1936 onwards); Jap (1939); New Zealand (1948). This fish has therefo been found over a wide range of temperate se but not hitherto in the Indian Ocean or in t adjacent Western Pacific.

A specimen of *Tetragonurus* has recently be found on the south coast of Natal, at about 31° This is noteworthy as the first record from the Indi Ocean. In addition, its characters and the locali have an important bearing on the question of wheth all the specimens so far discovered are all one rath polymorphous species, or whether more than o exists.

A detailed description and figures of this fish w be published later.

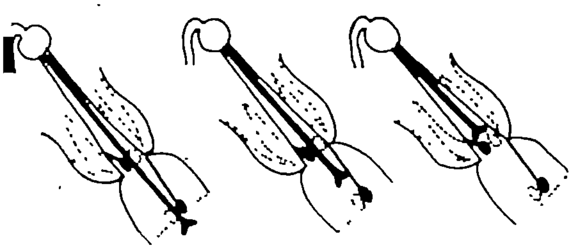
Trimorphism and Self-incompatibility in *Narcissus*

In 1887[1] and 1888[2] the Portuguese botani Henriques described trimorphic heterostyly in tv forms of *Narcissus* which he called *N. triandrus* and *N. reflexus* Brot., both belonging to *N. triandr* *sensu lato*. Though detailed studies have been ma of trimorphic heterostyly in *Lythrum*[3] and *Oxal* the only subsequent investigation of this phenomen in *Narcissus* seems to be a recent one by Fernande who published the frequencies of the three styl lengths in natural populations and speculated on t



Long-style Mid-style Short-style

The three flower forms of *Narcissus triandrus*

enetic determination. The frequencies were 1 long L) : 4 mid (*M*) : 1 short (*S*) in *N. triandrus* and : 2 : 1 in *N. reflexus*.

In 1950, Dr. Fernandes kindly sent me from ortugal collections from two populations of *N. iandrus* var. *concolor*. Fifteen plants have flowered us spring. From this small amount of material it is ready possible to draw several conclusions.

1. Like most other *Narcissus* species, homomorphic nd heteromorphic, *N. triandrus* is self-incompatible, etting no seed or a few shrivelled seeds on selfing.

2. All plants can be classed as long-styled, mid-tyled or short-styled.

3. The anthers are at the same two levels in all ne individuals so far observed. This contrasts with *ythrum* and *Oxalis* in which there are three levels 1 the flower in each form, occupied by stigma or nthers, so that as the stigma alters in height so must he anthers move also.

In *N. triandrus* the three stigma levels are : above he upper tier of anthers ; between the two tiers ; nd below the lower tier (see accompanying figure).

4. Though self-pollination is consistently sterile, ross-pollination between plants of the same style-ength is just as fertile as that between plants with ifferent style lengths (see table).

L selfed	0	*L* × *L*	0	*L* × *M*	74
	0		45		54
	0		48		
M selfed	0	*M* × *M*	71	*L* × *S*	21
					0
S selfed	0	*S* × *S*	9	*M* × *S*	72
	2 (shrunken)		27		
				S × *M*	38
Total ripe seeds from 6 capsules	0		200		259

Seed set per capsule in *N. triandrus* pollinations. Long, mid and short-styled forms are represented by *L*, *M* and *S*

Thus the three flower forms do *not* correspond to hree inter-fertile intra-sterile mating groups as *Lythrum* and *Oxalis*. There is some indication f cross-incompatibility, but since each cross is epresented by a single capsule this would have to e confirmed.

It is probable, then, that the self-incompatibility *N. triandrus* and also of the rest of the genus is ue to a multipolar incompatibility system, the poly-orphism for style-length being an independent henomenon of problematical value to the species.

It may be doubted whether this polymorphism an truly be regarded as trimorphism, for in the small umber of plants examined the style-length within ny one of the three groups has been very variable. t is possible, therefore, that we are dealing with con-inuous variation. If this were so, it would be ex-ected that the mean length (mid-style) would also e the mode (that is, the most frequent), as Fernandes found in natural populations. The idea of 'trimorphism' probably arose from the fact that with the two distinct anther heights as markers any variation in style length falls naturally into three classes : below the lower tier, between the two tiers and above the upper tier.

Permeability of Isolated Rat Heart Sarcosomes

THE study of the permeability of mitochondria, to which the sarcosomes of cardiac muscle are closely related, has depended on indirect, mostly biochemical, methods[1,2]. One of the difficulties in any other approach has been the relatively great (and obviously abnormal) permeability of isolated mitochondria or sarcosomes to most ions at room temperature, which results in swelling and other morphological changes. With the discovery that Ca^{++} ions are intimately related to this abnormal permeability of sarcosomes and that the calcium-chelating agent versene, by removing calcium from the granules, greatly increases their stability at room temperature[3], the problem of sarcosome permeability has become more accessible to attack by other methods.

Two methods, previously used in studies of red cell permeability, suggested themselves for such a study : (i) determination of the rate of onset of the morphological changes in different suspending media (analogous to the hæmolysis method in red cells),

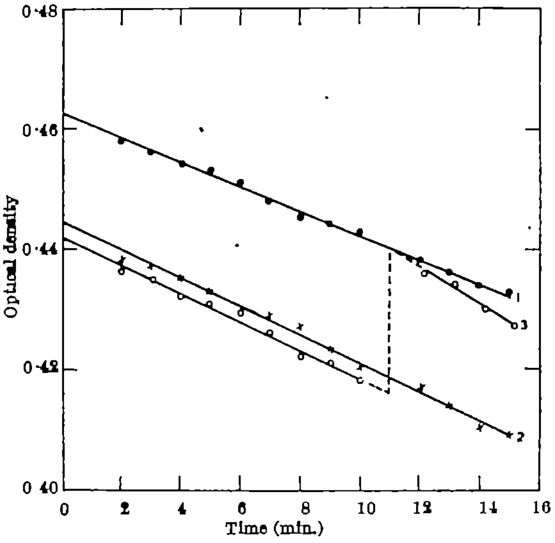

Fig. 1. Measurement of swelling in hypotonic medium and of rate of permeability of solute : curve 1, sarcosome suspension diluted with 0·165 *M* potassium chloride in Beckman cell at zero time ; curve 2, the same, except that 0 125 *M* potassium chloride was used : curve 3, as curve 2, except that at 11 min. sufficient potassium chloride was added to bring final concentration to 0·165 *M*

and (ii) study of the rate of change of the light-scattering properties of sarcosome suspensions. Some observations made with the latter method are here described. The method consists of studying the rate of change in optical density of sarcosome suspensions in 1-cm. cells in the Beckman spectrophotometer at 520 mμ.

When a suspension of sarcosomes in isotonic buffered saline containing versene (0·115 *M* potassium chloride, 0·02 *M* phosphate, 0·01 *M* versene, *p*H 7·4) is diluted in a Beckman cell with isotonic saline (0·165 *M*), the optical density slowly decreases with time, as shown in curve 1 of Fig. 1. The optical density at zero time is obtained by the extrapolation shown. If the sarcosomes are diluted with hypotonic saline (0·125 *M*), there is an immediate rapid fall of the optical density (see curve 2), complete before the first reading is taken, followed by the same slow decline shown in curve 1. By extrapolating curve 2 to zero time, an optical density corresponding to 0·125 *M* potassium chloride is obtained. In this way the curves relating optical density to the concentration of potassium chloride, shown in Fig. 2, were obtained.

Both the rapid decrease of optical density and the slow decline are due to swelling of the sarcosomes, which results in less light scatter, presumably because of a decrease of refractive index of the sarcosome on swelling. The rapid change is due to movement of water in response to the hypotonic conditions; the slow-decrease is due to permeability to solute and affords a quantitative measure of the permeability. In this communication, the permeability is expressed as the reciprocal of the time (in minutes) required for a change of 5 per cent in the initial optical density (0·3–0·5) of the suspension.

After short time exposures to hypotonic conditions, the original density is regained when isotonicity is restored, although in most experiments there was evidence that the hypotonic swelling had caused an increased permeability to the solute. A typical experiment is shown in curve 3 of Fig. 1.

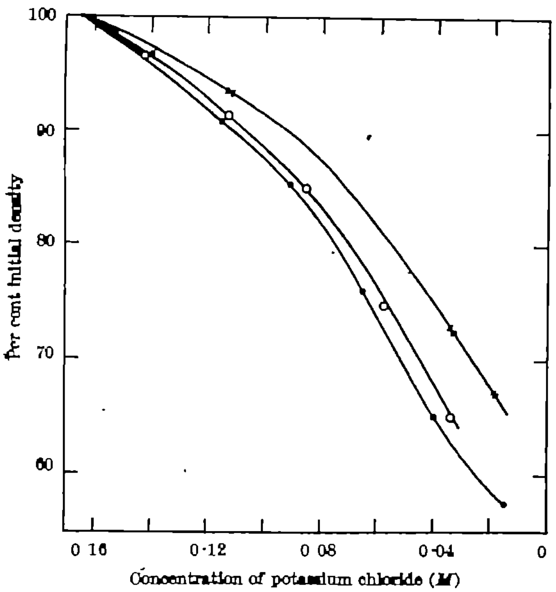

Fig. 2. Relation between initial optical density and tonicity of suspending medium (potassium chloride). The optical density is expressed as a percentage of that found in 0 165 *M* potassium chloride. The curves are for three different sarcosome preparations

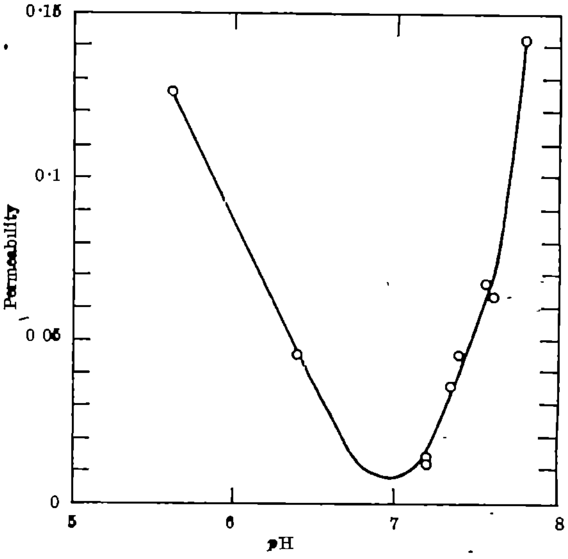

Fig. 3. Effect of *p*H on permeability to potassium chloride

Some typical permeabilities, determined on the same sample of sarcosomes, are: potassium chloride 0·02; sodium chloride, 0·013; glucose, 0·024; and sucrose, 0·006. The initial density in isotonic solutions of these four solutes was the same. Glycero and ethylene glycol exerted no appreciable osmotic effect (permeability greater than 10). The permeability to potassium succinate, fumarate and malate is of the same order as the permeability to potassium chloride.

The permeability to potassium chloride has varied considerably in different experiments (range 0·1–0·01) Slight differences of *p*H may have contributed to this variability, since *p*H has a very pronounced effect on permeability, as shown in Fig. 3. Another source of variability may be the level of endogenous adenosinetriphosphate in the sarcosomes. Added adenosinetriphosphate (0·0025 *M*), which greatly diminishes the permeability to potassium chloride o sarcosomes untreated with versene, also decreases the permeability of those treated with versene. This effect of adenosinetriphosphate is not only, or even mainly, due to a change in the swelling properties o the granules, since hypotonic swelling is not greatly affected by its addition.

The curves for swelling in Sørensen phosphate buffer are different from those of other substances in that there is a rapid initial swelling, complete before readings can be made, and thus resembling the swelling in hypotonic media, followed by a slower penetration ultimately resulting in the same degree of swelling as in distilled water. This suggests that only one molecular species of the phosphate buff acts osmotically, while the other rapidly penetrates the sarcosomes. The degree of the initial swelling suggests that it is the disodium hydrogen phosphate component which is rapidly penetrating. In agreement with this explanation, it was found that, when phosphate buffer calculated to be isotonic in respect of potassium dihydrogen phosphate (0·825 *M* Sørensen buffer, *p*H 7·4) was used as suspending medium, the initial density was the same as that found in isotonic potassium chloride.

This work will be continued and will be published in full elsewhere. It was done during tenure of a intenance grant from the Agricultural Research uncil, while on leave from the Department of stology and Embryology, University of Sydney.

Inhibition of Gastric Secretion of Hydrochloric Acid *in vivo* by Carbonic Anhydrase Inhibition

THIS preliminary communication on the inhibition acid secretion *in vivo* in dogs by one of a new group potent carbonic anhydrase inhibitors is prompted the recent report of Davies and Edelman[1], which s appeared since our work was completed. These orkers have shown that several other known carbonic hydrase inhibitors, which include prontosil, *p*-luenesulphonamide, *p*-sulphonamidobenzoate and iophene-2-sulphonamide, can suppress the *in vitro* id secretion of the isolated frog and toad gastric ucosa, although sulphanilamide was without fect.

We employed the hetero-cyclic sulphonamide -acetylamino-1,3,4-thiadiazole-5-sulphonamide, hich is 440 times as potent as sulphanilamide for e 100 per cent inhibition of carbonic anhydrase *vitro*[2]. The single intravenous injection of this aterial in doses of 20–60 mgm./kilo inhibited 79– per cent (mean, 89 per cent) of the output of drochloric acid from Heidenhain pouches in three anaesthetized dogs, stimulated by the subcutaneous jection of 0·025 mgm. of histamine base every min. This inhibition, which occurred after a tent period of 20–80 min., persisted for at least -6 hr., and the secretory function appeared to be mpletely recovered in 24 hr.

It has been predicted by previous workers that any gree of carbonic anhydrase inhibition sufficient interrupt the process of acid secretion by the rietal cell must lead to the speedy death of the mal by virtue of interference with carbon dioxide nsport by the blood, yet no toxic reactions were erved in this dose-range.

When the dosage was extended to 120 mgm./kilo, o of these dogs expired in respiratory arrest, while e two other pouch dogs as well as two unoperated gs tolerated this dose well. There was no increase the degree of acid inhibition at this dose-level.

The details of these experiments will be published ewhere.

Nature of Reticulin

THE main obstacle to the characterization of reticulin has always been its close association with collagen. As a preliminary to an attempt to establish the nature of reticulin fibres, a histological survey of all likely tissues was carried out, and it was found that the mid-cortical connective tissues of the kidneys of children free from renal disease consist almost entirely of reticulin. The only collagen present in this situation occurs in the immediate neighbourhood of the larger blood vessels.

Reticulin was identified histologically as fine branching fibres which appear black when appropriately treated with any of the modifications of the Maresch–Bielschowsky silver-impregnation technique; take up the acid aniline dye in the Mallory connective tissue stain; show little or no fuchsinophilia in sections stained with van Gieson's picro-fuchsin; and appear red when subjected to the McManus periodic acid–Schiff's reagent procedure.

Collagen was identified in histological preparations as bundles of non-branching fibres which assume a yellow-brown colour in untoned Maresch–Bielschowsky type preparations; take up the acid aniline dye of Mallory's connective tissue stain; show well-marked fuchsinophilia when stained with van Gieson's picro-fuchsin; and give a negative reaction to the periodic acid–Schiff's reagent test.

By a process of careful dissection, followed by maceration of frozen sections of unfixed tissue in decinormal sodium hydroxide, reticulin was isolated and prepared for electron microscopy and X-ray diffraction study. Histological control was exercised throughout to ensure that the specimens consisted only of histologically acceptable reticulin and contained no collagen.

Other samples of reticulin, known to be contaminated with collagen to a greater or lesser extent, were prepared in the same way from human liver, lung, adrenal, spleen, lymph-nodes and myocardium for purposes of comparison. Reticulin has also been suggested as one of the components of the organic matter of teeth, and the present investigations indicate that it is probably present in dentine.

Reticulin from all sources produced essentially similar appearances. In electron micrographs of unshadowed specimens it appeared as very thin laminated membranes made up of a network of minute randomly arranged fibrils embedded in an apparently structureless membrane, the relative proportions of fibre and matrix varying in different specimens, even in material obtained from the same source.

In specimens shadowed with uranium the fibrils show a striated structure, the period of the striations being of the order of 650 A. Occasional bundles of fibrils were seen which were sufficiently large to be visible in an optical microscope. These bundles were only seen in material from specimens known to contain collagen. No bundles of fibrils which would be visible with an optical microscope were found in the specimens from renal cortex. In specimens in which aggregation of the fibrils into bundles had occurred, the fibril diameters were usually 400–500 A. In other specimens fibrils as small as 100 A. in width were sometimes encountered. The supporting membranes appeared to vary in thickness. Areas photographed were usually in the range 50–150 A. The illustrations (Figs. 1 and 2) are of an adrenal specimen (× 30,000). Electron micrographs of specimens which had been boiled in water and then shadowed showed that

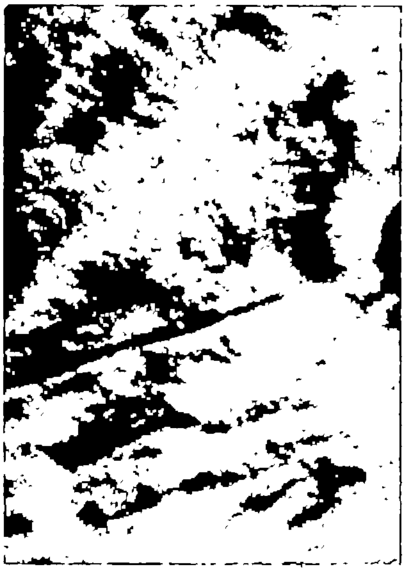

Fig. 1

boiling effects solution of the fibrils but not the underlying matrix. The fibrils differ from ordinary collagen in that no gel results on cooling concentrated solutions.

Preliminary chemical investigations of the apparently structureless matrix in which the fibrils lie suggest that it is a glucoprotein. It is remarkably stable to boiling water; even twenty-four hours boiling does not cause it to dissolve, but merely reduces it to a finely granular precipitate.

X-ray diffraction photographs of specimens which have been boiled to remove the fibrils show a characteristic and as yet unidentified pattern. Samples of dried unboiled reticulin produce photographs which appear to be a mixture of the diffraction patterns of this material and unoriented collagen, with the collagen pattern usually predominating.

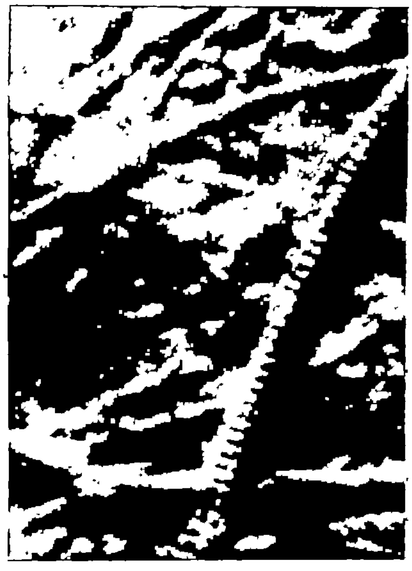

Fig. 2

Preliminary studies thus indicate that reticuli wherever it occurs, has a membranous structure. I consists of minute randomly oriented collagen-typ fibrils embedded in a structureless matrix, which i probably a glucoprotein. In connective tissues ther is a continuous series of structures from this appea ance to the familiar collagen picture, the transitio from reticulin to collagen involving orientation c the fibrils and their aggregation into bundles, an at the same time a decrease in the proportion of th structureless matrix.

Thanks are due to Dr. J. Thewlis and Dr. A. H. T Robb-Smith for encouragement, to the latter fc permission to use post-mortem material, and to th Director of the Atomic Energy Research Establisl ment for permission to publish this communicatioı

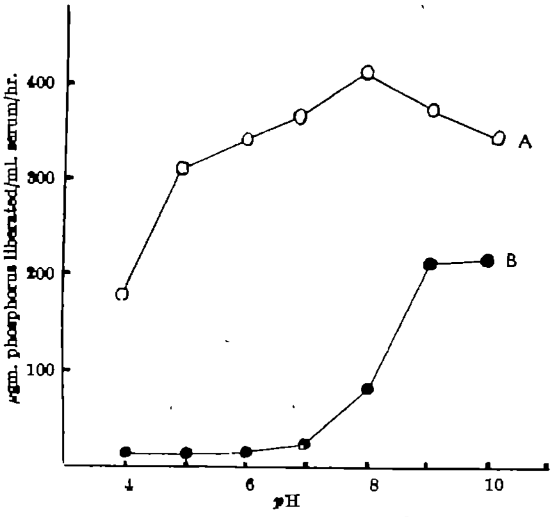
Serum 5-Nucleotidase

Reis[1-4] has demonstrated the presence of phosphatase in various tissues specifically hydrolysin 5-nucleotides, for example, adenosine-5-phosphat One of us has previously reported[5] that norm blood serum has a low 5-nucleotidase activity corr sponding to about 1/10 of its non-specific alkalin phosphatase activity towards glycerophosphate. I bone diseases where serum alkaline phosphatase raised, serum 5-nucleotidase may be normal; but i jaundice, either infective or obstructive, both enzyn levels may be increased, those of the 5-nucleotida sometimes exceeding those of the non-specific alkalin phosphatase.

The serum *p*H activity curves from a particul case of jaundice, having high 5-nucleotidase activit are shown here with adenosine-5-phosphate and β glycerophosphate as substrates, both at concentr tions of *M*/400 in barbitone buffer solution. Th hydrolysis of the adenosine-5-phosphate represen the sum of the 5-nucleotidase and non-specif phosphatase actions. These curves give further co



Hydrolysis of adenosine-5-phosphate and of β-glycerophosphate by blood serum of jaundiced patient (Pr.) at varying *p*H values. *A*, adenosine-5-phosphate; *B*, β-glycerophosphate rmation of the definite occurrence of this specific nucleotidase with an optimum at about pH 7·5 in ome sera.

Identification of Uric Acid and Ascorbic Acid by Chromatography

P. L. Kirk and E. L. Duggan[1] have described the lentification of various substances of clinical and iological importance, and we have published a uantitative micromethod for determination of urea[2]. n this communication we report on a colour reaction or uric acid and ascorbic acid in paper chromatography. It may be noted that F. Weygand[3] and . Prochazka and S. Koristek[4] have described the lentification of ascorbic acid with, respectively, lver nitrate and dichloroindophenol.

Our method is based on the property of uric cid and ascorbic acid of reducing ferric iron to rrous. With *o*-phenanthrolin hydrochloric acid the rrous ion gives a very sensitive red colour. The mples were applied to paper strips (Schleicher and chüll, paper No. 2043 *b*) and developed by the scending method in butanol/water/glacial acetic acid. fter drying, these strips were quickly immersed in solution of 5 ml. of ferriammonium sulphate (1·5 n./l.) and 45 ml. of *o*-phenanthrolin hydrochloric cid (20 gm./l.), and were then dried at 80–100° C. The following R_F values were obtained: uric acid, 18; ascorbic acid, 0·40. It is possible to identify 5 µgm. of uric acid.

The uric acid shows the red colour reaction at the ual place in the chromatogram of blood serum and ine. In the position of the ascorbic acid spot of re solutions the urine chromatogram shows regurly a second red zone which we could not identify r certain as ascorbic acid.

The red-coloured substances were eluted from the per strip with methanol, and measurement with Beckman spectrophotometer (model *DU*) gave an sorption maximum of 510 mµ. On measuring e optical density of the eluate from the zone of the ot against the eluate of the same height from a rip to which no substance was applied, a relation tween concentration and optical density was obined which was of the same type as a saturation rve.

Gaseous Contamination of Geiger–Müller Counters

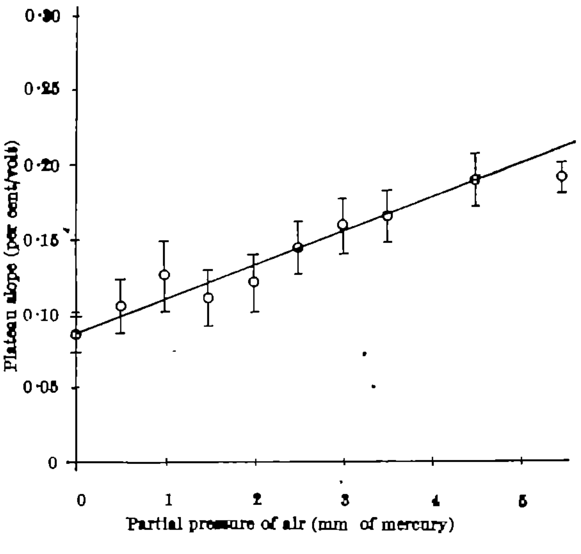
Although it is well known that the characteristics of Geiger counters may be very strongly affected by the presence of contaminated gases in the counter filling, very little quantitative work has, apparently, been published on the subject. In an experiment on extensive air showers in cosmic radiation, in which large metal-cased counters were to be used, it was desirable to know the quantities of gaseous contaminants which could be tolerated in the filling. The papers of Spatz[1], and of Korff and Present[2], include some quantitative data which were not, however, directly applicable in this case. Tests were therefore made of the effects of air and carbon monoxide as contaminants in ordinary glass-cased counters.

Standard Cintel cosmic ray counters were used, 50 cm. long and 4 cm. in diameter, with tungsten anodes and copper cathodes. The filling used was 10 cm. pressure of argon with 2 cm. of ethyl alcohol. Plateaux were plotted with a scaler, using the total flux of cosmic radiation at sea-level as a source. Counting-rates on the plateaux were approximately 520 counts/min. Operating potentials were in the range 1,200–1,400 volts. A stabilized power-pack was used.

In agreement with the work of Fenton and Fuller[3], plateau characteristics could not be reproduced exactly on successive fillings of a given counter. It was therefore necessary to add small quantities of the contaminant gases cumulatively to the same filling. This was done by means of a small gas-lock in the system, which could be evacuated separately from the counter, then filled at any desired pressure with the contaminant gas, and opened into the counter.

On first filling a counter, it was found necessary to leave it for about twenty-four hours before it had settled sufficiently for a plateau to be plotted. After adding contaminant from the lock, the system was also left for some hours so that equilibrium could be reached.

Both the length and slope of the plateau were affected by gaseous contaminants. The length of plateau is not, here, a good guide to the characteristic of the counter, since the slope increases with pressure of contaminant, and the criterion for the plateau



becomes less stringent. A better measure of the characteristic is the slope of the plateau, and this is plotted against pressure of contaminant, for air, in the accompanying graph. The effect is approximately linear for small pressures of contaminant, but appears to reach saturation at about 1 cm. pressure of air. This presumably occurs when all the argon ions moving away from the anode undergo exchange of charge with oxygen or nitrogen atoms. The plateaux were originally about 120 volts long, disappearing completely when the partial pressure of air was about 1 cm. No permanent contamination effects were observed, a plateau comparable, though not identical, with the original, being observed on re-filling.

The effect of carbon monoxide was also observed, since this is a likely contaminant in counters the cases of which are made of cast metal. The effects on the length and slope of the plateau were remarkable, a pressure of 0·5 mm. of carbon monoxide being approximately equivalent to 6·0 mm. of air. The plateau disappeared completely at a pressure of 1·0 mm. of carbon monoxide.

The deterioration of methane-filled counters has been attributed by Farmer and Brown[4] to the deposition of heavy hydrocarbons on the electrodes. It is possible that this effect is enhanced in argon-alcohol counters by the formation of carbon monoxide in the gas.

Effect of Variation in Diameter on the Torsional Vibration of Bars

During measurements of the resonant frequencies of torsional vibrations in cylindrical bars, it was observed that variation in the diameter of the bar along its axis caused the resonant frequencies to depart from a harmonic series. In order to relate the resonant frequencies to the shape of the bar, we have adapted a method described by P. M. Morse[1] for calculating the modes of vibrating strings in which the tension varies from point to point along the length.

The method consists in expressing the displacement of the bar at any instant as the sum of a series of normal modes for a uniform bar, and regarding the departure from uniformity as a small perturbation function imposed on the mean bar diameter. Substituting in the wave equation for a non-uniform bar :

$$\frac{\partial}{\partial x}\left(a^4 \frac{\partial \theta}{\partial x}\right) = \frac{a^4}{v_0^2} \frac{\partial^2 \theta}{\partial t^2},$$

where a is the bar diameter, x the distance along the axis, θ the angular displacement and v_0 the velocity of shear-waves in the material, and dropping out second and higher order terms, we obtain an approximate equation from which the coefficients of the series representing the bar displacement and also the modification to the resonant frequencies can be determin by a process analogous to Fourier analysis.

The result obtained in this way shows that, if t departure of the bar from uniformity is expressed

$$a = a_0 \left[1 + \sum_{p=1}^{\infty} K_p \cos 2\pi px/l + \sum_{p=1}^{\infty} C_p \sin 2\pi px/\right.$$

then the fractional change in the frequency of t mth harmonic is $-2K_m$. It will be observed th to the order of accuracy of this analysis the frequenc are unaffected by the sine components of the seri Thus, for example, a bar having a uniform ta along its length will have the same torsional resona frequencies as a uniform cylindrical bar.

In order to verify this result, we measured t resonant frequencies on a bar of aluminium appro imately 4 in. long by ½ in. diameter, the diamet being reduced abruptly between points $l/4$ and 3 distant from one end, where l is the length of t bar, to a value 4 per cent less than that at the en of the bar. The coefficients of the series representi the radius of the bar are then given by :

$$K_p = (-1)^{(p-1)/2}\, 0{\cdot}16/\pi p \text{ for } p \text{ odd}$$
$$= 0 \text{ for } p \text{ even.}$$

Table 1 shows the observed and calculated valu of percentage frequency deviation from the me value.

Table 1

Harmonic No.	Observed frequency deviation (per cent)	Calculated frequenc deviation (per cent)
1	−5·1	−5·1
2	0·0	0·0
3	+1·8	+1·7
4	0·0	0·0
5	−1·0	−1·0
6	0·0	0·0
7	+0·80	+0·73
8	0·0	0·0

A similar analysis of the effect on longitudinal wav predicts half the above deviations, since a enters t wave equation to the second power instead of to t fourth as in torsional vibration ; but such an analy ignores the effect of lateral inertia, which modif the vibrations by an increasing amount as the ra of bar diameter to wave-length (λ) increases[2] Measurements confirm this divergence between sim theory and practice, as Table 2 shows.

Table 2

Harmonic No.	$\frac{2a}{\lambda}$	Observed frequency deviation (per cent)	Calculated frequenc deviation (per cent)
1	0·061	−2·6	−2·6
2	0·123	0·0	0·0
3	0·184	+0·9	+0·9
4	0·245	+0·1	0·0
5	0·307	−0·4	−0·5
6	0·368	0·0	0·0
7	0·429	+0·2	+0·4
8	0·491	0·0	0·0

Failure of Vacuum Insulation at Low Field Strengths

PRE-BREAKDOWN currents in vacuum-insulated ystems are usually regarded as due to field emission. the electrodes are not subjected to heat treatment, owever, these currents occur at unexpectedly low eld strengths. We have recently examined a form f conduction at 10–150 kV. D.C. across gaps of a few ntimetres in continuously evacuated systems. The urrent is in this case distinct from field emission ecause (i) it is critically dependent on anode conditions, and (ii) the voltage required is only slightly hanged by large variations in gap-length. Other haracteristics of interest are that the current is selfxtinguishing, after a charge of the order of microoulombs has crossed the gap, with only slight drop n voltage; and that the voltage required may be ncreased by factors up to 2 by increasing the pressure f residual gas in the system.

The mechanism of the conduction is still being nvestigated; but it is clear that there is a resemblance to the 'electron loading' experienced in accelerating tubes in the megavolt field. It is hoped to ublish a detailed report shortly.

We wish to thank the Director of the Atomic nergy Research Establishment, Harwell, and the Ministry of Supply for supporting the work and for ermission to publish the results.

Definition of Chromatography

THE belief that the word 'chromatography' was oined by Tswett[1] about 1906 is incorrect; it appears o have been widely used, though with a different onnotation, for more than a century and a half reviously. As so often happens, Tswett appears erely to have adopted an existing word and given t an additional meaning. Paradoxically, many odern works of reference define chromatography in very way but the one which would first spring to he mind of a chemist.

In 1731, Bailey[2] defined chromatography as a reatise on colour; in 1835, Field published a book ntitled "Chromatography"[3]. As recently as 1949, unk and Wagnall[4] defined chromatography in he same sense and used 'chromatograph' to denote n instrument employed to produce different colours y rotation of a parti-coloured disk. In 1860, Holmes sed 'chromatograph' as a verb meaning to represent n colour[3].

Tswett probably derived 'chromatography', and e allied 'chromatographic' and 'chromatogram', rough the word 'chromatology' used by Sorby[5], ith whose work on the differential partition of igments he was certainly familiar, as he quotes it. echmeister and Cholnoky[6] later characterized swett's principal separation process exclusively as hromatographic adsorption analysis', but, as Koshyants and Kalmykov[7] have recently pointed out, swett recognized the possibility of applying his echnique more widely than by merely forming oloured zones in simple adsorption columns.

So many processes are now by common consent ccepted as forms of chromatography that an unequivocal definition of the word in its present chemical sense presents difficulties. We have proposed the following. "By chromatography is meant those processes which allow the resolution of mixtures by effecting separation of some or all of their components in concentration-zones on or in phases different from those in which they are originally present, irrespective of the nature of the force or forces causing the substances to move from one phase to another"[8,9]. This definition embraces not only the various forms of chromatography hitherto achieved but also all forms which have been postulated as theoretical possibilities.

FORTHCOMING EVENTS

(*Meeting marked with an asterisk * is open to the public*)

Monday, September 22

INSTITUTION OF MINING AND METALLURGY (at the Royal Institution, 21 Albemarle Street, London, W.1), at 5 p.m.—Prof. A. M. Gaudin : "Radioactivity in Mineral Dressing" (Third Sir Julius Wernher Memorial Lecture).

Monday, September 22—Thursday, September 25

NORTH OF ENGLAND INSTITUTE OF MINING AND MECHANICAL ENGINEERS (at Neville Hall and King's College, Newcastle-upon-Tyne).—Centenary Meeting.

Tuesday, September 23—Thursday, September 25

INSTITUTION OF MINING AND METALLURGY (at the Imperial College of Science and Technology, Prince Consort Road, London, S.W.7).—Symposium on "Mineral Dressing".

Wednesday, September 24

TEXTILE INSTITUTE (at the Lesser Free Trade Hall, Peter Street, Manchester), at 9.30 a.m.—Conference on "Factors in Plant Development".

INSTITUTE OF RURAL LIFE AT HOME AND OVERSEAS (at the National Society for Religious Education, 69 Great Peter Street, London, S.W.1), at 5.30 p.m.—Mrs. G. M. Culwick : "Social Development in the Gezira".

Wednesday, September 24—Friday, September 26

NATIONAL SMOKE ABATEMENT SOCIETY (at the South Parade Pier Portsmouth).—Nineteenth Annual Conference.

Thursday, September 25

EAST MALLING RESEARCH STATION (at the Laboratories, East Malling), at 3 p.m.—Prof. H. B. Tukey : "Research Developments in Fruit Culture in America" (Amos Memorial Lecture).*

Thursday, September 25—Saturday, September 27

INSTITUTE OF BIOLOGY (at the Royal Institution, Albemarle Street, London, W.1).—Symposium on "The Biology and Productivity of Hot and Cold Deserts".

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned :

ASSISTANT PHYSICIST (with an honours degree in physics)—The Secretary, London Hospital, Whitechapel, London, E.1 (September 27).

CHEMIST (with a degree in chemistry, and preferably some textile experience) for research on problems related to the dyeing and finishing of knitted products—The Secretary, Hosiery and Allied Trades Research Association, Thorneywood House, 4 First Avenue, Sherwood Rise, Nottingham (September 27).

EXPERIMENTAL OFFICERS in Ministry of Supply research and development establishments (most posts concern guided weapons, and require knowledge and experience of electronics)—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting A.253/52A (September 27).

ASSISTANT IN VETERINARY PHYSIOLOGY, an ASSISTANT IN THE DEPARTMENT OF ANIMAL HUSBANDRY, and an ASSISTANT IN BIOCHEMISTRY—The Assistant Secretary of University Court, The University, Glasgow (September 30).

PROFESSOR OF ETHICS AND POLITICS, a PROFESSOR OF ELECTRICAL ENGINEERING, and a LECTURER IN ELECTRICAL ENGINEERING—The Secretary and Bursar, University College, Dublin (September 30).

ASSISTANT SCIENCE LIBRARIAN (with a degree in a biological subject, library qualifications and special library or other bibliographical experience desirable) at London headquarters—The Director, Personnel Department, British Council, 65 Davies Street, London, W.1 (October 1).

EXPERIMENTAL OFFICER IN THE MECHANICAL ENGINEERING RESEARCH LABORATORY (D.S.I.R.), East Kilbride, Glasgow, for research work on plastic deformation of metals occurring in commercial processes, for example, rolling, drawing and forging—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting A.153/52A (October 4).

RESEARCH FELLOWSHIP IN THE DEPARTMENT OF NUCLEAR PHYSICS, Australian National University—The Administrative Officer in the U.K., Australian National University, 37 Russell Square, London, W.C.1 (October 10).

LECTURER IN ELECTRICAL ENGINEERING (preferably with experience in electronics or communications engineering)—The Registrar, The University, Sheffield (October 11).

CHAIR OF GEOGRAPHY at Victoria University College, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (October 31).

UNIVERSITY RESEARCH FELLOWSHIP IN INDUSTRIAL METALLURGY—The Secretary, The University, Birmingham 3 (October 31).

RESEARCH CHAIR OF WOOL TEXTILE ENGINEERING—The Registrar, The University, Leeds 2 (November 10).

EXPERIMENTAL OFFICER IN RADIO DEPARTMENT, Royal Aircr Establishment, Farnborough, for experimental design of aircr aerials for modern high-speed aircraft—The Ministry of Labour National Service, Technical and Scientific Register (K), Almack Hou 26 King Street, London, S.W.1, quoting D.352/52A.

LECTURER IN ELECTRICAL ENGINEERING—The Registrar, T University, Nottingham.

LECTURER IN ZOOLOGY—The Secretary, Royal Technical Colle Glasgow.

PRINCIPAL OF THE MID-ESSEX TECHNICAL COLLEGE, Chelmsfor The Chief Education Officer, County Offices, Chelmsford.

PRINCIPAL OF THE NORTH-EAST ESSEX TECHNICAL COLLE Colchester—The Chief Education Officer, County Offices, Chelm ford.

RESEARCH ASSISTANT for physico-organic researches IN THE CHEMIST DEPARTMENT—The Assistant Secretary, British Coal Utilisati Research Association, Randalls Road, Leatherhead, Surrey, quot Ref. A.37.

MAN-POWER IN SCIENTIFIC RESEARCH AND DEVELOPMENT

THE tenth report of the Select Committee on Estimates for the Session 1951–52*, dealing with rearmament, covers several matters of special interest in connexion with scientific man-power. It will be recalled that the Estimates Committee for the 1946–47 Session, reviewing expenditure on research and development generally, made some recommendations for correcting certain weaknesses revealed by the inquiry, which had paid particular attention to the question of atomic energy. The Defence Research Policy Committee had then only recently been constituted; but the statement on the functions of that Committee and the note by the Ministry of Supply on research and development in atomic energy appended to that report were supplemented by the evidence which Sir Henry Tizard gave to the Select Committee. Afterwards, in evidence before the Estimates Committee for the 1948–49 Session, Sir Henry expressed the opinion that the Defence Research Policy Committee was a satisfactory co-ordinating body and one that would improve: it was working well and its influence had increased. He did not believe that there was then any unnecessary overlapping in research between the Ministry of Supply and the Admiralty.

This was the report in which the Estimates Committee was severely critical of the omission of details of expenditure on research and development from the Defence Budget and the Estimates, supporting the views of the Estimates Committee of 1946–47; and Sir Henry Tizard himself indicated that he would welcome the opportunity of being able to speak quite frankly to a special committee set up to satisfy Parliament in further detail as to expenditure on research and development. The Estimates Committee also announced in that report its intention of inquiring further into the matter. The present report, however, does not pursue the question of expenditure directly, although its inquiry into man-power problems, and particularly into scientific staff and into the design and research establishments, bears closely on the implied question, which is even more important to-day when research and development work desired by the Services can only be undertaken at the expense of resources equally needed for productive purposes in Britain's economic recovery.

The Estimates Committee of 1946–47 noted that the principal needs were for men and accommodation. These, rather than lack of money, were holding up the pursuit of profitable lines of research. In the present report, the Committee finds that, apart from some difficulty in obtaining skilled labour, the man-power situation is reasonably satisfactory in both factories and research establishments engaged on the rearmament programme, except in regard to the call-up of apprentices and the supply of scientific staffs in government establishments. The Committee is not entirely satisfied with the present method of the call-up of apprentices, and it makes two specific recommendations. First, it recommends that apprentices should never be called up until their apprenticeship is completed. Secondly, it suggests the creation of some form of technical reserve, similar in its nature to the railway companies of the Royal Engineers, in which skilled men who have served their apprenticeship should carry out their military service. The Radio Industry Council suggested in evidence that the call-up of professional engineers and technicians should be limited to five months, followed by service in the Territorial Army for five and a half instead of four years.

---

* Tenth Report of the Select Committee on Estimates, 1951–52. Rearmament. Pp. xi+148. (London: H.M.S.O., 1952.) 6s. net.

It could fairly be deduced from the minutes of evidence taken before the Committee that its tenth report does not refer more specifically to expenditure on defence because the security curtain is used by officials to avoid pertinent questions. Sir Ralph Glyn's remark on another occasion: "There has been more extravagance in expenditure due to documents being labelled 'Secret' than from any other single cause. . . . The word secret is very often applied in order to cover up extravagance", is worth remembering. It is the more imperative, therefore, to ensure that every possible means of avoiding waste of trained man-power should be examined, and no excuse of administrative inconvenience can be accepted as reason for not exploring such suggestions.

The second matter, that of the shortage of scientific staff, particularly in the lower grades, which is due to some extent to the higher salaries which young men can obtain in industry or in posts overseas than in the government service, with consequent turnover of staff, deserves more consideration, and the minutes of evidence on this point are of considerable interest. When the Estimates Committee of 1946–47 reported that the new salary scales proposed for the Scientific Civil Service, and the ability to transfer pension rights, coupled with the conditions of service, offered a reasonable prospect of attracting sufficient scientific staff of the requisite calibre, Dr. Cockcroft, as he then was, expressed himself as satisfied with the scales in general although higher salaries were paid in industry. In the interim, those salary scales have fallen further behind those existing elsewhere, and evidence supplied to the 1951–52 Committee plainly shows that responsible and highly trained scientific men employed in posts requiring exceptional ability are seriously underpaid in relation to the importance and responsibility of their work and of their capacities, and in relation to the exceedingly costly capital equipment for which they are responsible.

It was stated, for example, that the Department of the Controller of Guided Weapons and Electronics, Ministry of Supply, is experiencing difficulty in recruiting sufficient scientific workers, as opposed to mechanical, electrical and electronic engineers, to meet the Services' requirements in research and development. At the National Aeronautical Establishment at Bedford, difficulty is expected in obtaining sufficient technical staff due to Government policy in regard to staffing. Vacillation in the policy of staff recruitment was regarded as very detrimental to t recruitment of the best possible men.

Subject to that reservation, the Select Committ on its visit to Bedford found no doubts as to t ability of that establishment to attain the hig intellectual standard characterizing the Royal Ai craft Establishment staff at Farnborough. It w emphasized that, although the scientific man naturally concerned to some extent about salary, attaches great importance to the provision of firs class facilities for carrying out his research. Accor ingly, many men who could command salaries industry as much as double those they receive in t government service choose to remain because of t excellent facilities they are afforded. Apart fro equipment, the aim is to provide the intellectu freedom that is necessary, and in the main, Prof. A. Hall, director of the Royal Aircraft Establishmen claims that the effort has been successful.

The evidence given before the Select Committ casts some doubts on Lord Cherwell's contention the House of Lords before he took office that a alternative form of organization outside the Civ Service would offer some advantage in dealing wit developments like atomic energy, and particular such an establishment as Harwell. Conditions ther as evidence submitted to the Select Committee mak plain, differ from elsewhere. At Bedford, the tur over of scientific staff was estimated as about fi per cent per annum. The corresponding figure f Harwell appears to be about ten per cent; b although the university aspect of that establishme was stressed in evidence before the Committee a in a memorandum submitted by the Ministry Supply, the wastage of scientific officers from oth atomic energy establishments is no higher than th from other defence research establishments, and th from Harwell amounted to no more than twenty-fo officers a year in 1950 and 1951. Harwell, in fa has been regarded as something in the nature of technical university. Its unique facilities for traini workers in the problems and techniques of nucle research naturally attract to it a number of you men who look upon it as a necessary stepping-sto in their selected career of scientific work.

Nevertheless, the wastage of staff at Harwell only comparable with the output of postgradua students from a university, and the attraction working at least for a period in a novel field under scientist with a world-wide reputation to some exte offsets the inability to offer exceptional salary scal to attract outstanding men, but which it would difficult to justify within the Scientific Civil Servic The staffing position for the atomic energy proje does not at present cause undue disquiet; b equally the Ministry of Supply admits that it is n a matter to be viewed with complacency. On th point the Select Committee, which is satisfied th the equipment in government research establishmen is of the highest quality and that it is important ensure that the men recruited to use this equipme are of like quality, recommends that the scales salary and conditions of employment should be ke under constant review.

This is only common prudence, in order to secure e full return from the large sums of public money ready allocated to schemes of scientific research d development; but although there is welcome vidence in this report that the importance of con- tions of service and of securing contented teams of illed staff are more widely appreciated than when e Barlow Committee reported, there is evidence so of waste through neglect of this consideration. he Committee refers, for example, to the probability at the proposed transfer of the Fighting Vehicles esign Establishment to a fresh site will involve not nly a large waste of public money but also the reak-up of a valuable team of scientific experts.

The Select Committee fully recognizes the diffi- ulties which may sometimes be encountered in voiding costly decisions of this type. The risk, too, at expensive constructional work may be rendered ut of date by scientific discoveries made before the ork has even been completed cannot always be xcluded. Apart from the secrecy issue already entioned, the Select Committee's report is on the hole reassuring, and even where the secrecy curtain as most baffling, it appears to be satisfied that the oney spent on the atomic energy project is justified y the results so far achieved. Nevertheless, the arnings given in this report are plain enough, and ufficient material should now be available for ientific men to make sure by their professional ction that the position does not deteriorate.

Some other points in this report merit notice. vidence was submitted of the need for greater ttention to the function of the technical colleges in roviding technicians—a function commonly ignored discussions on technological education. It was stimated, however, that only some 1,750 technicians ould be required for research and development in e rearmament programme, instead of the 3,000 stimated by the Hankey Committee.

Sir John Cockcroft's evidence before the Com- ittee is of special interest. He estimated that about ne-third of the effort at Harwell could be broadly escribed as research and the remainder as develop- ent, including about 15 per cent on the production f isotopes. The demand for these is rapidly in- reasing, and it has since been announced that Great ritain is now the world's largest exporter. Sir John lso expressed the opinion that the numbers and uality of staff recruited for atomic energy work are tisfactory, although it is the younger men rather an the older who are being attracted. He was not isturbed at a wastage of scientific staff running to n per cent. What is disturbing, however, is the ference elsewhere in the evidence before the Com- ittee to a drift of highly qualified men of science om Britain to America, attracted by the much igher salaries offered there.

This loss is not great at the moment: it was put t about fifty last year; but the loss of even that umber of our best brains is nevertheless a serious x on our limited resources of scientific and technical an-power, and the evidence of the Controller of tomic Energy on the disparity of salaries in Britain d overseas is not reassuring in this connexion. The Ministry of Supply's evidence on scientific staffing admitted that the scientific man entering the government service is probably underpaid in comparison with industry—as is also the scientist at the top of an establishment; it is contended, nevertheless, that the men in the middle range compare favourably in salary and conditions with those elsewhere. Sir Frederick Morgan, however, was prepared to argue a case for special scales for those on atomic energy work. He maintained that the man who is capable of original thought and of reducing it in a disciplined way into something which is handed over later to the production side is invariably on a scale of wages which bears no relation to the value of the work he is doing.

This report clearly emphasizes the danger of failing to get full returns from Britain's huge expenditure on research equipment through parsimony in the conditions offered to the men who use that equipment; nevertheless, it will fully justify the Committee's careful inquiries. No less important, however, is its warning of the dangers which also attend the use of the cloak of secrecy to hamper Parliamentary scrutiny of expenditure on research and development. Public scrutiny remains the surest safeguard against either extravagance or duplication of effort, and other evidence of Sir Frederick Morgan rather offsets Sir Henry Tizard's confidence as to the effectiveness of the Defence Research Policy Committee in this regard. His evidence led the Select Committee to correct its earlier impression that that Committee and the Advisory Council on Scientific Policy covered the whole field of research and development. In a strictly formal sense, atomic energy stands apart from the field covered by those two committees, and the complicated position disclosed by the evidence set forth in this report suggests that the position is not entirely satisfactory. Something more appears to be required in the way of co-ordination, even informally, before the organization of Britain's research and development effort can be regarded as adequate. The experience which Sir John Cockcroft brings from the atomic energy field to his new responsibilities as chairman of the Defence Research Policy Committee and of the Advisory Council on Scientific Policy should be a real help; but the need for fresh constructive thought here is as plain as is the need for limiting the use of the security curtain to the minimum consistent with national safety.

LOGICAL FOUNDATIONS OF PROBABILITY

Logical Foundations of Probability

By Rudolf Carnap. Pp. xvii+607. (London: Routledge and Kegan Paul, Ltd., 1951.) 42s. net.

PROF. R. CARNAP is one of the leaders in the modern school of mathematical logic. Perhaps his most striking contribution is his emphasis on the distinction between language and semantics (the theory of the meanings of the expressions in language). For example, Whitehead and Russell are said to have defined the number of a class as the class of all classes cardinally similar to the given class. (At least, this is the usual description of what they did; their actual procedure was more elaborate.) This is one interpretation of number. If it is supposed to be the only one, an ordinary mathematician appears to be precluded from using 'number' to mean anything else, even though other things may appear to follow the same rules. The modern method would be to consider a language containing the signs for the numbers—rules for manipulating the signs are stated in a further language called the metalanguage—and in this way a formal development of mathematics is created. The legitimacy of the interpretation of the signs and operations in a particular way becomes a separate problem. This idea can be applied to logical systems at the most elementary levels, and has led Carnap and others to considerable clarification of the foundations of logic.

The main theme of the present book is the application of this method to probability theory. Carnap distinguishes between two kinds of probability, which he denotes by probability$_1$ and probability$_2$. Both satisfy the same rules of manipulation. Probability$_1$ is regarded as a logical relation between pairs of statements expressible in a given language; probability$_2$ as a limiting relative frequency in an infinite series of experiments. An adequate account of scientific inference must include both. The discussions are very full on both the symbolic and the interpretative levels.

One difficulty of the subject is the distinction between 'subjective' and 'objective'. I have gone so far myself as to say that both words have been used in so many different senses that they should be abandoned as *nomina confusa*. Carnap's method enables him to say that both kinds of probability are objective. For probability$_1$, his argument permits him to avoid the term 'degree of rational belief', on grounds similar to those given by Russell for deductive logic. Russell argued that $2 + 2 = 4$ is a logical relation between sets of classes and has nothing to do with the existence of a mind, rational or not, to appreciate it. The ability of a mind to understand and use it belongs to the interpretative level. Similarly, Carnap would regard probability$_1$ as a ratio of measures of sets of sentences and call it a 'degree of confirmation'; this is *used* in rational belief but is not its whole content. This seems to add some clarity. However, as he himself points out, the measures can be taken in many ways; his theory gives rules that must be satisfied by any system of probability$_1$, but many different numerical assessments would satisfy the rules, and the decisions between them need further discussion on the interpretative level. Most of the argument is quite general, and many controversial questions are well discussed.

Carnap discusses one particular assessment, which appears to be equivalent to Laplace's principle of indifference, and remarks that in some circumstances this leads to contradictions. A second volume is in preparation and will apparently produce more specific results. Some of these are described in an appendix, which states a modification of the principle of indifference to avoid contradictions. This seems similar to the rule that I have stated for the sampling of a population with respect to more than two exclusive properties. I doubt, however, whether this can cover the ground. Carnap does not appear to mind the conclusion (given by Laplace's form) that the initial probability of a general law, applied to a infinite class, is zero; and there is something to b said for that view. But Laplace's form also leads t the conclusion that if an event has succeeded in trials and failed in none, the probability that it w succeed in all the next $n + 1$ trials is ½, and this seem definitely too low to correspond to scientific practic The modified rule appears to intensify this difficult I hope that Carnap will attend to this point, becaus I know of nobody better equipped to produce satisfactory solution.

The book has not much to say about probability except that values of probability$_1$ are often estimat of probability$_2$. I am inclined myself to think tha the idea of an intrinsic probability is useful, thoug I think that the attempt to define it in terms of limiting frequency creates more difficulties than solves, and I cannot see that anything in the boo depends on the definition. It might be argued tha the only cases of probability$_2$ are in quantum physics one, for example, would be the probability that radium atom will disintegrate in the next minute. I coin-tossing, we might make a definition in terms o a limiting frequency (assuming it to exist) for sequence of throws with one coin (assuming that th coin never wears out), or in terms of one throw eac for an infinite set of coins (again assuming the limi to exist). But there is no way of proving that th two definitions would give the same assessment without piling up further assumptions that appea no more plausible than the notion of an intrinsi probability seems to begin with.

The book is far the best analysis of the logic o probability that has yet appeared, and will b indispensable to students of the subject. The specifi applications announced for the second volume will b awaited with interest.

HAROLD JEFFREYS

ORGANIC CHEMISTS' VADE-MECUM

Chemistry of Carbon Compounds

A Modern Comprehensive Treatise. Edited by Dr E. H. Rodd. Vol. 1, Part *A*: General Introductio and Aliphatic Compounds. Pp. xxiii+778. (New York and Amsterdam: Elsevier Publishing Co., Inc.; London: Cleaver-Hume Press, Ltd., 1951.) £7.

THE hiatus existing between the necessarily highly selective and simplified text-book treatment of organic chemistry and the comprehensive scope of compendia such as "Beilstein" has for long been filled by Richter's "Chemistry of Carbon Compounds". The last edition in English of this work appeared thirteen years ago, and even this was a patchwork overhauling of an earlier version. The need for a successor has been markedly apparent, and the onus of this task has been accepted by the Elsevier Publishing Co. in consultation with an advisory committee of six distinguished British organic chemists headed by Sir Robert Robinson; the herculean task of editorship is being shouldered by Dr. E. H. Rodd. The present book represents the first stage in the compilation of a five-volume work to take the place of "Richter" in providing a modern comprehensive treatise on organic chemistry.

The book opens with an editorial historical survey and sections on the classification, nomenclature and iterature of the subject. There follows a description f the quantitative analysis of organic compounds ; s this is written by a practitioner of the art, Mr. R. elcher, there is a welcome absence of description of he obsolescent apparatus and procedures beloved of nany other text-books. The striking infiltration of hysico-chemical ideas and techniques into organic hemistry is reflected in the contents of the next two undred pages, which are devoted to an exposition f the underlying theory of the science. This subject as been handled by the allotment of a section to very important topic, each being dealt with in essay orm by an expert in that field. Thus the discussion f free radicals and homolytic reactions is in the ands of Prof. D. H. Hey and Dr. W. A. Waters, tereochemistry is expounded by Prof. E. E. Turner, nd the crystallography of carbon compounds is lescribed by Dr. A. F. Wells. A review of the physical roperties used in the investigation of organic comounds is given by Prof. H. D. Springall, who also leals with modern concepts of acids and bases in heir relation to organic chemistry. The section on ight absorption, by Dr. E. A. Braude, is a succinct ccount of the theory and practice of ultra-violet and nfra-red spectroscopy and includes useful charts of he characteristic infra-red frequencies associated vith a large number of organic groupings. An uthoritative article on reaction mechanisms, by Prof. E. D. Hughes, contains the gist of the modern vork on the subject, written as it is by one who has nade large contributions to this study. Very little eference is made, however, to the alternative view f anionotropy as an essentially acid-catalysed proess ; it is surely a little ungenerous to dismiss this onsiderable body of carefully executed work in a wo-line footnote. Owing to the unavoidable comression of this wide topic, the full benefit of this section will accrue to those who already have some cquaintance with the subject.

No attempt has been made to include a detailed ccount of the twin concepts of valence bond and nolecular orbital treatment as applied to organic ompounds, beyond a brief description in the hisorical section. This is a sensible decision ; the ubject does not lend itself easily to compression, nd the recent publication of Prof. C. A. Coulson's nonograph on this topic renders any such treatment edundant.

The remainder of the book is taken up with its rimary task of systematically presenting the known acts of aliphatic chemistry. The exposition deals vith hydrocarbons and their halogen derivatives, lcohols and their sulphur derivatives, amines, rgano-metallic compounds, carbonyl compounds, arboxylic acids, glycols, hydroxycarbonyl and licarbonyl compounds ; the remaining aliphatic ypes will be dealt with in Vol. 1 *B*. Sound arguments r retaining this Richter classification are presented the preface, and indeed no difficulty is experienced finding any required section.

This enormous mass of information is laid out in a ucid and concise manner, clarity being greatly nhanced by the extensive use of tabulation. The xposition succeeds admirably in its aim of rendering asily available the accumulated knowledge of rganic chemistry ; a striking feature is the wealth f up-to-date leading references both to the original iterature and to review articles. Ease of reference is reatly enhanced by the provision of a truly magnificent index, for which grateful tribute must be aid to the editor.

The production of the volume is of the excellence one has come to expect from Elsevier, and the book is a pleasure to handle. The errors are surprisingly few for a work of this range, and such as do occur in the text are typographical trivialities. It is unfortunate, however, that the first entry of tropolone into a text-book should be heralded by a badly malformed structural formula. The price of the book is not excessive in view of its content, and a 15 per cent reduction is allowed both for this and the following volumes if they are ordered prior to publication. The debt already owed by organic chemists to these publishers for their very fine encyclopædia is further increased by their presentation of this authoritative work.

CONVEYING OF HEAT ENERGY

Elements of Heat Transfer and Insulation

By Prof. Max Jakob and Prof. George A. Hawkins. Second edition. Pp. xvi+230. (New York : John Wiley and Sons, Inc. ; London : Chapman and Hall, Ltd., 1950.) 32*s*. net.

IN the preface to this second edition of their book, the authors remind us once more that the subject of conveying heat energy is not of less importance than that of converting it. Many would consider this an under-statement, for not only do heat transfer problems confront the practising engineer more frequently than thermodynamic ones in many fields, but also their solution is more difficult and often requires an intuition of what aspects are vital and what may be neglected, which only experience based on theoretical understanding can provide. However, in universities it is not yet usual to accord the teaching of heat transfer equal status with that of thermodynamics, partly no doubt because the former subject is comparatively new, but partly because of the lack of suitable text-books for undergraduates. Profs. M. Jakob and G. A. Hawkins have set out to make good the lack.

As usual, they divide heat transfer into three parts—conduction, convection and radiation although they do have chapters dealing with the combined effects of all three modes. The main emphasis is on the first of these, and there are excellent simple accounts of the application of relaxation and graphical methods to those problems in heat conduction, both steady and unsteady, which are too difficult for mathematical analysis. Although these matters are often considered 'advanced', the clarity with which they are presented brings them well within reach of the undergraduate. A large amount of useful data on thermal conductivities is provided.

The treatment of convective heat transfer is more sketchy. Despite the authors' statement that forced convection is probably the most important method of heat transfer, only five pages are devoted to it, and these contain little more than a bald presentation of the empirical relations between the dimensionless groups for flow inside and outside tubes.

The dimensionless groups are derived by the algebraic method. This has the disadvantage that their physical significance is not apparent, a disadvantage, however, which appertains not to dimensional analysis, as the authors assert, but to the algebraic presentation of it. Many students find more illuminating the alternative derivation of, say, the Reynolds number as the ratio of inertia to viscous forces, and of the Grashof number as the ratio of buoyancy to viscous forces.

The authors suggest that the theory of convective heat transfer based on the surface film concept of Langmuir and Rice is more "conspicuous". Yet this theory leaves unanswered the question of why such a film occurs, and how its properties must vary with the conditions of flow. It seems a pity, therefore, that space was not found for introducing the idea of a thermal boundary-layer and the heat-balance equation which determines its thickness. On the other hand, the authors have presented Reynolds's analogy between friction and heat transfer in a rather more detailed manner than usual; I feel that this thoroughness is not worth the resulting loss of clarity. The analogy is chiefly useful for rough but speedy calculations; when greater accuracy is needed, it is usually possible and preferable to turn to experimental results or more exact theory rather than to elaborations of the analogy.

The book contains a concise account of radiant heat-exchange between black and grey bodies; but gases and flames are not treated. The emphasis is on providing useful design data rather than the underlying fundamental relations. There is a short chapter on heat transfer in boiling and condensation, but mass transfer is dismissed in a sentence.

D. B. SPALDING

TEXT-BOOK OF PLANT GROWTH SUBSTANCES

Die Wuchsstofflehre

Ergebnisse und Probleme der Wuchsstofforschung. Von Prof. Hans Soding. Pp. xi+304. (Stuttgart: Georg Thieme, 1952.) 33 D. marks.

PROF. HANS SÖDING says that his aim in writing this book is to make a comprehensive presentation of all aspects of research on growth substances, set in their proper perspective in the wider field of plant physiology. To achieve this, he assumes the usual text-book knowledge of plant physiology; but where this is not sufficient to allow a clear exposition of his thesis, he touches on wider physiological problems. In addition to presenting results of published work (as far as 1949, with a few additions for 1950–51), he has attempted to indicate open questions and avenues for further exploration. In this he succeeds admirably.

The first two chapters are concerned with accounts of assay and extraction methods, including full details of Prof. Söding's own 'daylight curvature test', with data on magnitude of response and variability. Such data are useful for comparison with other methods of hormone assay.

Chapters on the distribution of growth substances in plants during development, the role of external and internal environment, auxin transport, tropisms, the role of auxin in cell division, root formation, etc., and the mechanism of auxin action, follow patterns similar to those in existing works in English on these topics. They are useful, however, for the inclusion of much recent Continental work, especially war-time German research, the original reports of which are not always readily available in English libraries.

To appreciate the chapters on extraction of auxins from plants and on the chemistry of growth-promoting and -inhibiting substances, some remarks on nome clature are necessary. The term 'growth substanc (*Wuchsstoff*) is defined as meaning substances (i cluding synthetic compounds) which increase exte sion growth of higher plants, especially the o coleoptile. Naturally occurring growth substanc are considered to be auxins *a* and *b*, with 3-indoly acetic acid (heteroauxin) acting probably as a activator of these substances in the plant. For th benefit of Continental readers, Prof. Söding poin out that in the English literature the term 'auxi denotes not auxin *a* or *b* but any of a range natural and synthetic growth substances, dependin on the context, though usually it refers to heter auxin.

That such explanations should be necessa emphasizes present-day confusion resulting fro indecision on the nature of growth hormones plants. The question whether these are auxins *a* an *b*, or 3-indolylacetic acid and related compounds, still *sub judice*. It must be admitted, however, th with the passage of time convincing evidence favour of the existence of auxins *a* and *b* in high plants becomes more slender, while proof (f example, by chemical identification and by enzymat studies) of the importance of certain indole com pounds as natural growth hormones increases. Muc of the evidence for the existence of auxins *a* and is based on acid- and alkali-stability tests on pla extracts (examples are listed on p. 74), and this wi now need re-examining in the light of the rece discovery of 3-indolylacetonitrile as a naturall occurring growth hormone.

The fact that indolylacetic acid can be extracte from many plant tissues, regarded by the majority British and American workers as strong evidence the importance of this substance as a naturall occurring growth hormone, is considered by Pro Söding to be the greatest weakness of extractio methods. He believes that indolylacetic acid b longs primarily to the protein metabolic cycle an not to the auxin cycle (p. 87), and that deductio about the growing system cannot be made wit certainty from extraction data (p. 23). This approac would seem to rule out the possibility of furthe experimental advance on the chemical side and t make the question of the identity of the natur auxins one which should not be asked.

Possibly the most valuable sections of the book f the English-speaking reader are those on the role auxins in correlative inhibition, polarity of regene ation and other aspects of morphogenesis, since these topics, which have been developed so extensively b German workers, tend to be neglected in British an American text-books.

There are two useful chapters on the positio occupied by growth substances in the hierarchy plant hormones and vitamins (*Wirkstoffe*), and th interactions of these substances in the plant.

In the concluding *Ausblick* the future develo ment of hormone research is discussed. With th increasing tendency to rely on the interpretation mathematical curves and figures, the subject becom ever more *vergeistigt*; but Prof. Soding hopes th the biologist of the future will see behind his figur the same beautiful and harmonious picture of Natu as the Nature-lover sees in the butterfly and th flower.

The book is expensive in British money, but i well produced, and would be a useful addition o plant hormones to any library.

J. A. BENTLEY

reeding Birds of Kashmir

By Lieut.-Colonel R. S. P. Bates and E. H. N. Lowther. Pp. xxiii+367+85 plates. (London: Oxford University Press, 1952.) 38s. net.

BEFORE the Second World War, Kashmir was a favourite resort of Europeans desirous of a hange from the heat of the plains to a cooler climate, wonderful scenery, beautiful flowers, and a great variety of birds. The authors are experienced field naturalists who have made a speciality in photographing birds in India and, in addition to making many studies in the plains, have devoted much time o Kashmir birds. The country they worked in lies between the great Himalayan range and the Pir Panjal range and is drained by the Rivers Jhelum and Kishenganga and the upper waters of the Vardwan River. The whole area consists of valleys with orchards, lakes and marshes, and, on the hillides, forests with bare screes above and upland meadows in the higher reaches.

With this great variety of habitats there is a corresponding variety of bird life. In the lower parts of the valleys there are a few oriental species from the plains of India, such as the magpie robin and he jungle babbler. Higher up there are the grey drongo and slaty-headed parakeet, both Himalayan species. Another plains bird is the pheasant-tailed acana, which is migratory and in the summer abounds among the lotus leaves of the numerous lakes; according to the authors, one was seen on a tarn at 12,050 ft., but they give no date. Of the palæarctic birds some are residents; but the majority descend to the Indian plains with the advent of autumn, while others do not go farther than the foothills of the Himalayas.

The volume is confined to the birds breeding in the area mentioned, and many species recorded as nesting in Kashmir are not included since they resort to the more bleak areas of Ladakh and Baltistan to breed. The habits and nests of 116 species are described, and when the authors have not sufficient experience they amplify their notes with extracts from the writings of other ornithologists.

This is a very interesting book, with a certain amount of new information which does not always agree with the accounts in Baker's "Identification of Indian Birds". There are eighty photographs of nests, birds and scenery, most of which are of a high standard, but this can scarcely be said of the coloured plates—the birds are stiff, and the colours have suffered in reproduction.

Études sur les scorpions

Par Max Vachon. Pp. 482. (Alger: Institut Pasteur d'Algerie, 1952.) 2200 francs.

THE determination of scorpions has for years been a puzzling task, because of the variation which many species show. For this reason M. Vachon has undertaken an intensive study of the scorpion fauna of North Africa, with a revision of their systematics and nomenclature.

He now offers us, first, a general account of the order, taken largely from his chapter in Grassé's "Traité de Zoologie", which will be welcomed by many who do not possess that expensive work. Secondly, he reviews the characters that can be successfully used in identifying a scorpion, emphasizing chiefly the trichobothria or *poils auditifs* on the appendages. There follow descriptions of the thirty-three species of North African scorpions which M. Vachon recognizes, with dichotomic tables summarizing the whole. It is a feature of these keys that they can often be used for mutilated specimens. M. Vachon has no hesitation in adopting a trinomial system for the many subspecies he establishes, nor to extend this by the addition of varietal names for forms which are often distinctive for special localities.

M. Vachon has included an account of the geographical distribution of these animals, and a discussion of their origin and dispersal. His book may be recommended as an impressive example of a truly biological survey of a limited group, almost a model for others engaged in similar work.

T. H. SAVORY

Mellor's Modern Inorganic Chemistry

Revised and edited by Dr. G. D. Parkes. Pp. xxi+967. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1951.) 25s. net.

THIS well-known text-book was revised and rearranged in 1939 by the late Prof. J. W. Mellor in collaboration with Dr. D. G. Parkes. Since then it has been several times reprinted; for this present edition the text has been once again reset. Up-to-date matter inserted here and there throughout the book accounts for thirty new pages. In addition, there is a new chapter (nine pages) summarizing the chemistry of the metals.

According to the preface of 1939, a guiding principle of the editors was the keeping of "a proper balance between theory and facts". However, revision of the theory is not of the same high level as that of the factual material. Resonance gets a paragraph in small print; the covalent and coordinate links get less than two pages of small print, and not one of these is sufficiently deeply expounded to make it readily applied. Thus in discussing boron fluoride, Dr. Parkes is not able to relate its structure and its intense activity. All the periodic tables end with uranium. The Bronsted-Lowry conception of acids is not mentioned.

Apart from these points, the revision has been well done, and the book retains those qualities which gained for it its high reputation.

G. F.

Sedimentary Petrography

With Special Reference to Petrographic Methods of Correlation of Strata, Petroleum Technology and other Economic Applications of Geology. By Henry B. Milner. Third edition, reprinted with a new Preface and Corrigenda. Pp. xix+666+52 plates. (London: Thomas Murby and Co., 1952.) 50s. net.

MILNER'S "Sedimentary Petrography" has been in use for many years as a text-book and standard work of reference in British universities. The second (first complete) edition was published as long ago as 1929, and an enlarged and completely revised third edition appeared in 1940. This has been out of print for some years and has now been reprinted. It is issued unchanged except for a page of corrigenda and a corrected and revised list of the British Standards quoted in the book. It is to be regretted, in view of the large amount of research carried out on the sediments in the past decade, that pressure of work has not permitted the author to complete the revised fourth edition that he has in hand. Nevertheless, the ground covered in the work as it stands is so comprehensive, including both descriptive matter and laboratory technique, that it will doubtless continue to provide a valuable introduction to the subject for university students.

NUCLEAR AND FUNDAMENTAL PARTICLE PHYSICS

AT the summer provincial meeting of the Physical Society, which took place in the Department of Natural Philosophy, University of Glasgow, during July 10–11, four main sessions were held and five main topics were considered from both the experimental and theoretical points of view. The president of the Society, Prof. R. Whiddington, was in the chair. The opening session dealt with the excited states of light nuclei, and in the afternoon the subject of π^0-mesons was discussed. On the morning of July 11 the chief topics were β-radioactivity and photo-disintegration, and in the afternoon a theoretical session on the *S*-matrix series was held. Discussion followed each session. The general opinion of all those participating was that the conference had proved very profitable indeed, and it had been a fitting occasion on which to use, for the first time, the new lecture theatre in the extension to the Department.

Excited States of Light Nuclei

Prof. P. I. Dee (Glasgow), in reviewing existing knowledge of excited states of nuclei, indicated the need for some principle correlating nuclear data. He illustrated in an original manner the severely limited field covered by most of the known methods for determining nuclear levels, which methods include neutron absorption, proton capture, β- and γ-activity, scattering, and the different particle reactions such as (*d*, *p*), (*d*, *n*), (*d*, α), (*p*, α) and (α, *p*). Detailed discussion of the measurement of γ-ray energy and the kinetic energy of particles was followed by consideration of resonance excitation. The absence of internal conversion has led to indirect methods of determining quantum energy; but accuracy is reduced (~ 0·1 MeV.). However, the situation is improving with the introduction of scintillation counters. For particle energies a large magnetic spectrometer is the most accurate (errors ~ 0·005–0·01 MeV.), but the low efficiency limits its application. Nuclear photo-emulsions offer a good solution, as shown by work at Bristol and Liverpool.

Regarding data on spin and parity, Prof. Dee considered that the methods are too tentative to be really satisfactory. The study of angular distributions is fruitful, and the method of internal pair creation, as used at Glasgow, seems to be of fairly wide application. It is his belief that as few as 10–20 states are known with complete certainty, and a brief review of the efforts to find regularities in the arrangement of levels leads to the conclusion that these are, at best, hopeful. A determined effort on the theoretical side, therefore, seems overdue.

Dr. J. G. Rutherglen (Glasgow) discussed mainly the resonances for the processes ^{27}Al (*p*, α) ^{24}Mg and ^{27}Al (*p*, γ) ^{28}Si, showing that three out of six observed are common, involving competition. In considering internal pair creation, as applied by Dr. E. R. Rae and himself to the study of γ-ray states, Dr. Rutherglen said that the low values of *I*, the internal pair coefficient (~ 10^{-3}), necessitate considerable care in estimating the number of positrons emitted. The estimation can be made with the magnetic spectrograph or by measuring the annihilation quanta produced on stopping the positrons. Tests with sodium-24 are in agreement with other methods, which show the transitions are electric quadrupol A new method of estimating the absolute number γ-rays by measuring the area under the spectrum Compton secondaries has been found useful when n β-rays are emitted, and the method has operate successfully for capture of γ-radiation (protons c fluorine).

The next speaker, Prof. H. W. B. Skinner (Live pool), discussed stripping reactions using 8-MeV deuterons, and showed how this has become a ver powerful method, of wide applicability, for findin the spins and parities of nuclear states. Early wo with photo-plates yielded valuable data but involve considerable labour in the analysis. More recentl differential ion chambers and proportional counte have operated successfully with (*d*, *p*) reactions, an moreover permit examination down to any sma angle relative to the beam. Both (*d*, *p*) and (*d*, reactions have been assumed to proceed by way of compound nucleus, but results, particularly at sma angles, contradict the early theory and suggest stripping mechanism. Comparison of angular di tributions with the theoretical predictions (based o theoretical studies at Birmingham and Liverpool show that spins and parities of states can be reliabl deduced. Prof. Skinner illustrated the technique wit many interesting examples, directing particula attention to the finding of a mixed state; the fir excited state denoted ^{27}Al, p_1, which was mainly *D* an partly *S* (*S*/*D* ~ 10 per cent). A kind of anti-strippin in which the bombarded nucleus 'seizes' a neutron for example, ^{9}Be (*d*, *t*), and the capture and loss o neutrons as suggested by examination of mag nesium-24, were discussed.

For (*d*, *n*) reactions, negative *Q* reactions are pre ferred rather than high positive *Q*, as for (*d*, *p*) Observations with nuclear emulsions show that i some cases neither theory fits. Finally, Prof. Skinne showed that the excited states of some mirror nucle (carbon- and nitrogen-13, oxygen- and fluorine-17 nitrogen- and oxygen-15, and sulphur- and chlorine 33) are well known, and he suggested that corre spondence between spins and parities is perhaps mor significant than that for energies.

Dr. C. A. Ramm spoke of his work at Birmingham in collaboration with E. R. Collins and C. B. Mac kenzie, in which precision measurements of the energ of particles produced with a Cockcroft-type magne have yielded accurate *Q* values for reactions. H discussed the sources of error in such experiment particularly for the reaction ^{7}Li (*p*, α) ^{4}He. Study o target deterioration has shown that some nove problems arise.

Prof. L. Rosenfeld (Manchester) brought th session to a close with an account of the theory o nuclear models and excited states. He began b stressing that, in attempting to explain the propertie of nuclear states, we are still very far from the idea set by the theory of atoms. In this the predominan influence of the Coulomb field introduces an elemen of simplicity entirely lacking in the nuclear case Moreover, our knowledge of the interactions betwee nucleons lacks the definiteness of the law of electric interaction. We cannot hope to deduce the propertie of nuclei from the mere knowledge of the number o constituent nucleons, and we must take over fron eriment as basic assumptions the existence of sed shells as indicated by the magic numbers. is is the clue leading to the Jensen–Mayer shell del in which the additional assumption is made of trong spin- orbit coupling with a sign such as to e rise to inverted doublets for the individual cleon states. One may expect that some at least the states of low excitation will correspond to the citation of a single nucleon in an incomplete shell. e properties of such excited states are immediately dicted by the model. In experiments involving onances, this type of excited state can be recog- ed by its having a larger width than those due to re complex modes of excitation.

Prof. Rosenfeld pointed out that direct experi- ntal evidence supporting the assumption of large n-orbit coupling is obtained in the scattering of cleons by helium. Here the spin–orbit separation served is ~ 5 MeV.

To improve the shell model it is necessary to estigate the result of the interactions of nucleons ich are neglected in the first approximation. This blem has recently made great progress in two ections: the discussion of the mutual interactions incomplete shells; and the interactions of these cleons with the core formed by the closed shells. e first problem has been treated on the assumption mainly central interaction between any two cleons. The stationary states have been classified methods of group theory, perfected by Racah, th for Russell–Saunders coupling (Jahn *et al.*) and *jj*-coupling (Flowers, Flowers and Edmonds). nerally, the conclusions are found to be very sitive to the assumptions made concerning the pe of the nuclear potential. The results of cal- ations by Talmi using a meson potential are com- tely different, as regards the order of succession the excited states, from those obtained using a ussian potential.

The problem of interaction between the incomplete lls and the nuclear core has been most fruitfully acked by Aage Bohr and Mottelson. The idea is t the interaction deforms the nucleus and excites llations on its surface. There appears to be a ong coupling between the angular momentum of incomplete shell and that of the deformed cleus. The predictions regarding the resultant gular momenta are then obtained by methods nparable to those used in molecular spectroscopy. both cases, comparison with experiment reveals ne discrepancies and shows the need for the next p, which should be to determine the combined ect of the two types of interaction described ve.

In the discussion following the first session, Prof. Peierls (Birmingham) made a number of important nts, and he deprecated the tendency to divide rply between theory and experiment. He thought t at present the most important step is to ask the ht question.

The π^0-Meson

n opening the afternoon session on meson prob- s, Prof. J. C. Gunn (Glasgow) surveyed π-meson ory in relation to experiment, and described the ral considerations from which the pseudoscalar racter of the π-meson can be deduced. In par- lar, detailed balancing applied to the reactions $+ p \rightleftarrows \pi^+ + d$ shows that π-mesons have zero spin, le the observed process $\pi^- + d \rightarrow 2n$ shows that y have odd parity, provided, as is plausible, capture of the meson takes place from a K-orbit. More detailed methods of approach were then considered by Prof. Gunn for some basic meson problems. Combined phenomenological and weak-coupling calculations indicate that mesons should be produced isotropically in the reaction $p + p \rightarrow \pi^+ + d$ (corresponding to capture of S-wave mesons in deuterium). In fact, a $\cos^2 \theta$ distribution is found. It is difficult to explain this disagreement except by the breakdown of the weak-coupling approximation. The reaction $n + p \rightarrow \pi^0 + d$ is to be noted as a powerful test of the 'charge independence' hypothesis for meson coupling.

The weak-coupling treatment of quantum production of mesons, and of meson nucleon scattering, again shows little agreement with experiment. It has indeed proved most profitable to apply the methods of partial wave analysis to data on meson–proton scattering. This confirms the idea that these particles interact so strongly that they can no longer be regarded as simple structures. The two theoretical approaches which are clear at the present time are the *ad hoc* assumption of isobaric states to fit the experimental evidence or the use of the intermediate-coupling method.

Dr. R. G. Moorhouse (Glasgow) described his investigations using the intermediate-coupling method. The nucleon is represented as a superposition of states containing the bare particle, together with arbitrary numbers of mesons and nucleon pairs in given configurations. The variables are the amplitudes with which these states occur. Two cases have been considered: when the surrounding cloud contains only mesons; and when it includes nuclear pairs and no mesons other than those introduced in the pair creation. The first case gives wrong magnetic moments for the neutron and proton; but the second is more promising as the magnetic moments differ in absolute magnitude by a nuclear magneton.

Describing recent experiments on the decay of π^0-mesons, B. M. Anand (Bristol) said that examination of a large number of jets has shown that the life-time T is less than 5×10^{-14} sec. King at Bristol has observed electron pairs arising apparently in the second of the two decay processes: (*a*) $\pi^0 \rightarrow \gamma + \gamma$, and (*b*) $\pi^0 \rightarrow \gamma + e^+ + e^-$. Process (*b*) seems to be the more promising, for the evaluation of T and a method of time dilation applied to the photo-plates have given $T \simeq 1 \times 10^{-14}$ sec. A study of some fifteen hundred stars of low energy gives the ratio 80 for the probabilities of (*a*) to (*b*). The energy distribution of direct to related pairs is $\overline{E}_a/\overline{E}_b = 0{\cdot}86 \pm 0{\cdot}26$, which apparently confirms the theoretical value 1·0, so that the energy is shared equally between the two electrons and the γ-ray. Finally, Mr. Anand spoke of single electrons appearing to come from stars and the origin of which in some cases seems to raise interesting queries.

Dr. R. H. Dalitz (Bristol) discussed his theory of decay of π^0-mesons. In addition to (*a*) and (*b*) above, he considered: (*c*) $\pi^0 \rightarrow e^+ + e^-$, and (*d*) $\pi^0 \rightarrow 3\gamma$, noting that (*d*) is forbidden by charge conjugation. His theory gives for the ratio of probabilities $(a)/(b) = 80$, confirmed by experiment. He stressed the connexion with internal pair conversion, which has a low probability ($\sim 10^{-4}$) at energies $\sim$ 1 MeV., as against 1/80 at the energies here involved.

The meetings for the first day of the conference closed with a discussion of the possible advantages of holding more conferences on nuclear physics. There seemed to be general agreement on the desirability of extra meetings, confined to specialized topics in the field.

Beta Radioactivity

Dr. S. C. Curran reviewed the theory of β-decay and passed to discussion of the results of the Glasgow group with proportional and scintillation spectrometers. He listed the possibilities of disagreement with straightforward theory, which might show in the low-energy region of β-spectra. Here the proportional tube containing gaseous sources, particularly when supported with the scintillation spectrometer, is nearly ideal. Among the possibilities is readjustment of the atom consequent on the change of atomic number in the emission process. Assuming the adjustment energy goes entirely to the electron, a displacement of the spectrum along the energy axis follows, giving a 'hole' at the low-energy end. Tritium shows such a 'hole', but it is too extensive to be explained as readjustment. Work on radium-*D*, mercury-203 and nickel-63 does not support the view that the electron receives the whole energy.

The central problem of determining the mode of interaction (or combination of modes) has been attacked by investigating highly forbidden transitions. Study of rubidium-87 (half-life, 6×10^{10} yr.) shows that both C_{3T} and C_{3V} correction factors give excellent straight lines. This work with the proportional tube has been confirmed closely by G. M. Lewis using crystals of rubidium iodide (thallium) as their own spectrometers. Recent results for rhenium-187 give the transition energy as about 400 keV. and suggest the transition is probably at least third forbidden. This implies that stable osmium-187 has a spin of 11/2 or 13/2, an unusually high value possible, however, on the shell model. Dr. Curran stressed the possible close association of this model with the natural radioactive sources. For potassium-40, rubidium-87, lanthanum-138, lutecium-176 and rhenium-187, or the daughter elements, there seems to be a connexion with the important shell numbers 20, 50, 80, 106 and 112 respectively.

The curved crystal spectrometer used recently to examine the γ-rays of radium-*D* was described by Dr. G. T. Ewan (Edinburgh). A very sharp line at 46·52 keV. was observed, corresponding to the known excited state of radium-*E*. No line corresponding to a state at about 43 keV. was observed. In view of the absence of other apparently established γ-transitions, upper estimates to their possible intensities were given. The new results show that the mode of decay in some 20 per cent of the disintegrations of radium-*D* is still uncertain.

Dr. D. L. Pursey (King's College, London) spoke on his recent work on the theory of β-decay. This is concerned with the experimental determination of interaction in the theory of decay. The spectrum shapes of allowed and first forbidden transitions and the *ft* values of super-allowed transitions lead to the conclusion that the interaction contains either both the scalar and tensor or both the polar and axial vector invariants, the two interaction constants being roughly equal.

The decay of ^{228}MsTh$_2$ was reported by Dr. C. G. Campbell (Edinburgh). A double β-spectrometer was used and the partial spectra separated; six such have been found with end-points and intensities as follows:

Energy limit	2·18	1·85	1·72	1·15	0·66	0·46
Intensity (per cent)	10	9	7	53	8	13

Photodisintegration

J. R. Atkinson (Glasgow) reviewed the field photodisintegration in stimulating fashion. divided the reactions into three categories—(i) γ, γ, *n*; (ii) γ, *p*, *n*; γ, *d*; γ, α; (iii) γ, stars—and discussed for each the excitation curve, angu distribution, experimental methods and theoreti treatment. For (i) and (ii) the curves are ab 5 MeV. wide for a large range of values of ator number, but for (iii) there is resonance at discr γ-ray energies. There appear to be anomalies in form of the excitation curve and the angular d tribution for the processes (γ, *pn*) and (γ, *d*). T stars appeared to be anisotropic. The theoreti models (Levinger/Bethe, Weisskopf, Goldhab Teller) leave much to be desired. The discuss of the work of the Glasgow team (with expansi chambers) centred on helium as target, and t criterion of selection was the close agreement of t quantum energy E_γ of the incident radiation determined by two methods. Current work with t smaller Glasgow synchrotron on the disintegrati of nitrogen promises to be fruitful.

F. K. Goward described the very interesting wc which he and J. J. Wilkins are prosecuting at t Atomic Energy Research Establishment, Harwell, which the photo-emulsion technique has be exploited fully in the study of stars; more recent the gridded ion chamber has helped to improve t energy resolution of levels. The technique w admirably illustrated with slides of a variety star-processes. For the reactions:

$$^{12}\text{C} + \gamma \rightarrow 3\alpha - 7{\cdot}3 \text{ MeV.}$$

$$^{16}\text{O} + \gamma \rightarrow 4\alpha - 14{\cdot}4 \text{ MeV.}$$

about 2,000 and 600 stars, respectively, have be measured. The quantum energy was deduced adding the binding energy to the measured tot energy release. The cross-section curve for (1) sho a doubly peaked curve, suggesting competition wi (γ, *n*) and (γ, *p*) reactions and implying the formati of a compound nucleus. A series of narrowly spac resonances (~ 1 MeV. apart) is probably superpos on a continuum, giving levels of carbon-12. Likewis it seems that the levels of oxygen-16 are excited, a levels of intermediate nuclei—for example, ber lium-8—could be observed.

A paper on photodisintegration, by Mr. J. M. Re (Glasgow), dealing with the application of countr techniques, was given at a special sectional meeti in the afternoon.

The S-Matrix

J. Hamilton (Cambridge) discussed the work C. A. Hurst on the convergence of the renormaliz *S*-matrix perturbation theory expansion (after Dyso regarded as a power series in the coupling consta The theory treated was a scalar meson field coup scalarly to itself—the so-called 'φ^3' theory.

Estimation of the number of irreducible graphs order *n* contributing to a chosen physical proce gives $(n/k)!$ for large *n*, where *k* is a small integ probably 2. The sign and magnitude of the co tributions from these graphs are not easy to find, a Hurst limited his discussion to processes which not relate to real particles, thus avoiding difficulti possibly arising from the creation of new particle It is thought that the restriction can be thrown o by analytical continuation in the energy plane. For rticular process the series of contributions from the educible graphs diverges in an oscillatory manner th great rapidity. When the coupling constant is iall, say 1/137, successive terms decrease rapidly at st, but ultimately the enormous number of graphs comes the predominant factor. In pseudoscalar meson theory the coupling constant may be in the nge 4–40, and at no stage does the series even pear to converge.

During the discussion, Prof. Peierls pointed out at a weakness of the work is the lack of any timate of the finite contributions from the self-ergy and vertex parts occurring in the graphs.

The work of B. F. X. Touschek and of Dr. W. K. irton on field equations and commutation rules is then described by the latter. Dr. Burton re-rred to a recent paper by J. Schwinger[1] which ves an account of a comprehensive scheme for e quantum mechanics of localizable fields based an operator Lagrangian. The theory makes no peal to the correspondence principle or an under-ing classical theory, and all the results are derived om a single fundamental principle analogous to amilton's principle in classical theory. This theory s been shown by Burton[2] to lead to a particularly nple derivation of the S-matrix series in terms of e interaction Lagrangian. Schwinger describes how e commutation relations are to be obtained from e fundamental postulate; and, by studying camples from particle mechanics, Burton and uschek found that the Schwinger method gives a ique prescription for the determination of the mmutation rules for systems free from anholonomic nstraints. If such constraints are present, the ethod may—in special cases—no longer apply as it ands. Equations of the Dirac type belong to this tegory, since the number of degrees of freedom is st half the number of co-ordinates appearing in e Lagrangian.

The final lecture, by Dr. J. S. R. Chisholm lasgow), dealt with the calculation of higher order matrix elements. Dr. Chisholm demonstrated plicitly automatic procedures for carrying out the lculations according to a prearranged programme. evious efforts in this field appear as special cases the general method which he detailed. Dr. iisholm brought out clearly the principles described length in his published work[3]. S. C. CURRAN

ROGRESS OF CANCER RESEARCH

THE reviewer of a production like the Annual Report of the British Empire Cancer Campaign*, hich covers a wide field of research, will naturally nd to limit his choice of investigations for descrip-on to those with which he feels at home, or which em to him to be especially interesting, original or omising. The subjective element in selection is avoidable and, in fact, will become more pro-unced as cancer research extends, since the range studies as a whole is beyond the scope of any one viewer.

Carr, in experiments on the virus of Rous sarcoma, is found that it is recoverable from the leg of a chick when the muscle is extracted a few hours after injection; after 6 hr. it can no longer be detected in any quantity, but at 66 hr. it can again be separated in amount greater than was injected. It is believed that the infective virus disintegrates into smaller components inside the cell, that these multiply and recombine to give the infective virus. "All these considerations lead to the suggestion that infective virus is present in the cell for only a very short proportion of the mitotic cycle. It therefore seems probable that the malignant condition is caused by some earlier stage of the virus multiplication cycle, and this leads to the possibility that a tumour may sometimes result from a non-infective virus."

Investigations at the Chester Beatty Institute on chromosome abnormalities induced in *Drosophila* by chemical mutagens (nitrogen mustards, diepoxides, ethyleneimines, dimesyloxyalkanes) have shown that these changes are observed as partial deficiencies. This fact has been used in support of a theory of malignancy, the outline of which can be sketched in as follows: (1) Many carcinogens are also potent inducers of mutations in *Drosophila*. (2) There must therefore be some fundamental relation between carcinogenesis and mutation (hence the somatic mutation theory of cancer). (3) Mutagens acting on *Drosophila* induce chromosomal abnormalities, namely, deficiencies and minute deletions. (4) It is possible, therefore, that cancerous transformation also is an expression of a chromosomal deficiency, that is, an interference with the reproduction of the gene pattern. (5) Hence the cancer cell is a normal cell which has irretrievably lost something—clearly it has lost its growth-controlling mechanism. (6) The specific hormones control the growth of their target organs and xanthopterin brings about renal hypertrophy; therefore an obvious aim of cancer research must be to find a chemical compound or an enzyme which can replace the lost growth-controlling material of the malignant cell.

There exist some different types of chromosomal aberrations which are not permanent features of tumour tissue. In an account of the work of Koller and associates, it is stated: "From continued study of cytological abnormalities frequently observed in the cells of tumours induced by the aromatic nitrogen mustards it is clear that these are of 2 classes, those which gradually disappear in the course of serial transplantation, and those which continue to be transmitted to the descendant transplant generations, apparently indefinitely. Even these permanent abnormalities are, however, still regarded only as associated changes, and not in themselves the cause of the malignant alteration, which can clearly occur in their absence. They are nevertheless of great interest as suggesting a likely site of action of these carcinogens, and it is probable that the malignant transformation itself involves a much less tangible or even 'invisible' effect on the chromosome or gene".

Ludford, who has been studying variations in size and structure of the malignant cells of transplantable tumours in inbred strains of mice, says: "On the basis of these observations it seems justifiable to conclude that cellular polymorphism correlated with variations in chromosome numbers and aberrations of the process of mitosis are not specific features of malignancy but occur, although to a lesser extent, in normal tissues. This suggests the probability that after cells have become differentiated the full chromosome complement is no longer essential for their continued life and functional activity".

---

* British Empire Cancer Campaign 29th Report (1951) Edited by Heneage Ogilvie (11 Grosvenor Crescent, London, S.W.1)

Cancer of the bladder in dye and rubber workers, and skin cancer due to mineral oils in the engineering industry, have been the subject of investigation by Case and by Woodhouse and Hieger. Case, in a statistical examination of bladder cancer, finds that the great increase of this disease between 1901 and 1950 cannot be entirely attributed to an ageing population, nor to improvements in diagnostic method. The occupational study of the rubber industry shows that a hazard is located in the mixing, extruding and vulcanizing sections of the industry, and that the risk was introduced between 1915 and 1930. This date would be compatible with the time when carbon black, some organic accelerators and anti-oxidants first began to be used on a large scale.

The biological testing of fractions of petroleum oils from different sources has as its objects the identification of the active agent in the oils and the development of a technique for assessing the industrial risk attached to the use of any one particular oil. Fractions of petroleum from oil-fields in the Middle East, Venezuela and the United States were prepared by distillation under conditions in which cracking was avoided in order to preserve the composition of the oil as nearly as possible in its original state. These fractions when tested by an elaborately designed series of experiments on mouse and rabbit skin showed pronounced differences of activity; they were much more carcinogenic for rabbit skin than for mouse skin—a further example of the unpredictable differences of susceptibility of different tissues and species to carcinogens.

Doll has conducted an inquiry into factors which may affect liability to cancer of the cervix uteri. It has been shown by a large volume of data that Jewish women have a lower incidence than Gentile women and that child-bearing is conducive to this form of cancer. Gagnon has now produced some unique evidence on this question. In the medical records of a population of nuns (annual average 3,280) in Quebec for the past twenty years, no case of cancer of the cervix was found. Inquiry is being made as to whether a similar investigation could be made in any other country (for example, Bavaria).

Sir Ernest Kennaway and collaborators have carried out an intensive examination of lung cancer, particularly from statistical material and by a study of carcinogens in the atmosphere and in tobacco smoke. Although it is now highly probable that cigarette smoking is an important factor in the very rapid increase in lung cancer in the past few decades, many other problems of lung cancer remain at present unexplained. For example, cancer of the larynx has shown no equivalent increase during this time. In Norway and in Mexico, cancer of the lung is about as frequent in men as in women; in England it is much more common in men; deaths attributed to cancer of the lung in both sexes and to cancer of the larynx in males are higher in the more urban districts, while in women the relation is reversed. The role of the geographical factor in differences of incidence of cancer presents some attractive problems. "The peculiar position of Wales in relation to cancer was first observed by Stocks (1930), who discovered the high incidence of cancer of the stomach in the north-western counties of Wales."

Gwyn and Salaman, in experiments on co-carcinogenesis, have found that if the skin of a mouse is given a single painting with 9 : 10-dimethyl-1 : 2-benzanthracene, followed after an interval of six weeks by treatment with co-carcinogen (croton oil in paraffin oil), the rate of appearance and yield tumours suggests: (1) that there is a critical size f tumours produced by this method which is rath less than that of the smallest visible; tumou smaller than this do not continue to grow—in fa regress—if co-carcinogenic treatment is stoppe (2) the change produced by croton oil in mouse sk previously painted with a carcinogen is a gradu one; it is reversible during the greater part of i course, but becomes irreversible and independent progressive not long before the appearance of visible tumour.

At Leeds, Dmochowski and co-workers have co tinued their researches on the Bittner milk fact Electron microscope photographs show that in hum milk, and in extracts of human breast tumou especially from pregnant women, there exist particl of a size approximately the same as the Bittn agent. The virus is not antigenic in mice, and t antibodies elicited in mice react with extracts mouse tumours whether or not they contain t agent as well as with different normal mouse tissue No evidence could be found of a common antigen human and mouse tumour extracts. Electrophoret estimations show that the infective dose of the mi agent is extraordinarily low, namely, 3 × 10^{-7} μgr of nitrogen.

Dmochowski finds that after eighty-six successi transplantations of the mammary tumour, the mi factor can no longer be detected, although there is histological difference between the tumour at eighty-sixth and forty-second passage. Apparent the presence of the milk factor is not a permane feature of this transplantable tumour, and the ce can continue to multiply even when the agent cann be detected by the technique employed. A simil disappearance of the virus from the transplantab Shope rabbit carcinoma has been described b workers in the United States. Dmochowski refe also to experiments demonstrating the appearance the milk factor *de novo*, as reported in studies b Bittner.

Bonser and Jull have used a new method of testi carcinogens on the bladder by introducing the com pound as a suspension in a paraffin wax pellet direct into the dome of the bladder of the mouse. Epitheli changes starting with hyperplasia and squamo metaplasia, and going on to benign and maligna hyperplasia, resulted from the introduction into t bladder of 20-methylcholanthrene, 2-amino-naphtho and 3 : 4 : 5 : 6-dibenzcarbazole. Claysen reports th a relationship exists between species susceptibility the carcinogenic action of 2-naphthylamine and t proportion of this compound which is excreted 2-aminol-1 naphthol conjugates. Moreover, sin 2-amino-1-naphthol is also carcinogenic when inject subcutaneously, the suggestion is put forward that carcinogenesis by 2-naphthylamine the amine h first to be converted to the naphthol.

At the Sheffield centre, strenuous efforts have be made to induce stomach cancer in rabbits, rats an mice by injecting rapidly-acting carcinogens in stomach fistulæ, by feeding hot food at 55° C., b administration of 2-acetyl-aminofluorene or methy cholanthrene with croton oil by mouth, by exhausti of the mucosal secretion with dodecyl sulphate (with 50 per cent ethanol followed by 9 : 10-dimethy 1 : 2-benzanthracene in the drinking water. Th results were negative. "All the available evidenc still suggests that the stomach is refractory t chemical carcinogenesis because of its powerful mucou rner. Perhaps the main value of all this work is at it suggests that the inducing agent in stomach ncer is not an extrinsic chemical carcinogen."

Pybus and Miller, at Newcastle, have carried out periments somewhat on the lines of Strong's ethod, namely, the injection of mice with methyl-olanthrene for a number of generations to see if bsequent generations will contain mutations served as spontaneous neoplasms without the cessity of applying carcinogens.

Lasnitzki at Cambridge has confirmed Craigie's port that mouse sarcoma 37 consists of at least two pes of cells, the more active variety (round cells fractile in phase contrast) being convertible *in vivo* nd *in vitro* into the more differentiated spindle cells.

Peacock has reported that hybrid mice from *CBA* rain (virus-free) mothers and C_3H (virus-bearing) thers can acquire the virus if the father remains in e breeding box during pregnancy and the puer-rium. If the *CBA* mother is transferred to a sterile reeding box early in pregnancy and remains gregated until the litter is weaned, the female ybrids show no greater incidence of mammary ncer than pure line *CBA* females.

Peacock has been more successful than the Sheffield orkers in inducing stomach tumours in mice ; he sed feeding with carcinogens and with cottonseed l heated to 350° for some hours. In an experiment which the oil was fed for 300 days in a series of ice of which 230 lived more than 400 days, fifteen ses of papilloma and six of squamous carcinoma or denocanthoma of the forestomach and adjacent landular stomach and three cases of adenosis of the ylorus were found. "Thus it seems probable that e 21 cases of tumour of the forestomach among 30 mice fed with heated cottonseed oil were directly lated to this treatment. Though a 10 per cent yield small compared with many experimental results, it at least as high as the incidence of cancer of the omach in the human subject." However, the omach tumours evoked in the mouse are rather ifferent from human gastric cancer, and Peacock ggests that this difference is due to the occurrence f gastritis, pernicious anæmia and achlorhydria, hich is common in man but rare in animals.

The fundamental problems of dosimetry are still ceiving a large amount of attention in practically ery centre concerned with treatment by any form radiation. Methods of measurement vary from the roportion of survivals of the broad bean root to the duction of ceric sulphate. The use of photographic uclear research emulsion for fast-neutron dosimetry also being compared with the more usual method f using an ionization chamber with walls of a gelatin ixture. Depth-dose measurements vary from those ade on a 30-MeV. beam in a water phantom, to eta-rays using a stack of films as phantom. The rotection of workers in these fields is also being ontinually studied. In a number of departments a lm badge service is provided, and one report dis-usses the method of determining the energy of attered rays by means of secondary electronic mission from metal foils. Reports from two centres sing a 30-MeV. synchrotron indicate that while eatment is tedious owing to the low output of 10 r./min. at 1 metre, yet useful information is eing gleaned about the distribution of the dose in ssue. The few patients who have been treated have own encouraging results.

Numerous reports indicate the ever-increasing use radioactive isotopes as a tool for research as well as for diagnosis and therapy. Considerable strides have been made in the design and operation of scintillation counters, and reports from a number of centres indicate that the increased sensitivity of this means of detecting radiation should lend itself to a much more efficient study of radioactive material in the body. A 4π scintillation counter for the absolute standardization of radioactive isotopes is also reported. The importance of absolute standardization, particularly of radioactive isotopes in frequent use, has been realized, and work is going on in several centres to attempt to reach agreement on this point. There is an increasing demand for discrete sources of radiations, and work is reported on surface applicators, using the gamma radiations from gold-198, which is spread over a 'Perspex' or polythene mould in the form of gold foil of varying thickness, and the entire unit then irradiated at the Atomic Energy Research Establishment. Cobalt-60 is now used as a central source in the intracavitary treatment of carcinoma of the bladder and also in the treatment of carcinoma of the cervix. Superficial beta-ray applicators using phosphorus-32 (as red phosphorus) incorporated into plastics are also giving encouraging early results. The installation of two cobalt-60 beam-therapy units using up to 1,400 Curies of cobalt-60 is reported from Canada (see also *Nature*, 168, 1035 ; 1951).

The clinical and pathological reports consist chiefly of the continuation of orthodox analyses of malignancy at various sites with correlations including stage, histology and response to treatment. The findings confirm the value of histological grading in assessing prognosis. Similar investigations are being carried out independently at a number of centres in Great Britain, but there is little evidence of any co-operative planning. The most detailed survey reported is on seventy-four cases of nephroblastoma from the Hospital for Sick Children.

At the Chester Beatty Institute it is found that 1 : 4-dimethanesulphonoxybutane given in long courses of small doses has proved capable of producing remissions of therapeutic value in myeloid leukæmia. At both the Westminster and the Christie Hospitals it has been found that the nitrogen mustards are useful in the treatment of advanced Hodgkin's disease.

Glucksmann and his colleagues are studying the mechanism of lymph-node involvement and the reaction of the node to the presence of tumour in cancer of the cervix. They have also accumulated impressive results on the value of the cytological analysis of serial biopsies in the assessment of the radiocurability of cancer.

Cuthbert Dukes has confirmed the frequent development of cancer of the large bowel in long-standing cases of ulcerative colitis. He and his colleagues have found that precautions recently adopted to prevent implantation of cancer cells during the operation of restorative resection for cancer of the rectosigmoid have indeed prevented the recurrences at the suture line which were met with formerly.

Price, at Bristol, in an analysis of thirty-six cases of osteogenic sarcoma, found the mitotic ratio (the number of resulting nuclei to one in mitosis) to be the most reliable index of malignancy. A mean mitotic ratio of 238 to 1 was obtained for the whole series, based upon an examination of at least 2,500 nuclei for each count. The tumours were divided into three grades of malignancy on the basis of the mitotic ratio. These showed good correlation with the time of survival of the patients in months from the date of the presenting symptom. The conclusions are most promising, but it would appear that the number of mitotic cells counted, especially in the 'low-grade' malignancies, must have been extremely small. His published article on this work does not give the actual number of mitotic cells counted and therefore does not dispel statistical doubts about the method as it stands.

PHYSICAL CHEMISTRY OF PROTEINS

A GENERAL discussion on "The Physical Chemistry of Proteins" was held by the Faraday Society in the Department of Zoology, University of Cambridge, during August 6–8. During the meeting, introduced by Dr. J. T. Edsall of Harvard University delivering the sixth Spiers Memorial Lecture, some twenty-five papers, a large proportion by foreign authors, were presented.

The programme was divided into five sections arranged in order of increasing complexity: (1) experimental techniques, (2) low molecular weight proteins, (3) high molecular weight systems, (4) protein interactions, (5) conjugated proteins. An audience of 350–400, containing many guests from abroad, attended.

Dr. Edsall, a Fulbright Fellow of the University of Cambridge, began by reviewing the fundamental changes in our ideas on proteins since the middle twenties, when little quantitative information was available. Subsequent years saw the development of the ultracentrifuge and other physical methods by which information on the size and shape of many proteins has been obtained. Among recent developments, Dr. Edsall mentioned particularly the work of Sanger and co-workers, which has provided very complete information on the sequence of amino-acids in insulin, and the structural suggestions of Pauling, Corey and co-workers. Illustrating the state of our knowledge of the physical chemistry of proteins, Dr. Edsall dealt in detail with two important proteins —fibrinogen and serum albumin. There was general agreement that fibrinogen is an asymmetric molecule of molecular weight c. 400,000, but many more detailed questions and the mechanism of blood clotting require further study.

Serum albumin is one of the most-studied proteins. The molecular weight was thought to be c. 69,000 until very recently, when new experimental work has indicated that a somewhat lower value may be correct. As to the shape of the molecule, the greater part of the data is in accord with an ellipsoid of rotation of low axial ratio; details remain to be settled. While the molecule is supposed to be relatively rigid in solution, it is possible that some flexibility of the surface exists; such a property would go far towards explaining the ability of the molecule to combine with a large variety of organic and inorganic materials. Dr. Edsall considered in detail the binding of zinc and mercury atoms.

In section 1, only the more recent advances in experimental techniques were considered. In a paper by A. Tiselius, zone electrophoresis in filter paper and other media was reviewed. Since separate bands are thus produced, the method has distinct advantages over boundary electrophoresis as a preparative tool. It can readily be operated on a micro scal at low concentrations and for a variety of materia of low molecular weight as well as macromolecule On the other hand, electro-osmosis and adsorptio may hamper quantitative work, and special measur are necessary if such effects are to be avoided. (Weber presented a paper on the use of measuremen of the polarization of fluorescence in investigati proteins in solution. Results on several protei preparations were quoted, among which those c bovine serum albumin, indicating reversible dissociation at low salt concentration and acid pH's, were especial interest. Variation of the protein concentration causes no apparent effect on the dissociatio Confirmation of these results was reported fro osmotic pressure and sedimentation-diffusion studie Several workers, however, were doubtful about th interpretation, attributing the apparent dissociatio to effects of the high positive charge of the molecu under the conditions of the experiments. A fin paper in this section, by J. S. Falconer, D. J. Jende and D. B. Taylor, dealt with the application of solubility measurements to the study of complex protei solutions and to the isolation of individual protein In illustration, the fractionation of rat liver wa considered.

The section on low molecular weight proteins bega with a paper by P. Doty and G. E. Myers dealing wit the thermodynamics of the association of insuli Light-scattering measurements at acid pH's an varying salt concentration were used to evaluat the constants governing the equilibria betwee monomer, dimer and trimer over the range 20°–40° C From discussion of the molecular weight of the insuli monomer, it would appear that the bulk of the kineti data now supports the value 12,000. In a paper b H. Neurath and co-workers, the kinetic behaviou of trypsin and related molecules was considere When trypsin is examined under conditions favourable to enzymatic activity, the sedimentation constant, varying with the age and pH of the protei solution, corresponds with autolysis of the protein On the other hand, when the enzyme is stable an inactive, no such anomalies are observed. Trypsinogen and the diisopropylfluorophosphate derivativ similarly show normal behaviour. A molecular weigh of 24,000 was reported for the inactive proteins G. E. Perlmann presented an electrophoreti study of enzymatically modified ovalbumin an casein. The reactions considered were: (1) th ovalbumin—plakalbumin transformation in whic carboxyl groups are liberated, and (2) the dephosphorylation of ovalbumin, plakalbumin and casein In each case, characteristic changes in electrophoreti mobilities and patterns were produced; electrophoresis is thus a useful tool in following enzyme change involving charged groups. E. Barbu and M. Jol dealt with the transformation of certain globular int fibrous proteins by moderate heating, salt effect, (high pressure. Several physical methods we utilized, and the authors suggested that end-to-en aggregation rather than unfolding of the molecule is responsible for the fibrous products obtained Denaturation was treated in the light of the result obtained. In the following discussion, several worker directed attention to denaturation reactions whic would be difficult to explain by end-to-end aggregation and for which chain unfolding is the more likel explanation.

In section 3, the first paper, by P. Johnso and W. E. F. Naismith, reported experimental result reversible association-dissociation reactions curring in the conarachin fraction of the groundnut obulins. Higher ionic strengths and pH favour the ssociated form, whereas low ionic strength and pH's ar the isoelectric point give large proportions of sociation products. Light scattering, which shows e rapid establishment of equilibrium, confirms dimentation results; but electrophoresis gives no dication of the reactions occurring. In the dis- ssion, attention was directed to the possible effects rapid equilibria on the behaviour of moving boun- ries. In a paper by S. Shulman, the effects of rtain ions and neutral molecules on the conversion fibrinogen to fibrin were considered. Many mpounds, under similar conditions, are found to lay clotting by at least twenty-four hours (inhibi- on), though this action is reversible. Others cause uch less delay in clotting (retardation). Correlation tween the structures of the different compounds d their inhibitory action was attempted. Miss M. Petri and A. J. Staverman dealt with the ectrochemical properties of lupin seed protein. he isolation and chemical analysis of the protein ere described; membranes prepared from it were vestigated with respect to their electrochemical haviour. The effect of various chemical modifica- ons has similarly been studied. Considerable dis- ssion of the nature of the reactions involved llowed.

The remaining papers in section 3 discussed uscle and its proteins. G. Hamoir described an ectrophoretic study of the muscle structural proteins -myosin, actin, actomyosin and tropomyosin— bbit and carp muscles mainly being used. Dr. amoir considers that his results demonstrate the frequent occurrence of interaction between the fferent components; but in the discussion following, appeared that other workers do not agree that ectrophoretic diagrams exclude such effects. In art 1 of a paper on energetics and molecular mechan- ms in muscle action, M. Morales and J. Botts mmarized experimental data on thermoelastic operties of myosin threads, and on light scattering d kinetic measurements on actomyosin–adenosine iphosphate systems. This was interpreted in terms a theory which assumes that the elastic particles ntract by virtue of the increased entropy resulting it extend by reason of electrostatic forces. In part by T. L. Hill, several simplified though possible odels of the basic elastic element were considered, d the detailed properties were calculated by atistical thermodynamical treatments. T.-C. Tsao d K. Bailey presented a paper on aspects of lymerization of proteins of the muscle fibril— opomyosin, myosin and actin. Tropomyosin and tin react very differently to the addition of elec- olyte. Myosin, of greater constancy in its mole- lar weight, is thought by them to contain two types sub-unit, a cyclic and an open-chain unit, each quiring special conditions for isolation. A detailed scussion of these papers followed.

Prof. L. Pauling introduced the proceedings of ction 4 with a speculative discourse on the different pes of association phenomena which are likely to llow mild modification of a protein system. For tensive association to occur, a single molecule must provided with at least two active points on its rface; head to tail aggregation would then produce helix the character of which would be determined the relative positions of the reactive points on the otein surface. Different types of packing of such helices, stabilized by appropriate forces, as well as their interpenetration in various ways, were further possibilities. This approach, though speculative (and termed 'snip and fiddle' by one speaker) may well be basic to many aggregation phenomena involving proteins. A paper by E. J. Cohn and co-workers dealt with the interaction of plasma proteins at physiological pH with metals, alkaline earths, carbohydrates, and formed elements of the blood. Much of the information presented is now being utilized in the Harvard laboratory in new fractionation procedures for the plasma proteins. I. M. Klotz and J. Ayers reviewed earlier work on the binding by serum albumin of organic anions and cations and described new work with related neutral molecules. The results indicate that the protein undergoes configurational changes with change of pH or electrical charge. Low hydroxy-amino-acid content was discussed as a cause of the binding ability of serum albumin, and, in confirmation, the binding of α- and β-casein is found to be appreciable though lower than that of serum albumin. B. S. Harrap and J. H. Schulman presented work on the influence of salt on the size and shape of a complex between sodium dodecyl sulphate and bovine serum albumin. Using viscosity and light-scattering measurements in salt solution, definite complexes of low asymmetry were indicated; in absence of salt no definite complexes occurred, though uncoiling of the molecules was indicated. E. Gorter and L. Nanninga reported a detailed study by physical and other methods of the interaction of several proteins with heparin, suramin and chondroitin sulphuric acid. The interaction occurs between the SO_3^- groups of the latter compounds with positive groups on the protein, and is therefore very dependent on pH. The action of heparin as an anticoagulant was discussed in the light of these results. M. Fleming and D. O. Jordan presented results of an electrophoretic study of calf thymus deoxypentose nucleoprotein and of tobacco mosaic virus. Under certain conditions, the nucleoprotein dissociates into two fractions, and it is postulated that one fraction is protein, leaving a conjugate richer in nucleic acid. The final paper in this section, by R. J. Goldberg and J. W. Williams, was concerned with the antigen–antibody reaction. Adapting the statistical mechanical treatment of three-dimensional polymer condensation to the combination between antigen and antibody, predictions of the position of inhibition zones and antibody–antigen ratios in precipitates have been compared with experiment.

Section 5 began with a review of conjugated proteins by Prof. M. Stacey. Concentrating on complexes of proteins with nucleic acid and carbohydrates, Prof. Stacey mentioned particularly virus and bacterial nucleoproteins, the transforming principle of pneumococcus, mucopolysaccharide blood-group factors and certain recently studied mucoproteins. F. B. Seibert dealt particularly with tuberculin proteins, prepared from unheated tuberculin filtrates as well as live bacillary bodies. A study of their amino-acid content, electrophoretic mobilities, ultraviolet absorption, nucleic acid and carbohydrate content was considered in relation to their biological potencies. E. J. Ambrose and J. A. V. Butler presented data on the swelling of nucleoprotein films in the presence of various salts. The concentration of salts required to prevent swelling is of the same order as that required to precipitate the nucleoprotein from solution. Infra-red absorption and double refraction of partially orientated films is compatible with parallel arrangement of β-polypeptide chains in the direction of stretching, the planes of the purine and pyrimidine rings lying perpendicular to this direction. Other structures are, however, possible. K. Meyer presented evidence for the existence of protein complexes of hyaluronic acid and chondroitin sulphates from hyaline cartilage and connective tissue. Reversibly formed polar complexes with the protein are suggested except in the case of chondroitin sulphate from connective tissue, which is stably linked to protein. A. G. Ogston and J. E. Stanier have isolated the hyaluronic acid complex from synovial fluid by ultrafiltration, since they believe that precipitation affects the physical properties. Such preparations contain 27 per cent protein, the removal of which caused a change in properties. Physical methods have indicated that the complex exists as a random coil of nearly spherical shape and large hydration. Its biological function was discussed.

OBITUARY

Sir Richard Gregory, Bart., F.R.S.

"My particular mission has been to make men of science conscious of their power and influence in shaping civilized life." So wrote Sir Richard Gregory in his message of farewell published in *Nature* of January 7, 1939, when he resigned from the editorial chair which he had occupied with such distinction for so many years. Throughout his long life, which came to a close on September 15, his interest in science for its own sake, and equally for the appreciation by others of its value and significance for humanity, was a driving force which brooked no obstacle, and happily that interest was sustained to the end.

Richard Arman Gregory was born in Bristol on January 29, 1864. His first post was as laboratory assistant at Clifton College. From there he passed on to the Royal College of Science, London, where he met several of the men who were to exert such an influence on him, as he on them, in later years—H. G. Wells, T. H. (later Sir Thomas) Holland, and especially Sir Norman Lockyer. He became research assistant to Sir Norman, and from that period arose a lasting love for astronomy and astrophysics. At this time he began to contribute occasional notes to *Nature*, of which Sir Norman had been editor since its foundation in 1869, and in 1893 he was appointed sub-editor of the journal. This marked a turning point in his career. Until then, his first interest had been astronomy, with the general feeling for science as a whole and its applications to human welfare. From then on, this second interest grew in intensity, and as the years went by and Lockyer left *Nature* more in the hands of his young colleague, it became his guiding influence. In articles, in lectures and addresses, he was never tired of developing and enlarging this theme.

While Lockyer had established the general lines on which *Nature* was conducted, and built up its reputation, Gregory did not hesitate to introduce innovations. Thus to make the journal a living force in the nation and the whole world of science, he felt it was necessary to publish more than occasional leading articles ; and in due course—but not without a certain amount of opposition—he got his way, a the leading article expressing a point of view matters scientific or their significance became regular feature of the journal. For some fifteen sixteen years of this period, he virtually conduct the journal himself, carrying out administrat duties as well as the normal tasks of sub-edit During his annual holidays, he remained in touch post. In 1919, Lockyer retired, and Gregory to over the full responsibility which he had already be exercising for some years. His work continued, f he was a true working editor, marking manuscrip for the printer and seeing the journal through t press week by week with all the attention to dete such work demands.

There was never an editorial committee ; neith was there even a special panel of reviewers. The ent scientific world, both at home and abroad, has alwa been *Nature's* willing advisers and critics. Thu through this valuable freedom from committee contr and especially through the integrity and fearlessne of its editor, was Sir Richard able to contribute ve largely towards making the journal what it is— journal of science, published for men of scienc written by men of science. He accepted the sayin that 'a good editor wears out the soles of his sho before the seat of his pants' ; and was always read to consider fresh views even if they conflicted wit those accepted.

In spite of the heavy load of work which h assumed in this way, this did not by any mean exhaust Gregory's seemingly unlimited store c energy. A short period of teaching in the Dockyar School at Portsmouth earlier on, coupled with hi own personal experiences, persuaded him that ther was a dearth of good school science text-book Starting with astronomy and what used to be terme 'physiography', he began writing text-books whic quickly made their mark for their accuracy an practical approach, and their appreciation of students difficulties. Alone and in association with others notably the late H. E. Hadley and A. T. Simmons he wrote and edited a number of such books, man of which are still in use both in Great Britain an overseas after passing through several editions. B his sustained interest in scientific developments h was able to keep these books in line with scientifi progress, even within the past two years.

This interest in education also showed itself in hi activities in the British Association. He was one o the leaders in the formation of Section L (Education of the Association, and for its first ten years serve as one of its secretaries or its recorder. In 1922 h was president of the Section. In 1899 he helped t found the *School World*, which was later incorporate in the *Journal of Education*, and he was joint edito until 1938.

Almost as a by-product of his work for *Natur* was his book "Discovery : or the Spirit and Service o Science" published in 1916, in which he outlined i his characteristically clear and simple style som leading scientific discoveries, using them to illuminat his perennial theme, the worth of science.

From an early date, Gregory had been in consider able demand as a lecturer. On the platform h divided his attention between astronomy and th social implications of science ; and as the years went by he identified himself more and more with the latter topic. Here may be mentioned his work for the British Science Guild. This body, formed to promote the appreciation and application of scientific ethods in public affairs (and incorporated in 1936 to the British Association), owed much to his tiring activities. At the close of the First World ar, the Guild promoted a very successful British ientific Products Exhibition, as a result of which egory was awarded the honour of knighthood.

A list of scientific societies which honoured him electing him president ranges from the Science asters' Association (1927), through the Royal eteorological Society (1928 and 1929), to the Conrence of Educational Associations (1931). Finally, st before the ill-fated Dundee meeting of the itish Association was abandoned in 1939, he was ected president for the ensuing year and held office roughout the Second World War. During this fficult period he was ever mindful of the Associaon's affairs and even succeeded in organizing limited eetings at Reading, Manchester and London. Each dy with which he became associated from time to ne had his enthusiastic attention and support, and ofited from his wide knowledge of men and affairs.

In 1931 he was created a baronet. Honorary grees were conferred on him by the Universities of eds, Bristol and St. Andrews; but the scientific nour which he probably prized most was his ection as a Fellow of the Royal Society under the le which empowers the Council to recommend ection "for conspicuous service to the cause of ience". This was in 1933, when he was recovering om a long illness which had kept him—albeit very willingly—from the editorial chair for two to three onths. This indeed was the first time since his pointment to *Nature* that he had been compelled lay aside his duties and self-imposed tasks for so ng a period. Yet even during that time he arranged see one or the other of his assistant editors to scuss the journal.

It is probably no exaggeration to say that, by rrespondence and personal contact, Sir Richard d a wider acquaintance with scientific men throught the world than any other individual during the st two or three decades of this century. These iendships, many of which were warmly confirmed hen visitors from overseas came to Great Britain, ere strengthened and extended by three visits, to uth Africa (with the British Association), to India d to the United States, where he delivered the lihu Root Lecture in the Carnegie Institution of ashington in 1938.

Since Sir Richard was within two or three weeks his seventy-fifth birthday when he retired from e editorship of *Nature* and took up permanent sidence in the charming old Manor House at iddleton-on-Sea, it might have been thought that would be content to rest from his labours. But has been said, he sealed his long connexion with e British Association—he had attended practically ery meeting for more than fifty years—by accept g the presidency and, as it transpired that this as for a long period (1940–46), he still worked r it while he was supposed to be living in retireent. This was not his only activity. He maintained rrespondence with his many friends, and any ppeal which seemed to offer a chance of promoting e cause of science or its appreciation was sure of is sympathy and advice. For example, during this eriod he was largely instrumental in securing the ansfer of the Norman Lockyer Observatory at Sidouth, of which he had been chairman of the governg body for many years, to the University College f the South-West, Exeter, thus ensuring its future.

One concluding word: we have tried to give an impression of the intense activity which filled Sir Richard Gregory's life. But he was no mere automaton, for he showed a very human enjoyment of his manifold interests, and we who worked with him always found him a very sympathetic, understanding and kindly man.

Sir Richard was twice married. In 1888 he married Kate Florence Dugan (*née* Pearn), who died in 1926 after a long and distressing illness; his son and daughter by this marriage both predeceased him. Secondly, in 1931, he married Dorothy Mary, daughter of the late Dr. William Page, general editor of the "Victoria County History", who survives him. Lady Gregory was his constant companion and helper throughout their married life, and her care and attention were a source of much happiness during his declining years.

THERE are very many of us who held Richard Gregory in close affection—scientists most of us, of all ages, but many with other activities and interests; and we are all feeling very deeply the gap which his going has left in our circle. We could not wish him to linger in his final illness; but, as members of an even much wider community of all who work in science, or are concerned in any way to promote the recognition of its present and future importance in the world, we are feeling sadly bereft of his genial presence, his tireless enthusiasm and his doughty championship. We seem to be looking at the end of a great chapter, with the closing of a long life so completely devoted to science and to all who serve it, during the period in which he watched its amazing development. When we heard his telegram of apology read at Belfast, it was heartening to feel that our gallant old friend still kept so much of his buoyant humour and that the flag of his courage was still flying, in face of the end which he must have known to be near.

A full tribute is being paid elsewhere to his central and most direct service to the progress of science, as the Editor of *Nature*, and to his other work for scientific education at all levels. We who knew him, however, in the intimacy of friendship, are thinking most now of his cheerful, generous, lovable personality, of his memory filled to overflowing with so rich a variety of knowledge and anecdote, of the racy, inconsequent, garrulous flow of his reminiscences. What a life-story he could have written!—from the days of his early, heroic climbing of the educational ladder—there were no escalators then—until, for well over half a century, he made friendly contacts with Britain's scientists, from the greatest to the least, and with many from other countries. Few, indeed, have been so widely known and trusted. Our deepest sympathy, in her bereavement, is with the brave and gentle comrade who brought him such happiness, and cared for him with such loving devotion in his later years.

H. H. DALE

MAY I be allowed among many others to pay my tribute to the work of Sir Richard Gregory in raising science to its present position in our national life, and particularly in insisting on the need for giving it a higher place in our educational system than it had had before. He early recognized the importance of developing agricultural science in Great Britain, even in the days before it was accepted at the universities as suitable for inclusion in their syllabuses, and he always insisted that agricultural education, widely admitted as necessary at least for countrymen, must be based on sound scientific research.

It will not easily be forgotten at Rothamsted how he helped the appeal for funds that had to be made in 1934 when the Lawes family, owners of the estate which included the experimental fields and the laboratories, found they could retain it no longer but must part with it. The fields were then, in the language of the time, 'ripe for development', and builders were already assessing the possibilities for villa residences; no Treasury grants were available for the purchase; the money had all to be raised privately and quickly, and times were hard. Sir Richard gave the appeal whole-hearted support: he and H. G. Wells jointly wrote a letter to *The Times* in which with his accustomed lucidity he expressed his views on agricultural science: "whatever may be said of other branches of science", he wrote, "the results of research in agriculture cannot be used for purposes of destruction but only to give mankind knowledge by which the factors that determine the production of food may be effectively guided and controlled for the comfort of all. No higher motive of research than this can be conceived".

This was no mere passing expression of opinion: it was his consistent attitude to the subject and it inspired his friendly attitude to the workers. Critics had sometimes asserted that they should devote themselves mainly to the solution of specific farm problems; he always supported the Rothamsted view that their proper function was to build up a systematic science which should relate the facts and seek the underlying causes; it would then be possible to make better use of the facts than when they were only imperfectly known and understood. He had the personal link with Rothamsted that his only son Edgar, after retiring early from the Indian Army, joined the staff as guide demonstrator and thus became one of the pioneers in the art of presenting agricultural science to two completely different audiences: the countryman who already knows many of the facts, and the townsman who is often completely ignorant of them but who depends for his daily bread on their proper understanding by the right people. I always hoped that father and son might collaborate in producing a simple book setting forth the material in easily understandable language, but Edgar's untimely death and Sir Richard's many other activities prevented this. But his services to agricultural science, though quiet and unobtrusive, remain in the memories of those who knew him. E. JOHN RUSSELL

SIR RICHARD GREGORY was president or chairman of many societies and congresses, including the Royal Meteorological Society, the Geographical Association, and also the British Science Guild until that was merged, at his instance, with the British Association in 1936. His kindly spirit set store by the social contacts of conferences only less strongly than did his eagerness to further the progress of science. It is therefore probably true to say that his first and last love among the societies to which he belonged was for the British Association. Of this he became an annual member in 1896 and a life member in 1901. There was no more regular attendant at its annual meetings than he, and the last of these at which he was seen was that at Edinburgh in 1951. This his poor health compelled him to leave before its finish, and at the recent meeting in Belfast his telegram of greeting to the Council was welcomed with inevitab regret.

Gregory's early activities in the Association we concerned with the establishment of the Section Educational Science in 1901, and with work o various committees appointed at the instigation that Section. He acted in due course as a secreta and as recorder of the Section. But his first recorde contribution of a paper was not to the education but to the Section of Geography in 1908, when h presented geography as "one of the most valuab subjects in a school curriculum", as providing n only intellectual discipline but also the huma interest of "the most inspiring literature". Th theme recurred incidentally in his finely phrase presidential address to the Education Section in 192

His presidency of the Association came in 194 and was unique in having lasted for six years. Durin the War there were no annual meetings of th Association on the usual scale, but Gregory eager supported the conferences arranged in London b the Association's Division for the Social and Inte national Relations of Science, of which at least on that on "Science and World Order", which broug together not only British speakers but also foreigne of eminence who had found refuge in Britain, attracte attention far outside the meeting-hall, and inde beyond the confines of science itself. Gregory presidential address, too, was given in unique circum stances, the sole public pronouncement at a one-da meeting in 1946 held in the hall of the British Medic Association, since there had not been time to arrang an annual meeting on the full scale immediately aft the end of the War. Whatever disappointme Gregory felt at not presiding over such a meetin was concealed in his readiness to serve the Associatio to the best advantage as judged by those who worke with him, by one of whom this tribute to his memor is gratefully contributed. O. J. R. HOWARTH

MEMORIAL SERVICE

A memorial service for Sir Richard Gregory wi be held in St. Martin-in-the-Fields Church, Londo on Friday, October 3, at 12 noon.

NEWS and VIEWS

Henri Moissan (1852–1907)

BORN in Paris a century ago, on September 2 1852, Henri Moissan was appointed demonstrator a the École de Pharmacie, Paris, at the age of twenty seven. After obtaining his doctorate in scien in 1885, he became professor of toxicology in th following year, and professor of mineral chemist in 1889. In 1900 he was called to the chair of che istry at the Sorbonne. He is best known for havi isolated and liquefied fluorine, for which he receive the La Caze Prize of the Paris Academy of Science in 1887, and for his development of the electr furnace, which made possible the reduction of ve refractory metals. His preparation in 1893 of minu artificial diamonds by extremely rapid cooling of solution of carbon in molten iron created a gre sensation at the time. He also simplified the pro duction of acetylene. Moissan shared the Hofman Medal of the German Chemical Society with Si William Ramsay in 1903 and was awarded the Nobe Prize for Chemistry in 1906. His most importan ooks include "Le Four Electrique" (1897 ; English ranslation, 1904), and "Le Fluor et ses Composés" 900). He died on February 21, 1907.

nter-African Labour Institute

Miss Sheila Ann Ogilvie, at present assistant bour adviser to the Secretary of State for the olonies, has been appointed the first director of the nter-African Labour Institute, with headquarters at amako in the French Sudan. The Institute is to rovide a permanent centre for the collection and istribution of information on labour problems in frica, and is under the auspices of the Commission r Technical Co-operation in Africa, which was set p in 1950 by the Governments of Belgium, France, ortugal, Southern Rhodesia, the Union of South frica and the United Kingdom to promote interational technical co-operation in Africa south of the ahara.

nternational Council for the Exploration of the Sea

Founded in Copenhagen on July 22, 1902, by enmark, Finland, Germany, The Netherlands, orway, Russia, Sweden and the United Kingdom, he International Council for the Exploration of the ea is celebrating its jubilee by a meeting in Copenagen during September 29–October 7. The Council as founded upon the initiative of Sweden, which in 899 held a conference at Stockholm on international nvestigation of the sea ; in 1901 a similar conference ook place at Christiania (Oslo), followed by a meeting t Copenhagen in 1902, at which the Council was ormed, its purpose being to promote practical scienfic investigations of the food fishes, plankton and sea ater, as a basis for international conventions aiming t securing a better output of the fisheries. The first resident was Dr. W. Herwig (Germany), with the ollowing national members of council : Otto Petterson (Sweden), Dr. P. P. C. Hoek (The Netherlands), apt. C. F. Drechsel (Denmark), Prof. Fridtjof Nansen Norway), Dr. Oscar von Grimm (Russia) and Prof. 'Arcy Thompson (United Kingdom). The jubilee eeting will be attended by about two hundred elegates and guests from the member States of the ouncil, and observers and guests from the United tates of America, Australia and Canada. The Interational Council itself consists of two government elegates appointed by each participating State, nd it elects a president, a first vice-president nd three vice-presidents who form the Bureau, hich has always had its central office in the castle f Charlottenlund, Denmark. The present officers re : *President*, Dr. K. A. Andersson (Sweden) ; *irst Vice-President*, Mr. A. T. A. Dobson (United ingdom) ; *Vice-Presidents*, Mr. G. J. Lienesch (The etherlands), Prof. Jean le Gall (France), and Dr. . U. Sverdrup (Norway).

oyal Alfred Observatory, Mauritius : Report for 1950

The annual report for 1950 of the Royal Alfred bservatory, Mauritius (pp. 12 ; Govt. Printer, Port ouis ; 1951 ; 25 cents) deals with the functions of he observatory department, which are meteorological nd magnetic ; the provision of meteorological serices for government departments and all other urposes ; and the organization of meteorological bservations in the Colony of Mauritius and in its ependencies, etc. Pilot balloon observations were made daily at the Observatory, and, when conditions were suitable, additional ascents were made at the islands of St. Brandon and Agalega. A description of tropical cyclones and cyclonic depressions during 1950 is given and also the data on the rainfall, which was 42·36 in.—83 per cent of the normal amount. The organization of returns from rainfall stations has resulted in returns from 157 of these, of which 130 made complete returns in 1950. This shows a marked improvement on 1948 and 1949, in which the returns were fifty-five and ninety-six, respectively. The Kew magnetometer was used to make forty-eight observations of declination and seventy-five of horizontal force, and forty-eight observations of dip were taken with the earth inductor. On August 9 determinations of the scale values of the horizontal-force and vertical-force magnetographs were made, the values obtained being 0·0000327 and 0·0000113 c.g.s. unit per mm., respectively. Tables show the principal magnetic storms during the year, the mean values of the magnetic elements, derived from hourly values, and also the changes in the mean values for 1949 and 1950. The staff of the Observatory includes a total of thirty-two in addition to the director, Mr. N. R. McCurdy. In spite of wide advertising, the two new posts of meteorologist and assistant meteorologist had not been filled at the time of printing the report.

Sectioned Model of the Earth in Manchester Museum

An account of a sectioned globe, which has recently been installed in the Manchester Museum, is contained in the May issue of the *Museums Journal*. The globe is 30 in. in diameter, and emphasis has been placed on data and the lines of evidence bearing on the earth's interior. Current theories are summarized, and a special constructional treatment is reserved for the evidence of earthquake waves. The core and inner core—revealed by earthquake waves—are made to project into the quadrant cut between the planes of the equator and Greenwich meridian. The colour of the globe is a compromise between a reflexion of the possible true colours of the earth's interior, and shades that are arresting and aesthetically satisfying.

Power Sources in Arid Zones

A meeting to discuss the development of sources of power in arid zones through wind and solar energy is to be held by the Advisory Committee on Arid Zone Research of the United Nations Educational, Scientific and Cultural Organization during September 29–October 1. The Committee will also consider other questions related to this field, including the setting up of an Arid Zone Development Centre. The meetings are to be held in the rooms of the Royal Society, London, W.1. The Advisory Committee on Arid Zone Research consists of the following members : Dr. Hassan Awad, secretary-general of the Royal Geographical Society, Egypt , Mr. Richard L. Boke, regional director of the Bureau of Reclamation for California ; Dr. B. T. Dickson, liaison officer for the Executive Committee of the Commonwealth Scientific and Industrial Research Organization, Australia ; Mr. A. N. Khosla, additional secretary to the Government of India at the Ministry of Irrigation and Power, New Delhi ; Prof. Roberto Llamas, director of the National Institute of Biology, Chapultepec, Mexico ; Prof. Joseph Peres, University of Paris ; Prof. L. Picard, director of the Israeli Geological Institute ; Dr. H. G. Thornton, head of the Soil Microbiology Department at the Rothamsted

Experimental Station at Harpenden, Herts; and Dr. Jacobo Zender, director-general of agriculture at the Ministry of Agriculture, Peru.

Commonwealth Fund Fellowships for Advanced Study and Travel in the United States

A NUMBER of Commonwealth Fund fellowships are again being offered by the Commonwealth Fund of New York (1 East 75th Street, New York 21) to British subjects, for advanced study and travel in the United States. All expenses of travel, study and living will be met, with some adjustment of stipends for married men with families. The fellowships, which are open to British men and women who are not normally resident in or near the Americas and who have not previously worked or studied for more than a few months in the United States, are offered annually in six categories as follows. *General:* twenty fellowships to graduates of a university in the United Kingdom of Great Britain and Northern Ireland. Candidates must be available in London for interview in March 1953; age, 23–35; tenure, 12–21 months; applications by December 15. *Home Civil Service:* five fellowships to permanent members in the higher ranks of the Civil Service in Great Britain, three for the administrative grades and two for the scientific and professional grades; age, less than 40; tenure, 6–12 months; applications by December 31. *Dominion Civil Service:* five fellowships to Civil servants in the Governments of Australia, New Zealand and South Africa; age, less than 40; tenure, 12–21 months; applications by December 31. *Colonial Civil Service:* two fellowships to Civil servants in the Governments of British Colonies, Protectorates and Trust Territories; age, less than 40; tenure, 6–12 months; applications by November 15. *Journalism:* three fellowships to journalists practising in the United Kingdom and engaged on the opinion-making or broadly editorial side of their profession; age, 23–35; tenure, 9–15 months; applications by December 31. *American Studies:* four fellowships will be available to faculty members appointed to or holding posts in American studies in universities in the United Kingdom, candidates to be nominated by their universities; tenure, 4–12 months (these fellowships are not limited by previous study in the United States). Application forms and further details of these fellowships can be obtained in Britain through universities or government departments, or from the Warden, Commonwealth Fund, Harkness House, 35 Portman Square, London, W.1.

Nature Conservancy Research Studentships

THE Nature Conservancy has made the following awards for 1952 of research studentships for postgraduate training in ecology, tenable for periods up to three years at the institutions indicated: *Botany,* B. N. Bowden (Lincoln College, Oxford), Miss B. Douglas (Freshwater Biological Association, Ferry House, near Ambleside), J. D. Lovis (University of Leeds), K. J. F. Park (King's College, Newcastle upon Tyne) and I. H. Rorison (University College, Oxford); *Zoology,* A. B. Acton (Keble College, Oxford), J. M. Cullen (Wadham College, Oxford), M. J. Davies (Exeter College, Oxford), and A. M. Jordan and D. H. Murphy (University of Durham); *Physiography,* D. H. Maling (University of Durham).

The Night Sky in October

FULL moon occurs on Oct. 3d. 12h. 15m., U.T., and new moon on Oct. 18d. 22h. 42m. The following conjunctions with the moon take place: Oct. 6 10h., Jupiter 7° S.; Oct. 20d. 10h., Mercury 4° N. Oct. 21d. 15h., Venus 4° N.; Oct. 24d. 11h., Ma 1° N. Mercury is too close to the sun during mo of the month for favourable observation. Venus, a evening star, sets at 18h. 25m., 18h. 0m. and 17 50m. on October 1, 15 and 31, respectively. I stellar magnitude is − 3·4, and 0·90–0·83 of t illuminated disk is visible. Mars is an evening sta setting at 20h. 10m. in the middle of October and on ten minutes later and earlier at the beginning a end of the month, respectively; the stellar ma nitude varies between 0·6 and 0·8. Jupiter rises 19h. 10m. on October 1 and about two hours earli at the end of the month. Its stellar magnitude − 2·4, and during October it is a little south δ Arietis. Saturn is in conjunction with the sun o October 11 and is unfavourably placed during t month for observation. Occultations of stars bright than magnitude 6 are as follows: Oct. 5d. 20h. 08·9m μ Arie. (*R*); Oct. 6d. 21h. 53·5m., 17 Taur. (*D*) Oct. 6d. 22h. 10·6m., *q* Taur. (*D*); Oct. 6d. 22 18·4m., 20 Taur. (*D*); Oct 6d. 22h. 37·5m., 17 Tau (*R*); Oct. 6d. 22h. 51·8m., 16 Taur. (*R*); Oct. 6 23h. 06·3m., *q* Taur. (*R*); Oct. 6d. 23h. 22·1m 20 Taur. (*R*); Oct. 6d. 23h. 26·9m., 21 Taur. (*R*) Oct. 29d. 0h. 21·4m., 232 B.Aquar. *m* (*D*); Oc 30d. 20h. 04·3m., 51 Pisc. (*D*). *D* and *R* refer t disappearance and reappearance, respectively, an observations are for Greenwich. The Orionid mete shower occurs about October 20–23; the radiant this shower is at R.A. 6h. 24m., dec. 15°. The suppose connexion between this stream and Halley's Com has been disproved by the work of Prof. A. C. Lovell, of Manchester, who has shown from determination of the velocity of meteors from th shower that the period must be comparatively sho and hence the shower cannot be associated wit Halley's Comet, the period of which is about 76 year The same conclusion applies to the η Aquarids earl in May, which were also believed to be associate with Halley's Comet.

Announcements

THE sixth Rutherford Lecture of the Physic Society will be given on October 3 at 5.10 p.m. i the Lecture Theatre of the Science Museum, London S.W.7, by Prof. R. E. Peierls, professor of theoretic physics in the University of Birmingham; he wi speak on "The Atomic Nucleus and its Con stituents".

AT an open day which is being held at the Fulm Research Institute, Stoke Poges, Bucks, on Septem ber 30, a memorial plaque to the founder, Colon W. C. Devereux, will be unveiled by Lord Hives, o Rolls Royce, Ltd.

BY an Order of the Committee of Privy Counc for Medical Research, Sir Geoffrey Vickers has bee appointed to be a member of the Medical Researc Council. By the same Order made in this respec after consultation with the Medical Research Counci and with the President of the Royal Society, th following have also been made members of th Council: Prof. G. R. Cameron, professor of morbi anatomy in University College Hospital Medic School, London; Prof. A. J. Lewis, professor o psychiatry in the University of London; and Si James Spence, Nuffield professor of child health i the University of Durham.

EDUCATION OF THE DEAF

DURING the recent meeting of the British Association at Belfast, the session of the Education Section (L) on the morning of September [illegible] was devoted to three papers and a discussion on he education of the deaf. Mr. A. L. Binns, president of the Section, took the chair and there was a large attendance.

The first paper, by Sir Richard Paget, on "The Education of the Totally Deaf", was read in his absence by Mr. E. S. Greenaway, headmaster of the Yorkshire Residential School for the Deaf, Doncaster. Sir Richard put forward conclusions about the relationship between human speech and thought, the origins of speech and the possibilities of lip-reading. He reported that he and his collaborators had evolved a new language of manual signs. He recommended that this should be learned by the mothers of young children who were found to be totally deaf, and taught by them to their children, before speech.

In a second paper, Mr. R. Askew gave an account of the establishment, in 1946, of the first secondary grammar school for the deaf, the procedure adopted in selecting candidates for admission, usually at the age of 13 +, the curriculum and out-of-school activities, the social life of the school, and the educational achievements and range of careers followed by its pupils.

Lastly, Prof. A. W. G. Ewing (University of Manchester) presented a summary of the results of investigations into the capacity of very young deaf children to learn and comprehend speech through lip-reading, into variations in the mental abilities, aural histories and residual capacity to hear of pupils in special schools for the deaf and partially deaf, the use of hearing aids and the ages at which children are ascertained to be deaf. Prof. Ewing illustrated his paper by a short documentary film "Children learning to Lipread". This showed how parents learn to train their children to watch for speech and to understand it through lip-reading, by engaging them, informally, in activities appropriate to their ages and interests.

Sir Richard Paget said that the mentality of uneducated children who are totally deaf is "utterly primitive". Handicapped by wordlessness, they can copy the actions of others and learn the techniques of various trades, but they cannot originate and cannot think logically, because "logical thinking depends upon the rearrangement of 'units of thought', such as our words: but the units of thought of the uneducated deaf are so vague, diffuse and shapeless that they cannot be fitted together with any precision". Their minds work differently from ours; they are probably a million years behind the times.

There is a very close relation, Sir Richard said, between expression by manual pantomime and expression by the tongue, lips and other oral gestures which carry the meaning of human speech. The noises of speech are quite secondary. They carry the gestures. Speech without sound is an effective means of expression, although intelligible only to a good lip-reader. The 'secondary' noises which accompany speech express the emotional state of the speaker. There is what Charles Darwin called "some kind of sympathy" between the movements of man's hands and those of his mouth. Originally, primitive man (with a mentality probably similar to that of present-day uneducated deaf mutes) must have expressed his ideas by pantomime; but "without knowing it, his mouth mimicked his hands".

Oral methods of educating the deaf aim at making the deaf appear to be normal, for example, by good lip-reading, good articulation and a sufficient vocabulary to enable their pupils to carry on simple conversation. But speech and lip-reading are extremely difficult for all but the exceptionally gifted deaf. Successful lip-reading is dependent on good sight and a clear speaker. It is not practicable in large gatherings, such as at a cathedral service. Many of the claims that are made of the successful teaching of speech to the deaf have related to cases of residual hearing, or of deafness appearing after the deaf pupil has already learnt to speak. Only a relatively small percentage of the deaf is actually totally deaf.

Generalized pantomime, Sir Richard commented, is a blind alley, which ignores the use of words. The oralists have been right in condemning the use of natural sign language. With the collaboration of Prebendary Albert Smith, of the Royal Association in Aid of the Deaf and Dumb, and others, Sir Richard said he had evolved a "systematic sign language", in which each sign is the equivalent of a spoken word. He thought that if such a language were used in communicating with a young totally deaf child, as a hearing mother talks to her young deaf child, it is probable that this deaf child would pick up the signs as easily as a hearing child picks up words. In this way the deaf child might acquire a vocabulary of verbal signs which it would use at first in the place of spoken words. At present this vocabulary of the new sign language amounts to about 3,000 signs, of which 900 are designed for quite young children. The principal signs of the children's vocabulary have recently been filmed by the Wellcome Foundation. In 1948 Mr. Greenaway sent one of the oral teachers from his school to London to learn this children's vocabulary. She learned the 900 signs at the rate of 240 signs an hour. Her whole instruction period was only eight hours, and she demonstrated her knowledge by signing one of Edmond Dulac's Russian fairy stories, after going through it once with Sir Richard. A systematic sign language would be incomparably easier to acquire than any spoken language.

Mr. Greenaway said that he firmly believed the oral method of education to be basic for all deaf children. He is concerned about pupils who are taught orally, but unsuccessfully. He believed that research, in the use of hearing aids, for example, would open up many possibilities of better education for the deaf in the future. But "a deaf child who has failed at school has failed to live". Of twenty deaf boys and girls who had left his own school this year, one had gained admission to the Mary Hare Grammar School for the Deaf, three had attended courses of technical training outside the school for the deaf; before leaving, four others were certainly oral successes, and four more would probably be described as oral successes. He was concerned about the rest. He felt that for children like them something should be added to oralism.

In a short discussion which followed, it was suggested that signing, if encouraged in a school for the deaf, might become a substitute for ordinary language. Finger-spelling was suggested by one speaker as a chief method of education, and another speaker asked if the introduction of a variety of methods would not create confusion in schools for the deaf.

Mr. R. Askew said that the Mary Hare Grammar School for the Deaf, which was first opened in 1946, with 44 pupils, now provides 75 places. It is wholly oral, like the two private schools for the deaf from which it took its roots and which it replaced as centres in which secondary education is available to the deaf. In describing the aims of the Mary Hare School, Mr. Askew quoted the late Sir Fred Clarke—"to liberate the intelligence of our pupils, in and through active membership of society"—in this case by the achievement of the pupils, although deaf, of capacity to participate in the hearing, talking society of the general community. To gain this, the pupils have to have confidence in their abilities, particularly their capacity to lip-read and in general knowledge, which they must be able to enrich by reading.

The procedure adopted for selecting candidates for admission is: (*a*) notification to local education authorities of the holding of an entrance examination, (*b*) a preliminary screening test, by written papers in English, general knowledge and arithmetic, taken by candidates in their schools, followed, in the cases of those who attained the required standard, by (*c*) a visit to the Mary Hare School, during which the history of each candidate is studied, in the light of reports from head teachers, tests to determine hearing loss, the results of performance tests of ability and a vocabulary test, and assessments of personal and social behaviour in which all members of the teaching staff participate. The mental testing is carried out with the collaboration of the Department of Education of the Deaf, University of Manchester. On admission, the pupils who were born deaf are from two to three years retarded in vocabulary.

Each school day begins with an assembly at which a hymn is sung, followed by half an hour during which speech training is provided to meet individual needs. Wearable hearing aids are used by many pupils. 'School subjects' are taken by specialist teachers. A weekly 'library period' is an important part of the curriculum of each form. Extra-curricular activities include community singing, free access to a studio for painting and drawing, athletics in which the pupils compete with those of schools and organizations for ordinary boys and girls, hobbies and pets, a pig club and a school magazine, managed by a committee of the pupils.

In 1949, of twelve candidates who sat for the School Certificate Examination, all were successful. Since that year a number of pupils have gained the General Certificate of Education (two at the higher level). This year two pupils are proceeding to universities, one with a State scholarship. Not all pupils are expected to take the General Certificate. The aim of a wider culture is more important. Former pupils follow a wide range of occupations; for example, one, an assistant in the pathological laboratory of a hospital, is now studying for a university degree, and another is a quantity surveyor. All are working happily side by side with ordinary people, who accept them as fellow-workers. Eleven former pupils are continuing their studies by correspondence courses.

The number of schools for the deaf in Britain presenting candidates for admission has grown from ten, in 1946, to twenty-six in 1952. The existence of the Mary Hare Grammar School appears to be an incentive to teachers of the deaf elsewhere, and their pupils, to aim at higher standards.

In answers to questions, Mr. Askew said that the Mary Hare School is staffed by seven fully qualified teachers of the deaf and two teachers who are working for a special qualification. Incentives are used to encourage pupils to rely solely on speech and lip reading as a means of direct communication. The tendency of newcomers to resort to signs is "dying out".

Prof. Ewing's paper summarized developments in the educational treatment of deafness in children that have resulted from modern scientific research in Britain and the United States, and included references to investigations made in the Department of Education of the Deaf, University of Manchester, with financial support from the Medical Research Council and the Leverhulme Trustees. It has been found that the onset of dumbness, due to deafness, can be prevented in earliest infancy. Children of two years old have learnt to lip-read and begun to talk spontaneously, as a result of skilful training in their homes. This possibility was first discovered when the parents of a deaf girl, aged one year and two weeks, demonstrated that, under the guidance of Dr. I. R. Ewing, they had trained her to lip-read and respond by specific acts of behaviour to six different phrases spoken in a natural and conversational manner. She was one of more than thirty deaf children, whose ages ranged from twelve weeks to nearly three years, who had similar training during 1947. By the age of two and a half, some of them became able to understand, through lip-reading a vocabulary of up to 500 words and phrases.

It has been shown that deafness can be effectively ascertained during even the earliest weeks of life. Special tests for this purpose, based on the results of a study of the ways in which ordinary children develop capacity to respond to sound, have been evolved.

Of 781 children referred by medical officers and otologists to the Department of Education for the Deaf, University of Manchester, during 1948–51, for tests and educational guidance, those of two years old form the largest age-group. A majority of the pupils who at present are admitted to schools or classes for the deaf or partially deaf have had their handicap since before the age of two years; but many cases of partial deafness and some of severe deafness are not ascertained until after the children's admission to ordinary schools.

Great variations have been found in the stages of linguistic development which have been reached by deaf and partially deaf children when first seen. Of 430 children referred before the age of five years, almost all used their voices purposefully and some, especially of those who had become deaf after the age of one year, had a certain amount of imperfect speech. Of 351 boys and girls of school age, a majority were already talking, although very often imperfectly. Fewer than five per cent of pupils in schools for the deaf are unable to hear any sound. Experiments have shown that hearing-aid equipment can be designed and constructed to enable children who are very severely deaf to hear speech to an extent that stimulates their linguistic development and facilitates their general education. Children who, without this equipment, cannot hear any sound of conversational speech, unless uttered within a distance of two inches from their ears, have learnt to combine skill in the use of hearing aids with proficiency in lip-reading. Investigations are in progress to find ways that are economically practicable for making school rooms acoustically fit for the effective use of powerful hearing aids, and ways of modifying hearing aids to enable very young children who are severely deaf to benefit from continuous auditory experience.

During the course of a brief final discussion, Prof. Hallowell Davies, of Washington University, St. Louis, said that in the Central Institute for the Deaf, with which he is associated, it has been found that children who are admitted to the nursery unit, at an early age, are much less liable to linguistic retardation than those who enter school later. No 'signs' have ever been used in the Institute.

As a personal comment, the present writer regrets that the first paper at the meeting tended to focus attention on the use of 'signs' as a means of communication with the deaf, and to divert it from consideration of the outstanding success with which secondary education for the deaf has been established at the Mary Hare Grammar School, which is a unique institution of exceptional interest to educators and psychologists. A dictionary of organized signs, prepared by the Abbé Sicard, who published in 1823, still exists ; its use was long attempted in France but was abandoned many years ago.

MEASUREMENT AND IMPORTANCE OF ELASTIC PROPERTIES OF METALS

A CONFERENCE was held at the National Physical Laboratory, Teddington, during March 20–21 on the "Measurement and Importance of the Elastic Properties of Metals", to discuss the measurements of elastic constants which have been going on in the Laboratory and elsewhere, and to consider how the information obtained from them could be used by metallurgists. It was attended by between eighty and ninety representatives from universities, industrial concerns and government departments. The first day was devoted mainly to describing experimental techniques and the results which have been obtained from them, while on the second day the speakers considered how elastic constant measurements could contribute to new knowledge of the physics of solid states.

The first paper was by Mr. A. F. C. Brown (National Physical Laboratory), on the "Static Measurement of Very Small Strains". He pointed out that in order to measure strain to an accuracy of $\pm$ 1 per cent it is often necessary to measure changes of length of less than 10^{-6} in. Even higher precision is needed if a study is being made of small variations in elastic constants, and great difficulty is experienced in transferring the strain to the extensometer without introducing significant errors. Generally, the most suitable methods are those in which the extension of a standard length of a specimen is made to rotate a mirror ; but direct microscopic examination of length changes, and interferometer techniques, have also been used. It is very important to ensure that the desired type of loading is achieved, and this has been the subject of considerable research in the National Physical Laboratory.

In a paper on "Medium and High Frequency Measurements of Elasticity", Mr. G. Bradfield (National Physical Laboratory) described the methods in use at Teddington for the dynamic measurement of elastic constants, pointing out that, except at very high frequencies, the moduli vary somewhat with rate of straining. This was illustrated by results with polycrystalline aluminium from 0·4 c./s. to 50 kc./s. over a temperature range of 30°–700° K.

Methods using pulse-travel times and frequencies of 1–20 Mc./s. are very useful for measuring elastic constants of single crystals, and accuracies of a fraction of 1 per cent have been obtained with crystals of a few millimetres in size. On fine-grain polycrystalline bars about 10 cm. long, accuracies of 0·03 per cent are possible. Generally, the quartz crystal transducers used are mounted on steel or fused quartz blocks, which are applied to the specimen under test. Although separate transducers for transmitting and receiving have been most widely used at the National Physical Laboratory, many measurements with a single probe on both solid and liquid specimens have been made at high temperatures, and an attempt is being made to reach 1,550° C. in this way.

Of many alternative resonance methods, those using magnetostrictive transducers (which can produce both rotational and irrotational vibrations) are preferred, and have been used from near absolute zero to 500° C. ; 1,000° C. is the probable limit with the present equipment. Inductor methods have been used for specimens weighing as little as ¼ gm. The best accuracy obtained by resonance techniques is a few parts in 10^4 in the elastic moduli.

For bars, the lateral inertia effect on velocity enables Poisson's ratio to be determined very accurately, and deviation from ($\frac{1}{2}E/G - 1$) indicates anisotropy quantitatively, and thence the true constants for an isotropic material can be calculated, as described in the following paper.

Mr. H. Pursey and Mr. T. H. Schofield (National Physical Laboratory, Physics Division and Metallurgy Division, respectively) presented a paper on "Elastic Constant Measurements on Some Alloys". Measurements of the elastic moduli of a series of α-solid solutions of copper with elements of the first long period show principally a fall in modulus as the percentage of stranger atoms increases, and for a given atomic percentage of solute the higher the number of valency electrons the greater the depression in elastic moduli. They pointed out, nevertheless, that plotting elastic moduli against electron concentration does not bring the four curves together, and it is clear that they cannot be brought together by plotting against any power of electron concentration. Zener's theory of the misfit effect between solute and solvent atoms was outlined, but this too fails to explain the results satisfactorily. A further anomaly exists at very low atomic percentages, where it is found that the effect of introducing small amounts of stranger atoms is, in fact, to raise the moduli above those obtained for the pure metal. This may be due to the tendency of the foreign atoms to provide 'anchor points' for dislocations, thereby strengthening the material.

The remainder of the paper was devoted to an explanation of the mathematical technique whereby the elastic constants of an isotropic material may be derived from measurements on an anisotropic specimen of the same composition, assuming the anisotropy to be due to preferential orientation of grains, and that the lattice has cubic symmetry. The corrections are functions of the single-crystal constants, and proportional to the fractional difference between ($\frac{1}{2}E/G - 1$) and Poisson's ratio as determined from the lateral inertia effect on longitudinal vibrations.

Since the functions vary slowly with the single-crystal constants, these need only be known to a relatively low degree of accuracy.

A discussion followed these papers, and in reply to a question by Dr. E. Billig, of Associated Electrical Industries, Ltd., Mr. Bradfield said that although propagation of waves up to 3,000 Mc./s. in solids has been reported, serious difficulty is likely to arise from scatter in polycrystalline materials. Replying to an inquiry, Mr. Bradfield said that the strains used in the resonance method were of the order of 5×10^{-7}.

The next paper was by Dr. E. G. Stanford (Aluminium Laboratories, Ltd.), and was entitled "The Variation of Young's Modulus of Aluminium Alloys with Temperature". He described measurements of the Young's modulus of aluminium by the resonance technique, using the fundamental mode of longitudinal vibration. The materials used were super-purity aluminium (99·992 per cent), commercially pure aluminium (99·5 per cent), an aluminium–manganese alloy (1¼ per cent manganese) and an alloy of the duralumin type. The specimens were subjected to heating and cooling processes, the rate of change of temperature being about 2° C. per minute, and measurements of Young's modulus were taken at intervals of 10° C. between room temperature and the melting points.

The results show a discontinuity in the Young's modulus/temperature curves at the recrystallization temperature, accompanied by an increase in internal friction. Precipitation from solid solution also causes a slight discontinuity for alloys which show age-hardening characteristics. The modulus of both the pure material and the alloys is generally decreased by cold work, and cannot always be made to recover by annealing. Recovery did not occur, for example, in the case of annealed super-purity material which had been strained 10 per cent in tension; however, when recovery does take place, it is greater in the case of the super-pure than in the commercially pure material. At 10 kc./s., relaxation occurs at a temperature of about 500° C. in the super-pure material, accompanied by an increase in internal friction. No such effects were observed at any temperature up to the melting point in the case of the impure materials. Dr. Stanford hoped that further work on the behaviour of alloys near their melting points would enable improvements to be made in casting techniques.

The final paper of the first day was by Prof. N. F. Mott (University of Bristol). He discussed the effect of temperature on the elastic modulus. The drop in the shear modulus is due partly to thermal expansion, there being no first-order change of entropy with shear, and hence no change of temperature on shearing. Some theoretical calculations have been made by Prof. Max Born's school for solid rare gases, but none for metals. He also discussed the effect of cold-work on the elastic modulus. He considered that a drop in the shear modulus of five to ten per cent is to be expected, and that this is due to the screw dislocations trapped in the lattice and not to the edge dislocations, the latter probably forming sessile (immobile) groups, for example, in deformation bands. The partial recovery of the elastic moduli after a low-temperature anneal, observed recently by A. D. N. Smith, should be due (like cross slip) to the mutual annihilation of screw dislocations, and a similar dependence on temperature is to be expected.

The morning session of the second day opened with a paper entitled "Theory of the Elastic Constants of Metallic Crystals" by Prof. H. Jones (Imperial College of Science and Technology, London), who explained that on modern electron theory the cohesive energy of metals may be regarded as arising from (*a*) the exchange interaction between the ionic shells (*b*) the energy of the lowest state of the conduction electrons (spherical approximation), (*c*) a correction to (*b*), the electrostatic potential term, and (*d*) the Fermi energy of all the conduction electrons. Since in different metals these terms have differing relative importance and variation with strain, it is now becoming possible, by comparing theory and experiment to understand the dominant effects in the elastic constants of a particular metal or alloy. For example where the ion radius is considerably less than the atomic radius, as in sodium, the term (*a*) will be small and the electrostatic contributions predominate These are very anisotropic and hence in accord with the observed elastic constants of sodium.

The effect of strain on the Fermi energy can be illustrated by considering shearing distortion of the first Brillouin zone in the face-centred cubic case If there is only one electron per atom, the Fermi surface is well within the zone and is little altered by shear; but if there are 1·5 electrons per atom, the surface touches the zone, and shear causes a tendency of electrons to leave the zone. The larger the surface of contact the greater is the change in energy and hence the greater contribution to the elastic constants. Some results on β-brass in general accord with these ideas were then described. Prof. Jones pointed out that the treatment is most satisfactory for atoms where there are clearly marked closed shells and few valency electrons, such as copper, silver, gold, sodium, magnesium; in conclusion, he emphasized the need for experimental observations from single crystals.

In the subsequent discussion, Prof. Mott asked if there is any connexion between elastic constants and the diamagnetic effects at low temperature in aluminium and bismuth associated with small groups of electrons overlapping the zones. Prof. Jones replied that in any metal the Fermi surface is very complicated, and the diamagnetic effects are considered to arise from small parts of the surface of very high curvature, whereas the elastic constants are associated with large overlapping. In answer to a question by Prof. J. D. Bernal, Prof. Jones agreed that he would expect interesting differences between the hexagonal metals of long and short axial ratio, for example, magnesium and zinc, and would value some experimental observations. In particular, the measurements should be made at different temperatures in order to give an idea of the absolute zero values. This is important, since it enables some elimination of the influence of temperature and internal strain on the elastic constants, for internal strain has an effect decreasing with temperature. Dr. R. Street (University of Nottingham) mentioned that there is a considerable change in Young's modulus in passing through the Curie temperature, and in reply Prof. Jones said that he felt the present treatment could give no satisfactory explanation of this effect.

Dr. W. A. Wooster (University of Cambridge) spoke on "Diffuse X-ray Reflexions from Crystals in Relation to Elasticity and Structure". Dr. Wooster outlined the fundamental principle that perturbations in the atomic lattice produce additional diffuse reflexions between the normal spots on a Laue pattern. Alternatively, with monochromatic radiation the diffuse reflexions are observed when the crystal is rotated a small angle from the correct Bragg setting, that is to say, there is a spread of the reciprocal lattice points. By studying the diffuse reflexions near a particular point, attention is fixed on the thermal elastic waves of particular wave-length and wave-normal. From measurements of intensity the velocity of the waves can be derived and hence the elastic constants.

There are two main experimental methods: recording the reflexions on a photographic plate and using a microphotometer, or direct measurement of the intensities with a Geiger–Muller counter spectrometer. The former is less accurate, about ± 5 per cent, but has the advantage of showing the pattern of the reflexions. The Geiger–Muller method requires more elaborate equipment, namely, a highly stabilized X-ray source or a monitoring system, but can give an accuracy of about ± 3 per cent. Absolute measurements of the intensity of the X-ray beam, necessary if absolute values of the elastic constants are required, are less accurate (probably ± 10 per cent) owing to the difficulty of comparing the diffuse reflexions with a direct beam some 10^4 times stronger. The essential difference between this and all previous methods of measuring elastic constants is that the crystal is subjected to no external mechanical stress whatsoever. The constants, moreover, refer to very high frequencies, that is, wave-lengths in the region 0–200 A. There are few results yet obtained on metallic substances, the most important being those of Ohlmer on aluminium, who found marked dispersion for wave-lengths below about 10 A.

Dr. R. S. Leigh (Imperial College of Science and Technology, London) spoke on "Relations between Elastic Constants and Phase Boundaries in Alloys". Dr. Leigh explained that the free energy, F, of an alloy can be expressed as $F = E_0 + (E_v - TS_v) - TS_m$, where E_0 is the electronic energy at absolute zero; $(E_v - TS_v)$ is the lattice vibration term, E_v being the internal energy and S_v the entropy; and S_m is the mixing entropy in the case of a disordered solid solution. The equilibrium state of the alloy at a given temperature is, of course, that state which has the lowest free energy. An example of a theory based on the effect of lattice vibrations is that of Zener explaining the V-shaped phase boundaries of disordered body-centred cubic β-phases. This requires that the β-phase should have a lower Debye temperature than neighbouring phases. Zener has suggested that this is due to repulsive ion–ion interaction which in turn leads to a low value of $\frac{1}{2}(C_{11}-C_{12})$, a low cut-off frequency in the Debye treatment and hence a low characteristic temperature.

Considering the aluminium–zinc system, the solubility gap implies that here the mixture of the α- and α′-face-centred cubic structures has a lower free energy than an equivalent homogeneous phase. Thus the free-energy curve must be such as to have a common tangent at two points. The theory put forward to explain this is based on the idea of shearing the Brillouin zone, the overlapping electrons giving a negative contribution to the shear constant. The calculation leads to phase boundaries of the gap at 75° C. of 20 and 70 atomic per cent in comparison with observed values of 16 and 59 per cent. In conclusion, Dr. Leigh stressed the value of elastic constant measurements on single crystals, in particular in this field on solid solutions of aluminium with zinc, silver, lithium and magnesium.

The afternoon opened with a paper by Prof. C. S. Barrett (University of Birmingham), in which he discussed the after-effects in metals following plastic deformation and showed that they depend on the time occupied by the stress-cycle. He explained the after-effects in terms of anchoring and release of dislocations in the material. In discussion, it was pointed out that recent work at Bristol, in which care was taken to ensure that a homogeneous stress system was obtained, confirmed Prof. Barrett's views.

In the final paper, Mr. H. L. Cox (National Physical Laboratory) referred to the general issue of stability. He stated that failure by structural instability within the elastic range is always a possibility, and that it is quite easy to devise laboratory models which would collapse in this way under any prescribed form of loading; until the nature of the true forces of cohesion within a solid material is better understood, the possibility that the strength of the material is limited by elastic instability should not be overlooked.

After a short discussion, Dr. N. P. Allen, in closing the conference, expressed the hope that the National Physical Laboratory would have similar opportunities in the future for bringing the results of specialized research into closer relation with technological interests.

STANDARDS OF LIFE IN LESS-DEVELOPED AREAS

TWENTY years or so ago, the number of surveys of living conditions carried out each year in the 'less-developed' as well as in the 'more-developed' countries began to increase rapidly, reaching its peak just before the Second World War. This was, of course, due in the first instance to efforts on the part of administrative agencies to collect information on the basis of which action could be taken to combat the consequences of the economic depression—or sometimes, perhaps, to justify a reluctance to discharge responsibilities of this kind. A large amount of information has thus been made available as a by-product of government activity, rather than as a result of scientific research properly so called. The reports in which this information is presented have been collected by the United Nations Department of Social Affairs*, and an opportunity has now arisen to see what they amount to, and to evaluate their reliability.

The task is an important one, partly because of the urgent need for dealing with the problems of poverty and squalor in the less-developed countries, and partly because it is high time that administrative agencies so plan their work as to make available as much raw material as possible for scientific research. The range of social problems in the international field is so vast that it is unlikely that *ad hoc* researches can be undertaken to throw light on them. The proper planning of national and local surveys to secure comparability of the results is therefore an obvious necessity.

The first report which the Department of Social Affairs has published in the series dealing with inquiries into household standards of living in less-developed areas surveys the organization and geographic and demographic range of field-investigations of the income, expenditure and food consumption of households in Africa, Asia, the Caribbean, Latin America, and the Pacific. It is issued as the first part of a Survey of which the ultimate aim is "to provide a critical commentary on such information on standards of living in the less-developed areas of the world as is at present available". This is a task that is as ambitious as it is praiseworthy, for as the information available from the inquiries that are surveyed is narrow both in its range and its scope, the Survey will perforce "constitute a study of the limitations rather than of the extensiveness of the data now available".

---

* United Nations. Enquiries into Household Standards of Living in Less-Developed Areas: a Survey of the Organization and Geographic and Demographic Range of Field Investigations of the Income, Expenditure and Food Consumption of Selected Households in Africa, Asia, the Caribbean, Latin America and the Pacific. Pp. viii+101. (New York: United Nations; London: H.M. Stationery Office, 1951.) 2 dollars; 16s.

This statement must be somewhat depressing to those whose interest in living conditions is administrative rather than scientific; something more might have been hoped from a study of twenty years of work in this field, because the aspects of the conditions which are dealt with by the Survey (consumer income and expenditure and domestic food consumption) are those concerning which it is most easy to produce quantitative data. The first volume of the Survey, however, makes it plain that the inquiries so far conducted are seriously defective in many respects. In the first place, the households which are the subjects of the investigations have almost invariably been selected from the members of social, economic or occupational population groups, the majority living in single localities. As a result, the geographical range of the strict applicability of the findings is narrow, often being confined to the locality concerned; few instances of comparability between inquiries conducted within the same territory have been found, and virtually no instances at all of direct comparability between inquiries conducted in different countries or territories. The general conclusion on this score is that, although the areas in which the inquiries were conducted are widely dispersed, they constitute "a relatively insignificant fraction of the total inhabited surface of the less-developed portion of the world", and, "in most cases, of particular less-developed countries or territories".

The inquiries are also defective in a rather more technical sense. Few, even of the relatively small number of inquiries which, it is claimed, deal with an adequate representative sample of the relevant statistical universe, appear to be free from faulty selection procedures, or from a failure to apply the sampling procedures originally decided on when a survey was being planned. "In many cases," it is said, "the methods applied to the choice of the units of investigation either deviated from the target standards of selection, or were not calculated to secure an unbiased choice." The final conclusion embodied in the first volume of the Survey is therefore that "both in respect of the less-developed countries and territories as a whole, and in respect of them individually, the total amount of information available on household income and expenditure and domestic food consumption is, if not negligible, at any rate meagre".

This is not to say, of course, that the work carried out hitherto has been a waste of time for administrative purposes. The statistician may be very sceptical about the results of numerous surveys of the condition of half a dozen or even single households. It is obviously dangerous to base sweeping generalizations on the circumstances, for example, of five families who are thought to be "more or less typical of the average run of Punjab cultivators working between seven and sixteen acres of land each", or on those of two families at San Antonio Huichimal, Mexico. Nevertheless, crude information such as this may be found to vary from case to case only within narrow margins, and to present a picture of basic poverty which is of great political and administrative significance. As is said in the first volume of the Survey, therefore, "in a socially and economically homogeneous environment, data on the living conditions of a small number of judiciously albeit not statistically, selected households, or even of a single typical household, cannot but be an expression of the domestic economies and material circumstances of life of the community as a whole".

In sum, then, even though the Survey demonstrates the need for greatly improved techniques in social surveys conducted in underdeveloped countries, the information elucidated in this way is of great interest, and the "critical commentary" on it which the Survey will produce will be received with gratitude both by social scientists and by administrators.

ELECTROMETRIC DETERMINATION OF OZONE AT HIGH DILUTIONS

By Dr. J. N. PRING, M.B.E., and G. M. WESTRIP

Royal Institution, Albemarle Street, London, W.1

THE chemical reactions which were formerly mainly employed for the estimation of ozone were based on the liberation of iodine from a neutral potassium iodide solution[1]. In the absence of any more accurate or sensitive method, a check on the assumed reaction was lacking, and it is now apparent that this simple procedure is of value only for conducting comparative measurements. On the other hand, the precise spectrophotometric technique[2] which has now been developed and extensively employed in atmospheric tests is difficult to apply in isolated districts and is limited to the measurement of a column of air several kilometres in length.

Extended laboratory trials by us have shown that an electrometric technique provides a highly sensitive method which could be applied to the determination of local atmospheric concentrations by means of a readily portable apparatus. For this purpose a measurement is made of the E.M.F. of a suitable oxidation-reduction system which is determined by the well-known relation:

$$E = \frac{RT}{nF}\ln\left(k\,\frac{[\text{oxidant}]}{[\text{reductant}]}\right) = E_0 + \frac{RT}{nF}\ln\left(\frac{[\text{oxidant}]}{[\text{reductant}]}\right)$$

where k is the equilibrium constant of the reaction, E the potential with a given solution, and E_0 the potential with a solution containing equal concentrations of oxidant and reductant.

Of different reactions which were investigated, the one most suitable and specific for ozone was found to consist of the oxidation of hydrobromic acid with liberation of bromine in accordance with the reaction $O_3 + 2\,H^{\cdot} + 2\,Br' \rightarrow Br_2 + H_2O + O_2$. (At atmospheric pressure and a temperature of 18° C. the E.M.F. of ozone against hydrogen is estimated at 1·9 volts, and that of bromine in a normal solution of bromine ions at 1·066 V.)

The electromotive equation with this reaction takes the form:

$$E = E_0 + \frac{RT}{nF} \ln \left(\frac{[\mathrm{Br_2}]}{[\mathrm{Br'}]}\right) = E_0 + 0{\cdot}029 \log \left(\frac{[\mathrm{Br_2}]}{[\mathrm{Br'}]}\right)$$

at 18° C. The cell, employing the usual arrangement for this type of measurement, consisted of:

+ Pt wire	$3N$ H_2SO_4 $1N$ KBr	$3N$ H_2SO_4 saturated with Hg_2SO_4	— Hg

On passing ozonized air through the left-hand half-cell, the resulting potential is not proportional to the volume passed but approaches a limiting value depending on the concentration of ozone, due to the liberated bromine only accumulating until its rates of formation and vaporization are equal. With a stream of air free from ozone, the potential of the above system ranged, in different experiments, from 0·050 to 0·070 V., the variation arising from the response to the sensitive logarithmic effect of traces of free bromine.

For the standardization of this method, air with various contents of ozone was prepared by admixture with the anodic gas liberated from the electrolysis of sulphuric acid solution. The ozone contents were determined by passing a definite quantity through potassium iodide solution, acidifying and titrating the liberated iodine with $N/1,000$ sodium thiosulphate, a correction being applied for the amount of iodine liberated by oxygen in a blank experiment. The end-point of the titration was determined electrometrically from the oxidation potential. Air of ozone content as thus determined was then passed through the reagent surrounding the platinum wire until the E.M.F. attained an equilibrium value and became constant. The main precautions which it was found necessary to observe are: (1) to complete the purification of the sulphuric acid used by subjecting it to a stream of strongly ozonized air; (2) to introduce in the reagent initially a small amount of bromine by adding a little potassium bromate and then eliminating the bromine by heating on a water-bath to about 90° C.—alternatively a small amount of bromine can be allowed to remain so that the equilibrium value later given by the ozonized air can be approached from the higher value of the E.M.F. thus resulting; (3) the use of mercury to be avoided to make contact with the platinum wire electrode in its glass support; (4) to prevent access to the inner walls of the tube by the reagent into which the gas is led.

Typical laboratory measurements with this cell gave the following results:

Ozone (parts by volume per 10^6 of air)	Final E.M.F., corrected to 21° C.
18·3	0·237 V.
3·5	0·221
1·62	0·206
0·52	0·185
0·20	0·169
0·11	0·154
0·07	0·135
0·055	0·108
0·045	0·079

The circulation of oxygen or ozone-free air was found not to affect the E.M.F. values given, and nitrogen peroxide only caused a displacement if the concentration exceeded 10^{-6}. It is seen from these results that, when employing concentrations of ozone down to about 2 parts in 10^7 of air, the relationship between ozone concentration and potential was approximately in accordance with the following numerical values for the above equation, $E = 0{\cdot}1995 + 0{\cdot}0355 \log [O_3]$ (ozone concentration is in parts by volume per 10^6 of air), in place of the theoretical coefficient of 0·029. The discrepancy is probably due to the chemical method for estimating the ozone, which fails still further for concentrations below 10^{-7}. The results have shown the high degree of sensitiveness of this method, but no check on the applicability of the formula given has yet been possible. The instability of ozone prevents the preparation and maintenance of supplies of known very low concentrations for the purpose of calibration.

Further trials with this hitherto unpublished method have awaited the development of some alternative accurate procedure, and it is hoped that the present note may merit consideration by those engaged in this field.

ABDOMINAL MECHANO-RECEPTORS IN *DYTISCUS* AND *LOCUSTA*

By G. M. HUGHES

Department of Zoology, Cambridge

DURING an investigation of the nervous control of respiratory movements in the water beetle ***Dytiscus marginalis***, electrophysiological evidence has been obtained for the existence of sense organs responsive to these movements. The abdominal movements consist of an active expiratory phase in which the tergites are depressed by contraction of segmental sterno-tergal muscles, and a passive inspiratory phase in which these muscles relax. These movements normally occur 10–15 times per min., but the frequency may be only 6 per min. after dissection of the abdomen.

Electrical activity in the segmental nerves and abdominal ganglia has been recorded simultaneously with the dorso-ventral movements of the abdomen under various conditions. The normal response in the mixed nerves is composed of groups of large motor spikes and smaller sensory ones. The respiratory movements usually persist after severing a single nerve, and activity in sensory fibres can then be recorded from the distal section of the nerve. The activity in single afferent fibres has been studied and several responses similar to those recorded from the mammalian vagus[1] have been observed. These are apparently due to:

(1) End organs from which the frequency of impulses increases during inspiration. The discharge is usually irregular between successive ventilation movements but may become extremely regular (70 per sec.) at the onset of inspiration.

(2) End organs from which the frequency of impulses increases during both inspiration and expiration (Fig. 1). Expiration is commonly succeeded by a silent period before the resumption of an irregular resting discharge.

(3) End organs from which a persistent discharge of impulses is inhibited during inspiration. The resting discharge may cease completely and re-commence with a burst of high frequency at expiration.

Responses of the first two types may be found in nearly all preparations; but type (3) is of less frequent occurrence. No constant relationship has been observed between the nerve or segment and the type of response.

It was of considerable interest to find that responses to low-frequency vibrations could also be recorded from these nerves. Preparations are very sensitive to tapping of the substratum and to whistling in a low register. Such responses to ground and airborne vibrations are usually obtained from end organs that are not responding to the regular breathing movements, and many of the responses to the latter are not interrupted by these stimuli. When excited by pure tones in a sound-proof room, these receptors are found to be sharply tuned to frequencies of about 100 c./sec. The frequency of nerve impulses bears no relation to the frequency of the sound waves but increases as the intensity is raised (Fig. 2*a*). At a given intensity the frequency of discharge in a single fibre remains relatively constant (Fig. 2*b*). Similar observations led Pumphrey[2] to suppose that responses recorded from segmental abdominal nerves of the locust were probably from chordotonal organs and not from auditory hairs as suggested by Pumphrey and Rawdon-Smith[3]. The responses which they recorded were to sounds in the neighbourhood of 1,400 c./sec.

These auditory responses in the locust have been confirmed, and in addition bursts of impulses have been recorded from the segmental nerves during the inspiratory and expiratory movements. Some end organs respond to both the respiratory movements and auditory stimulation, while others are excited by either one or the other.

The precise nature of the receptors involved in these responses is not yet clear. The abdominal cuticle of *Dytiscus* is well supplied with sensory hairs and spines of several types[4], and there are also segmental chordotonal organs similar to those described in the larvæ by Graber[5]. Methylene blue staining has assisted in tracing the branches of nerves from which breathing responses had been recorded, and it has been found that these nerves contain fibres from the segmental chordotonal organs. The structure and position of chordotonal organs has long led morphologists to suppose that they have a proprioceptive function[6]; but little experimental evidence has been adduced for this view. It is generally accepted that chordotonal organs may have an auditory function[3]; and some of the evidence that responses to such stimulation are detected by segmental organs in *Dytiscus* and *Locusta* has been summarized above. There is no *a priori* reason why both sorts of response should not come from end organs of this type, as it has been generally recognised that from a functional point of view this class of sense organs is not as homogeneous as it is morphologically. It is not improbable that different types of chordotonal organs have become differentiated in a way analogous to the receptors of the vertebrate acoustico-lateralis system[7,8].

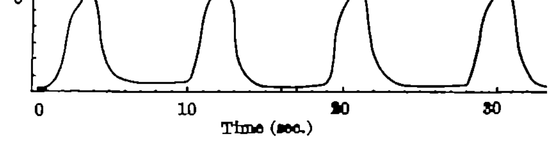

Fig. 1. *Dytiscus marginalis*. Changes in the frequency of impulses recorded from a single afferent fibre in a segmental abdominal nerve. The rhythm of ventilation movements is shown below (expiration upwards)

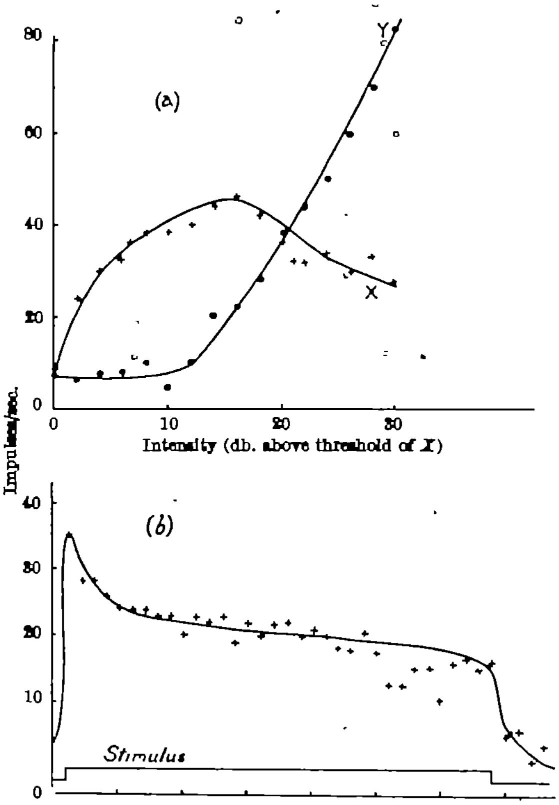

Fig. 2. (*a*) Frequency-intensity curves recorded in two afferent fibres of abdominal nerves in response to sine-wave stimulation at 100 c./sec. (*b*) Curve showing gradual decline in frequency of impulses in fibre *X* during continuous sine-wave stimulation at 100 c./sec.

Whatever the nature of the end organs involved, the responses from the abdominal nerves of *Dytiscus* demonstrate that this insect possesses the sensory equipment to detect sounds of frequencies about 100 c./sec. The flight of these insects in response to sounds and on the approach of footsteps is well known[5]. Furthermore, the responses to the ventilating movements may be of importance in the nervous co-ordination of these movements and may modify the activity of respiratory centres[9,10] which have been suggested in these insects. Such a function is in accord with Eggers's supposition that chordotonal organs may function as 'rhythmometers' which co-ordinate and regulate the rhythmical movements of respiration, circulation and locomotion.

Further results of this work will be published in more detail elsewhere. [March 17.

Internal Fissuring of Wheat due to Weathering

RADIOGRAPHIC technique developed at this Station or the determination of internal or hidden insect nfestation in stored grain[1] has proved to be useful or the detection of other physical anomalies in rains. Practical applications of this sort include the letection of cracked or broken kernels in rough rice paddy) prior to milling[2] as well as the extent of nternal fracturing of certain grains such as maize lue to uneven stresses arising from severe drying onditions. This communication deals with a conlition of internal fissuring occurring in wheat due to veathering of the ripened grain in the field.

Examination of radiographs of numerous samples f non-infested wheat disclosed that some had the ppearance shown in Fig. 1, indicative of sound, ormally matured grain, while others produced ine radiographic shadows indicating the existence f cracks or fissures oriented at right angles to the ongitudinal axis of the kernel (Fig. 2). (The pictures re projection prints of the original radiographs.) lose visual examination of both kinds of grain evealed that those samples which exhibited the issuring were weathered, whereas the sound grain was of normal colour and bright in appearance. Weathered grain loses this sheen and colour, and the kernels present a faded and roughened appearance. This condition is known to be caused by wetting of the mature grain by rain as it stands in the field prior to harvest.

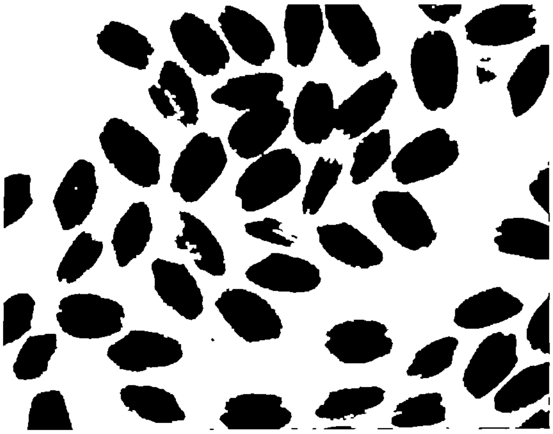

Fig. 1

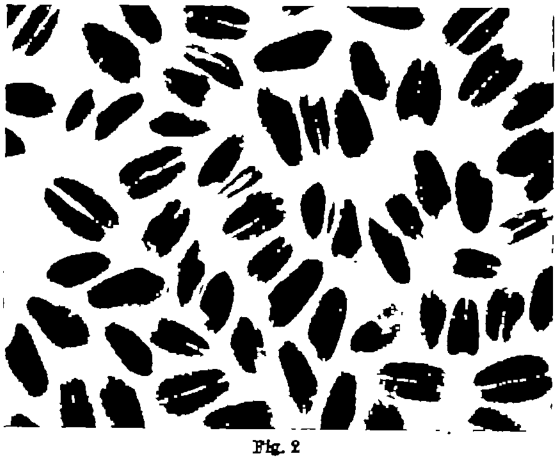

Fig. 2

It is well known that weathered or 'bleached' wheat kernels suffer a decrease in density associated with the swelling caused by wetting of the grain and that this change is not entirely reversible by subsequent drying in the field. This permanent loss in density is related also to the severity and frequency of wetting. It was at one time proposed[3] that this loss in density of grain, which has swelled by wetting and then has been re-dried, may be due to the formation of internal spaces in the endosperm of the grains. The present discovery confirms this hypothesis strikingly. The internally fissured condition has been noted not only in weathered hard red winter wheats from Kansas but also in spring wheats from North Dakota and western Canada.

These observations have prompted laboratory studies to determine precisely the conditions of wetting and drying which cause the fissuring of wheat to occur, as well as the effect of such fissuring on those physical characteristics of the grain which would affect its technological properties. The results of these studies will be published elsewhere.

Rostral Extremities of the Sympathetic Trunks

THE older anatomists believed that the sympathetic trunks were attached to various cranial nerves; but nowadays the conception that they commence above in the superior cervical ganglia is apparently unquestioned, and the internal carotid nerves are described as branches of distribution of these ganglia. Is this modern view correct, or do the trunks really proceed farther in a rostral direction? They probably do, although not in the manner or position indicated by the classical authors. One suggests that the internal carotid nerves are cephalic portions of the sympathetic trunks, and the evidence in favour of this idea will be summarized here and given in detail elsewhere.

The internal carotid nerves, in man and other mammals, are often as thick as, or thicker than, the trunks uniting the superior and middle cervical ganglia, and appear to be direct upward continuations of the trunks into the carotid canals. A more significant feature is the occasional finding of macroscopic ganglia on these nerves, and the constant occurrence of discrete, microscopic collections of ganglion cells within them. These facts, and the morphological position of these nerves ventral to the costal vertebral elements, suggest that they are not purely branches of distribution of the superior cervical ganglia, but are cephalic continuations of the sympathetic trunks. The discrete collections of cells may represent the sympathetic trunk ganglia of the primitive head segments, which have become telescoped and fused in man in the chordal part of the skull base, although evidence of segmentation still persists in the myotomes, branchial arches and mode of innervation. If this conception is correct, the interconnexions between the internal carotid and various cranial nerves arise in part from cells within the former, and they are homologous with rami communicantes arising from other parts of the sympathetic trunks.

Attempts to determine the exact nature, origin and course of the fibres in the internal carotid nerves by histological methods produce equivocal results, because the calibre, staining reactions and degree of myelination are not absolute guides to their character, and attempts to trace fibres in serial sections through the ganglionic maze of axons and dendrites have so far been unsuccessful. For reasons given later, experimental attempts to discover the origin and course of the fibres are hedged around with unusual difficulties.

Theoretically, preganglionic fibres could reach the internal carotid ganglia either from the thoracolumbar or cranial autonomic outflows, the latter through known and unknown interconnexions with various cranial nerves. Or fibres from both sources could reach the ganglia, and then they would be mixed sympathetic and parasympathetic structures; this possibility should not be dismissed because it is novel or conflicts with current opinions. It is customary to repeat, for example, that the sympathetic outflow is entirely thoracolumbar and that all preganglionic sympathetic fibres for the head end travel upwards in the cervical sympathetic trunks. Although the argument will not be elaborated here, it is doubtful if either statement is correct. The sympathetic outflow is predominantly thoracolumbar, but smaller numbers of preganglionic fibres emerge through other spinal nerves, and some of these may reach the superior cervical or internal carotid ganglia via upper cervical rami communicantes. Moreover, there is little doubt that a proportion of the sympathetic fibres for the head end run in the vertebral and other paravascular nerves. Thus preganglionic fibres could reach the internal carotid ganglia through the sympathetic trunks, the upper cervical rami communicantes, in paravascular nerves (vertebral, ascending cervical and pharyngeal, etc.) or through interconnexions with various cranial nerves.

Bearing all these potential routes in mind, it is practically impossible to devise experimental procedures to eliminate every alternative and provide adequate controls, and many mistakes have been made because of the failure to appreciate the existence of the less obvious pathways mentioned. Unilateral section of the sympathetic trunk below the superior cervical ganglion, with subsequent comparison after an appropriate interval of the internal carotid nerves of both sides, will not prove conclusively whether preganglionic fibres pass into these nerves: such fibres reaching the superior cervical or internal carotid ganglia through other channels would persist unchanged after the experimental trunk section and would vitiate the results. However, the gradual diminution in size of the internal carotid nerves from below upwards does indicate that the majority of the fibres are flowing in a cephalic direction from the sympathetic outflow.

By analogy, one other feature lends support to the view that the internal carotid nerves are cephalic portions of the sympathetic trunks. A ganglion (of Ribes) has been described alongside the anterior communicating artery, and it is known that filaments from the opposite internal carotid nerves extend along this vessel. One has found only microscopic collections of ganglion cells in this situation in man, but a macroscopic nodule was detected in one rhesus monkey and was proved histologically to be a ganglion. Perhaps the rostral extremities of the sympathetic trunks coalesce in this region, the site of union being indicated by a cranial ganglion impar. The resemblance of this to the caudal arrangement of the sympathetic trunks needs no emphasis.

To summarize: the true rostral extremities of the sympathetic trunks may unite around the anterior communicating artery in a cranial ganglion impar, and the internal carotid nerves, with their discrete groups of ganglion cells, may be the cephalic portions of the sympathetic trunks and not merely branches of distribution of the superior cervical ganglia.

The expenses of this investigation were defrayed with the aid of a grant from the Nuffield Foundation.

The Terms Homothallism and Heterothallism

F. L. Drayton and J. W. Groves have recently[1] presented a scholarly and eloquent plea for a return to the original definitions of the terms homo- and heterothallism as proposed by A. F. Blakeslee[2]. When their arguments are carried to their logical conclusion, the authors are forced to admit: "It is undoubtedly true that the fungus that originally suggested the idea to Blakeslee is not heterothallic in the sense in which he defined the term". I contend that an error in logic has escaped these authors in allowing them to arrive at such a conclusion.

Blakeslee wrote[2]: "According to their method of zygospore formation, the various species among the Mucorineae may be divided into two main categories, which may be designated as *homothallic* and *heterothallic*, and which correspond respectively to monoecious and dioecious forms among the higher plants". In his later attempts to homologize the mating reactions which he observed with sex in the higher plants, Blakeslee merely obscured what was, originally, a rather neat distinction. Monoecism and dioecism are, unquestionably, morphological terms, not physiological ones. The facts, however, are irrefutable: Blakeslee saw a physiological phenomenon, which he believed to be the analogue of the morphological phenomenon, sex, in higher plants. The terms homo- and heterothallism were coined to describe this physiological phenomenon, not a morphological one. To imply that the mucors do not fit the original definition taxes logic.

Two years later, Blakeslee[3] had already extended his definitions, in an attempt to further the homology of his mating types and 'sex'. It is in an attempt to follow this extension of the original definitions that, in my opinion, Drayton and Groves have gone astray.

Indeed, without differentiated male and female sex organs, Blakeslee could scarcely have made a definition on the basis of morphology, as Drayton and Groves would have one to believe.

The separation of morphological sex organs on separate plants (diœcism) is indeed, as stated by Drayton and Groves, "a phenomenon of fundamental biological importance". This is one means of ensuring cross-fertilization, as opposed to selfing. It is by no means the sole method of ensuring this result which Nature has evolved. Sterility factors, in particular, seem to have arisen in all groups in which the problem has been investigated. The various mechanisms are, in total, of even greater "fundamental biological importance".

As the terms homo- and heterothallism are used in the current mycological literature, they embrace that total concept. A homothallic fungus is one in which the sexual cycle can be completed starting from a single haploid nucleus; a heterothallic fungus is one in which the sexual cycle can only be completed by the union of two, physiologically different, haploid nuclei. Referring to Blakeslee's original paper[2], in the two paragraphs immediately following his definition are statements concerning whether zygospores can or cannot be obtained from a "single spore". The present concept differs from Blakeslee's only in that it substitutes the more precise term "haploid nucleus" for "single spore".

Unfortunately, homo- and heterothallic have been somewhat pre-empted by botanists for use as morphological terms. *Marchantia polymorpha*, for example, is often referred to as heterothallic rather than diœcious. Purists have objected to using monœcism and diœcism for both gametophyte and sporophyte generations, and Blakeslee's terms have been welcomed for such groups as the mosses and liverworts, where they are used in a morphological sense. Mycologists, however, have generally held to the physiological definition originally propounded by Blakeslee.

What would be the results if one were to follow Drayton and Groves, and certain botanists, and were to interpret homo- and heterothallism as morphological terms? With very few exceptions, the fungi would be universally homothallic; for example, all Basidiomycetes, including the rusts and smuts, nearly all Ascomycetes, including all the usual genetic tools, etc. The fundamentally significant biological (genetical) principle—the development of outbreeding mechanisms—would be obscured and would occur in two groups: a very few 'true' heterothallic (= diœcious) forms, and 'self-sterile homothallic forms. The vast and growing literature of microbial genetics would be filled with a misuse of the terms; and Blakeslee's classical mucors would have to be taught as homothallic (self-sterile) rather than as heterothallic.

What are the results if one adheres to established usage (and, I believe, to Blakeslee's original definitions) and interprets the terms as physiological ones? For the exceedingly few cases in the fungi in which male and female sex organs are differentiated and borne on separate thalli, a modifying word will have to be added: these fungi are diœcious as well as heterothallic. Examples are *Stromatinia narcissi*, special strains of *'Hypomyces' solani* f. *cucurbitae*, certain Laboulbeniales, and some water moulds. Nearly all the remaining heterothallic forms are monœcious. Whitehouse's[4] corresponding "morphological heterothallism" and "physiological heterothallism" are unnecessary in that all heterothallism is essentially physiological, and the morphological concept is better expressed with a morphological term, here diœcious or monœcious.

The purist objecting to monœcious and diœcious in gametophytes may prefer the alternative transliteration, monoicous and dioicous, now taking hold in the bryophyte literature, or could use Whitehouse's[4] haplo-monœcious and haplo-diœcious. Blakeslee's[3] terms homo- and heterophytic, offered as equivalents in the sporophyte of the terms monœcious and diœcious, have not come into general use but are available if needed. In my opinion, the terms homo- and heterothallic should be left for the mycologists' use in discussing the type of physiological phenomenon which Blakeslee observed.

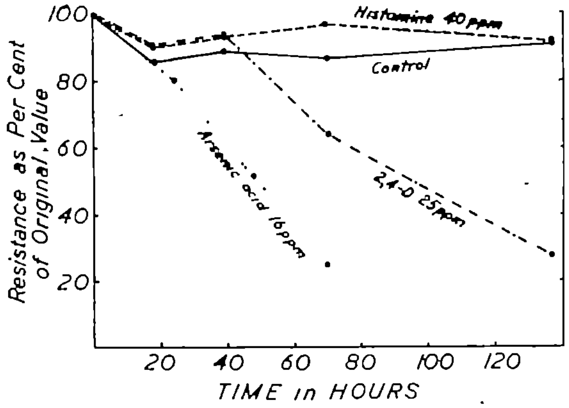
Phytotoxicity of Histamine, Arsenic Acid, and Dichlorophenoxyacetic Acid, and Methods of Testing

The recent paper by Allen and Skoog[1] on the phytotoxicity of imidazoline derivatives prompts this report on tests which have been made with the related β-imidazolyl-4-ethylamine (histamine). Some comments are added concerning the suitability of methods for measuring toxicity.

Tests were made with histamine because it is liberated in wounded animal tissues, is highly toxic to them, has been recorded as occurring in plant tissues[2], and because a phytotoxic substance is liberated when some plant tissues are macerated[3]. Tests were also made with 2,4-dichlorophenoxyacetic acid and arsenic acid to give a basis for comparison.

Tests with the method described below confirmed that the undiluted sap extracted from potato tubers was highly toxic to disks of such tubers. A chemical test also confirmed the presence of a substance reacting like histamine in the extracted sap, obtained from tubers macerated in a Waring blender. For this test, the conditions of diazotization recommended by Havinga *et al.*[4] were used. The procedure for preparing the sample to be diazotized was based on the methods devised by Koessler and Hanke[5], namely, add 2 vol. ethanol, adjust to pH 4, filter, chill overnight, filter, evaporate to original volume under reduced pressure, filter, add sodium hydroxide to 20 per cent concentration, filter, extract with amyl alcohol, extract with hydrochloric acid, evaporate to dryness on a water bath, dissolve in water and filter, add sodium hydroxide as before and repeat process to final filtration, then diazotize. The colour obtained indicated the equivalent of approximately 1 μgm. of histamine dihydrochloride per ml. of original sap macerate.

For testing toxicity, disks of potato tuber 19 mm. diam. × 1 mm. thick were used. After being cut, they were washed for five hours in an aerated isosmotic solution of sea salt (approx. N/10) and then transferred to 300 ml. of fresh salt solution to which the histamine or other substance had been added.



Graph showing effects of certain substances on the electrical resistance of slices of potato tuber (16 p.p.m. H_3AsO_4, 25 p.p.m. dichlorophenoxyacetic acid and 20 p.p.m histamine (dihydrochloride) are equimolar)

The solutions were constantly aerated and kept at 24° C., and toxicity was determined by the fall in resistance of the disk, determined between two electrodes at 1,000 c./s.[6] (the more potent the poison the more rapid is the fall in resistance). The disks were handled with forceps and rubber gloves.

As 1 p.p.m. and 5 p.p.m. of histamine dihydrochloride and 10 p.p.m. of dichlorophenoxyacetic acid had little if any effect on potato disks over a period of a few days, tests were made at higher concentration. The accompanying graph shows some results obtained, each point in the figure representing the mean value for two disks. For clarity the results with 20 p.p.m. of histamine dihydrochloride have been omitted, as they are similar to those obtained with 40 p.p.m., even to the rise at the 70-hr. measurement. It will be seen that at 20 and 40 p.p.m. histamine dihydrochloride has negligible if any toxic action. Accordingly, it is unlikely that histamine or histamine alone is the phytotoxic principle in expressed potato sap. In its negligible response to histamine, the central tissue of potato tubers differs from some animal tissues. In its negligible phytotoxicity histamine appears to resemble some of the imidazoline compounds with small substituted side-groups[1]; however, it must be remembered that these imidazoline compounds were tested by other methods.

The above method is a method for testing local toxicity, and shows that arsenic acid has greater local toxicity to potato tubers than dichlorophenoxyacetic acid. Arsenic acid also has greater remote toxicity than dichlorophenoxyacetic acid to mature roots of skeleton weed[7]. However, tests on young bean plants (growth-regulating tests) do not give similar results for remote toxicity, as shown by the following experiment made according to the general technique of Lucas and Hamner[8].

0·023 ml. of 0·1 per cent dichlorophenoxyacetic acid at *p*H 3·0, applied to one primary leaf per bean plant, reduced bud weight by more than 50 per cent (in eight days). On the other hand, 0·023 ml. of 1·0 per cent arsenic acid similarly applied had no effect whatever on bud weight, although one-third of each of the treated leaves was killed. The failure of this experiment to demonstrate the remote toxicity of arsenic acid is not necessarily attributable to the rapid death of tissues in the neighbourhood of the area of application. With skeleton weed it has often been possible to kill the roots to a depth of 18 in. or more by the application of 5–7½ per cent arsenic acid to the leaves, even though the leaves were discoloured and dead within 18 hours.

Certain tests for toxicity were recently reviewed by Blackman[9], who pointed out that techniques utilizing depression in growth or percentage mortality after spray application have the advantage that they are equally suitable for estimating the toxicity of compounds which do not come within the category of growth regulators. Nevertheless, the above electrical method should be considered eminently suitable for determining the local toxicity of poisons to mature tissues which are capable of little growth, which may be obtained in the form of thin slices, and in which death is not readily determined by visual observation. With micro-electrodes it is possible to work on smaller slices. Moreover, the method has the advantage that it may be used on root tissues as well as on stem tissues; this may be important, because root tissues do not necessarily respond to auxins and poisons in the same way as stem tissues. The saline solution can be buffered or otherwise modified.

Tests for remote toxicity to roots of perennials are at present difficult and laborious. Since remote toxicity depends on both effectiveness of translocation and on local toxicity, the above electrical method should be useful in screening tests of likely poisons for the roots of perennial plants. At present most screening tests are done on comparatively young tissues. However, it must be recognized that poisons will not necessarily behave similarly on young tissues and on mature tissues such as the roots of perennials.

Further work is being done on the identity of the toxic principle liberated on macerating plant tissues.

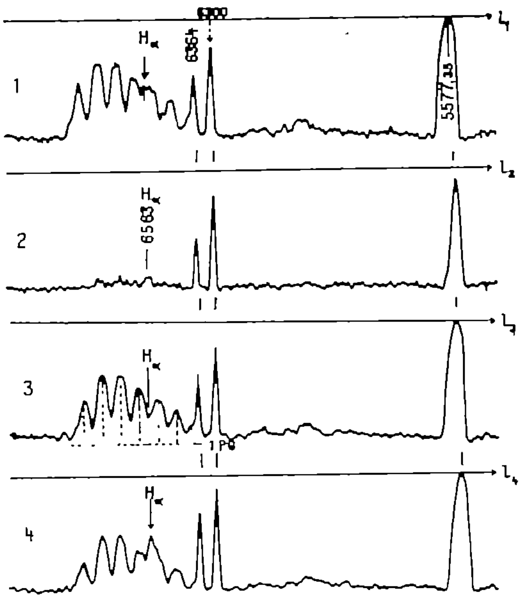
Great Intensity Variations of H_α and Effects in Auroral Spectrograms taken in Rapid Succession

BY means of a new spectrograph, constructed by J. Cojan at the Société Générale d'Optique, Paris combining the high light power $F : 0{\cdot}65$ with a fairly good dispersion, four spectrograms were taken at the Auroral Observatory, Tromsoe, on December 3, 1951 at about 23h. 00m. The spectrograms were taken on Kodak 103*a*-*T* plates and in rapid succession on the same plate with times of exposures from 4 to 10 min.

Photometer curves of the four spectrograms in the long-wave region from the green line towards the red part are shown herewith, in which the horizontal lines l_1, l_2, l_3, l_4 indicate the zero position of the registering galvanometer corresponding to an opaque plate. We notice that, in spite of the short exposures



the green line is greatly over-exposed, except in spectrogram (2). In addition to the green line, we notice the red O I doublet (6300, 6364), the H_α-line, and bands belonging to the first positive group of nitrogen (indicated by 1.P.G. on curve 3).

The great variations in the intensity distribution of these lines and bands must be co-ordinated with the way in which the exposures were made.

Spectrogram 1. Exposure 4 min. towards a band with ray structure appearing near the horizon towards the south and south-east.

Spectrogram 2. Exposure 5 min. towards auroral ray structures near the zenith.

Spectrogram 3. Exposure 7 min. on a homogeneous arc of moderate intensity towards the north.

Spectrogram 4. Exposure 10 min. towards auroral rays, where they appeared with the greatest intensity.

As spectrogram (2) mainly corresponds to auroral rays of great altitudes, and (3) to the low altitude of about 100 km. of an ordinary arc, they give a brilliant illustration of the two following well-known altitude effects: (*a*) enhancement of the red O I doublet with increasing altitude; (*b*) enhancement of the red bands of the first positive group of nitrogen towards smaller altitudes; this effect explains the red lower border sometimes observed on auroral arcs (red aurora of type *B*).

While H_α appears with considerable intensity on spectrograms (1) and (4), it is just noticeable on (2) and absent on (3). This great variability of the intensity of H_α can be explained in a simple way on the views I have proposed (for example, refs. 1, 3, 4, 8), that the auroras and magnetic disturbances are produced by solar electric ray-bundles composed of rays of electrons electrostatically neutralized by positive ions, preferably protons.

The correctness of this view was shown during 1939–40, when it was seen[8-10] that hydrogen lines occasionally appeared in the auroral luminescence and showed a Doppler effect corresponding to velocities of the protons towards the earth of the order of 1,000 km./sec. The Doppler effect of auroral H-lines has also recently been studied by Gartlein[11] and by Meinel[12].

As shown in previous papers[4,7,8], a bundle composed of protons and electrons has the following properties: the electric current density i is equal to $ne(V_e - V_p)$, where V_e and V_p are the velocities of the electrons and protons respectively, n is number of electrons and protons per unit volume. The number of protons entering the atmosphere in unit time relative to that of the electrons is equal to V_p/V_e, and the great variability of the intensity of the H-lines in the auroral luminescence is thus first of all due to a change of the relative proton velocity.

With increase of proton velocity, however, the magnetic stiffness of the bundle increases and consequently the distance of the aurora from the magnetic axis increases. This may explain why H_α appears strong on spectrogram (1), which corresponds to an aurora with ray-structure low down on the southern sky.

For the H-lines to be emitted the protons must be neutralized. At great altitudes the neutralized fraction is very small, but increases downwards. Further, if the energy of the protons is not greater than that of the electrons, the protons will be stopped at a considerably higher level than the electrons. In this way we explain the small intensity of H_α on spectrogram (2), which may correspond to an altitude so great that only a small fraction of protons is neutralized.

The absence of H_α from spectrogram (3) may result from two causes. The appearance of the arc on the northern sky indicates a small relative proton flux in the solar bundle. Small proton flux means small relative velocity and penetrating power of the protons. Consequently, they may be stopped before reaching to the lower part of the arc, from which the light through the slit has been emitted.

Spectrogram (4), showing a strong H_α-line, may correspond to altitudes where a considerable fraction of the protons is neutralized and not absorbed.

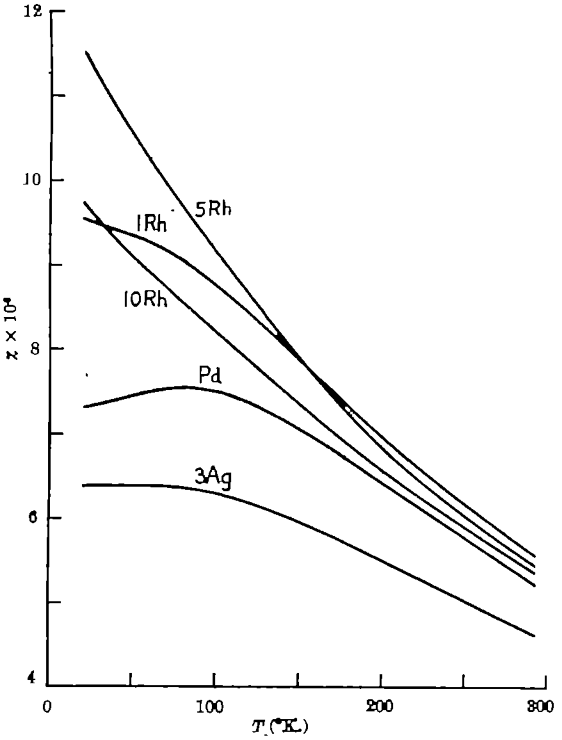
Magnetic Susceptibilities of Palladium–Rhodium Alloys from 20° to 300° K.

THE rapid, yet accurate, method of measurement and the results thereby obtained for the magnetic susceptibilities of platinum, rhodium and palladium between liquid hydrogen and room temperatures have been previously described by two of us[1]. The same measurement techniques were afterwards applied to a series of polycrystalline palladium-silver alloys; the specific heats of these alloys have also been investigated (both sets of results yet unpublished). The results, when interpreted through the collective electron theory, make possible an estimate of the size and shape of the normally unfilled portion of the d electronic energy-band of metallic palladium, on the assumption that the addition of small amounts of silver to palladium causes a reduction of the number of holes in the d-band without significantly modifying its shape. With the filling of the band, it would be expected that the magnetic susceptibility and its variation with temperature would be affected. It was actually found experimentally that both decreased monotonically with increased silver content.

It therefore became of interest to explore the possibilities of increasing the number of holes in the d-band by alloying small amounts of an appropriate metal with palladium, and to study the resultant effects on the magnetic susceptibility. Rhodium (atomic number 45), with one less electron per atom than palladium (atomic number 46), in contrast to silver (atomic number 47) with one more, appeared to be an obvious element to choose for this purpose. Moreover, the similarity in the size of the atoms of palladium and rhodium would favour extended solid metallic solubility; hence, although a phase diagram for palladium–rhodium alloys is not available at present, we can be fairly confident that at least over a small range of palladium-rich compositions there are no complicating phase changes.

We have now investigated the paramagnetic susceptibilities of a number of spectrographically pure palladium–rhodium polycrystalline specimens from room temperature down to that of liquid hydrogen, by the experimental method referred to above. The results for the three specimens (1, 5 and 10 per cent rhodium) that have been studied to date are presented in the accompanying graph along with those previously obtained for pure palladium and a 3 per cent silver palladium–silver alloy. Each curve represents approximately ninety experimental points evenly distributed over the entire temperature-range. The mean deviation of the points from the corresponding curve is about 0·2 per cent of the susceptibility. The substantial increase of the low-temperature susceptibilities, which accompanied the additions of rhodium up to the 5 per cent rhodium alloy, gives some support to the general type of interpretation suggested for the palladium–silver alloys. It is not surprising, however, to find that, for a further increase in rhodium content, the magnetic susceptibility began to decrease, the paramagnetic susceptibility of pure rhodium being only about 10^{-6} over the entire temperature-range in question. Undoubtedly, the dependence of the experimental susceptibility versus temperature curves on the composition of these alloys will provide valuable material for the elucidation of the electronic structure. At present, however, we merely present our initial experimental results. We are continuing our study of this and other related alloy series and will report more fully later.



Gram-susceptibility versus absolute temperature of pure palladium (Pd) of palladium–rhodium alloys of 1, 5 and 10 atomic per cent rhodium (1 Rh, 5 Rh, 10 Rh), and of a palladium–silver alloy of 3 atomic per cent silver (3 Ag)

Acid Salts of Monobasic Organic Acids: a New Series of Primary Standards for Alkalimetry

It has long been known[1-3] that most monobasic acids HX are capable, in suitable circumstances, of combining with their metallic salts MX to form 'acid salts'; for example, of the type $(MX)_m(\mathrm{H}X)_n$.

The potassium compounds of this type derived from organic acids frequently have the stoichiometric composition of 1 mole acid : 1 mole salt, and are easily obtained and purified. Certain of these substances would probably prove highly suitable as primary standards in volumetric analysis; their use in the preparation of buffer solutions has already been noted[2,3]. In particular, the use of a new compound, potassium hydrogen *bis*-3 : 5-dinitrobenzoate (no definite melting-point, but explodes on strong heating), is proposed (found: K = 8·56, 8·58 per cent; equivalent weight = 461·7, 463 0; calculated for $C_{14}H_7O_{12}N_4K$, K = 8·46 per cent; equivalent weight = 462·3).

This substance is easily obtained by dissolving 21·2 gm. of 3 : 5-dinitrobenzoic acid (B.D.H.) (2 equiv.) in 60 ml. of acetone and adding a solution of 3·5 gm. A/R potassium carbonate (1 equiv.) in 20 ml. hot water. On cooling, small needles separate, and may be recrystallized from a 3 : 1 acetone–water mixture without alteration. After drying in a vacuum desiccator, the substance is non-hygroscopic, stable in air, and a sample has been kept for more than six years without a detectable change. As the dissociation constant of 3 : 5-dinitrobenzoic acid is $1 \cdot 57 \times 10^{-3}$ at 25° [4], a suitable indicator for its titration with 0·1 N sodium hydroxide is thymol blue (alkaline range). The solubility of 3 : 5-dinitrobenzoic acid in water is rather low (0·00635 mole per litre at 25° [5]) and the potassium hydrogen salt is only slightly more soluble than this, being decomposed by water into the free acid and a solution of the potassium salt together with a little of the acid.

No organic compounds of this type have been proposed previously as alkalimetric standards. Potassium bi-iodate, already in use for alkalimetry and iodimetry[4], is a similar acid salt of an inorganic monobasic acid. Alkali metal hydrogen salts of organic dibasic acids already used as standards suffer from several disadvantages not possessed by the substance now advocated. For example, potassium hydrogen phthalate must be recrystallized from water above 35° [7]; potassium tetroxalate must be kept under conditions of definite vapour pressure[8]; potassium hydrogen oxalate cannot be recrystallized from water without change[9]; potassium hydrogen tartrate has a low solubility in water and is difficult to obtain pure[10].

This investigation is being continued, and will be discussed in greater detail elsewhere.

Thermal Transformations of the Aluminas and their Hydrates

SEVERAL polymorphic forms of anhydrous alumina derived from the calcination of hydrated aluminas have been described by various authors[1-3]. The interpretations made of the relationships which exist between the hydrated and anhydrous forms presuppose that the dehydration of gibbsite and bayerite occur through bohmite, and that the dehydration of the bohmite derived from gibbsite can unaccountably yield one of two series of transformations before α-alumina is finally produced.

Work which we have carried out over a number of years and which will be published elsewhere has led us to believe that the böhmite which is encountered in the dehydration of both gibbsite and bayerite is produced by secondary reactions between the original dehydration products, which are virtually anhydrous aluminas, and the water which is released during the reaction, and our conclusions are illustrated in the accompanying diagram.

Bayerite gives rise on calcination to γ-alumina which is capable only of hydration to bohmite. Böhmite also yields only γ-alumina, so both these hydrates give rise to the γ—δ—θ [2] forms of anhydrous alumina.

Gibbsite, on the other hand, yields initially another form of alumina. This anhydrous alumina has a crystal form for which the lattice spacings of the two most intense lines have d values 2·11 and 1·39, the latter being identical with that of one of the major lines of γ-alumina. It is convenient to label this χ-alumina, and we have found that this is, in fact, only one of the components of the $(\gamma + \chi)$ mixture derived from gibbsite which had previously been designated χ [3]. True χ-alumina is capable of hydration to bayerite at temperatures below 140°, and above 140° to böhmite, and on further calcination yields true κ-alumina before final conversion to α. In practice, therefore, we find on dehydrating gibbsite a mixture of χ-alumina and böhmite, the latter being derived from the secondary reaction of χ with water. Subsequent calcination at higher temperatures therefore gives rise to mixtures of the two series of anhydrous forms, that is, γ—δ—θ—α, associated with the bohmite component, and χ—κ—α associated with the original dehydration product χ.

IDEALIZED ALUMINA-WATER SYSTEM

Chromatography of Rubber Accelerators and Anti-Oxidants on Silica Gel

THE chromatographic separation on alumina columns of certain constituents from the acetone extracts of vulcanized rubbers has been reported by Bellamy and co-workers[1] and by Mann[2]. As an adsorbent for such materials, alumina suffers from certain disadvantages, in particular, its tendency to favour chemical change in labile adsorbates. The successful use of silica gel/'Celite' for the chromatographic separation of a variety of ingredients from propellants and high explosives[3,4] suggested that this adsorbent might prove equally useful for the separation of the ingredients of vulcanized rubbers, and this has, in fact, been borne out by recent work in this laboratory. The procedure adopted for the qualitative examination of a rubber extract is as follows. A number of separate portions of the extract (each equivalent to 0·2–0·4 gm. of the rubber) are chromatographed on 1-cm. diameter columns using a series of different binary solvent mixtures as developers. When the extruded columns have been streaked with appropriate reagents, the positions of the zones, together with the colours of the streaks, give a reason-

Compound	Streak reagent	Developing solvents
Diphenylguanidine	30 per cent w/v Sodium hypochlorite solution	25 ml. of 20 per cent ethyl alcohol in light petroleum
Triphenylguanidine		
Thiocarbanilide		25 ml. of 1·5 per cent ethyl acetate in benzene
Tetramethylthiuram monosulphide	5 per cent w/v Aqueous $CuSO_4.5H_2O$	
Tetramethylthiuram disulphide		
Mercaptobenzthiazole (MBT)	5 per cent w/v $Bi(NO_3)_3$ in 0·5 N nitric acid	
Tetra ethylthiuram disulphide	5 per cent w/v Aqueous $CuSO_4.5H_2O$	25 ml. of 2 per cent ethyl acetate in carbon tetrachloride
Dibenzthiazolyl 2-disulphide (MBTS)	5 per cent w/v $SnCl_2.2H_2O$ in 2·5 N hydrochloric acid followed by 5 N sodium acetate followed by 5 per cent w/v $Bi(NO_3)_3$ in 0·5 N nitric acid	25 ml. of benzene
2-Benzthiazolyl N′-cyclohexyl sulphenamide		
Phenyl β-naphthylamine	1 per cent w/v $(NH_4)VO_3$ in 60 per cent sulphuric acid	25 ml. of 1 per cent ethyl ether in light petroleum
Phenyl α-naphthylamine		

ably unambiguous identification, which can be further confirmed by ultra-violet absorption measurements.

Using this method, it is possible to distinguish between the compounds named in the table even when present in admixture with one another and with other normal compounding ingredients, including pine tar. In most cases quantities as small as 0·05 mgm. can be detected on a column of 1 cm. diameter.

The same developers can be used for the detection of other accelerators and anti-oxidants, although complete separation from all other compounds cannot always be attained with a single chromatographic treatment. Thus it has been possible to detect *m*-toluylene diamine, *sym*-diphenyl-*p*-phenylene diamine, *sym*-dinaphthyl-*p*-phenylene diamine and some complex commercial materials containing, for example, aldehyde-amine condensation products or polymerized dihydroquinoline derivatives. The separation of more closely related compounds can also be attained. For example, derivatives of dimethyl-, diethyl- and dibutyl-dithiocarbamates can readily be distinguished from one another by chromatographing the brown copper complexes.

With minor modification, some of the methods can be adapted for quantitative determination. Good recovery of adsorbates has been obtained with the particular silica gel adsorbent in use. In this connexion, Bloomfield[5] has suggested that alumina may cause decomposition of labile accelerators during chromatography, and that such products may be mistaken for transformation products of the accelerator produced during the vulcanization process. Mann[2] has, in fact, observed the decomposition of dibenzthiazolyl 2-disulphide to mercaptobenzthiazole on alumina columns. In contrast, I have found that dibenzthiazolyl 2-disulphide can be chromatographed unchanged on our silica gel columns. Nevertheless, I have identified both mercaptobenzthiazole and dibenzthiazolyl 2-disulphide in the extracts of rubbers accelerated with either; this is in agreement with the findings of Dufraisse and Houpillart[6]. I have also observed mercaptobenzthiazole in the extract of a rubber accelerated with 2-benzthiazolyl N′-cyclohexyl sulphenamide. However, considerable care is required in the interpretation of the chromatograms, as there is evidence that labile accelerators can undergo further transformation during the process of acetone extraction of the rubber.

This investigation is continuing and will be reported in detail elsewhere.

Translocation of Iron in Podzol Formation

SEVERAL mechanisms have been postulated to account for the translocation of iron and aluminium in the process of podzol formation. Thus Jones and Willcox[1] suggest that simple organic acids such as oxalic acid are responsible for the solution of the sesquioxides, while numerous workers[2] consider that the free oxides are peptized by the action of humus and move as sols.

It has been found in this laboratory that water extracts of the undecomposed leaves and bark of the New Zealand kauri (*Agathis australis*) and of Scots pine needles (*Pinus sylvestris*) are capable of causing rapid reduction of soluble ferric compounds to the extent of some 4–5 mgm. of iron per gram of air-dry Scots pine needles. Furthermore, over a wide range of *p*H values (4–7), the extracts are capable of causing non-biological solution of relatively large amounts of hydrous ferric and aluminium oxides. Ferrous iron, as determined by *αα*′-dipyridyl, accounts only for a part of the dissolved iron; but as the extracts are still capable of reducing considerably more iron than has already been dissolved, it is unlikely that the difference between the total and the dipyridyl-reactive iron represents iron in the ferric state. Experiments on the effect of the plant extracts on the recovery of ferrous iron by dipyridyl from solutions of ferrous sulphate show that complexing of the ferrous iron is, in part at least, the cause of the discrepancy between the total and the dipyridyl-reactive iron. It therefore seems probable that the whole of the dissolved ferric oxide is reduced to the ferrous state. Continuous aeration of the reaction mixture appears to have little or no effect on the solution and reduction of ferric oxide. These results resemble very closely those previously obtained with anaerobically fermented grass[3].

It can be seen from these results that the percolation of rainwater through undecomposed coniferous litter provides all the necessary conditions for the leaching of sesquioxides from the surface layers of the soil. In view of the capacity of the aqueous extracts for reducing ferric iron, it seems most probable that translocation of the iron takes place in the form of a ferrous organic complex.

Relief of Hypoglycæmic Convulsions with Butyric Acid

THE lower volatile acids, acetic, propionic and utyric, have been widely studied in relation to termediary metabolism[1,2]. Propionic acid is known o be glucogenic, and sodium propionate has been ound to relieve severe hypoglycæmic symptoms in n adrenalectomized ewe; but sodium acetate was ithout effect[3]. Butyric acid has usually been studied n relation to the metabolism of fat and the pro-uction of ketone bodies[4]; but there are some uggestions that it may also be implicated in carbo-ydrate metabolism[5]. Moreover, Jarrett, Potter and ilsell[6] have found that the concentration of blood ugar and of pyruvic acid was increased after sodium utyrate had been injected into the blood-stream of heep.

In view of the possible association of the meta-olism of butyric acid with that of carbohydrate, the ffect of sodium butyrate administration on an nimal in convulsions was studied.

Eight young merino lambs aged between 1 and 8 days were fasted for 24 hr. and then given an travenous injection of insulin in the manner em-loyed by Comline *et al.*[7]. The subsequent hypo-lycæmic convulsions were found to be relieved by n intrajugular injection of 10 ml. sodium butyrate, ontaining 2·5 m*M* butyric acid/kgm. neutralized o *p*H 7·0 with sodium hydroxide. Sodium propionate 2·5 m*M* propionic acid/kgm.) had a similar effect, ut there was no response to sodium acetate (2·5 m*M* cetic acid/kgm.).

Convulsions which supervened in two adult ewes n which the splanchnic nerves had been sectioned[8] ere similarly relieved by 30 ml. of either butyrate r propionate but not by acetate.

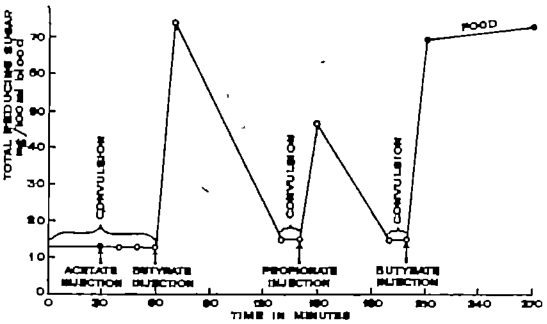
Insulin-induced hypoglycæmic convulsions in rab-its were also relieved by 5 ml. of intravenous sodium utyrate (2·5 m*M* butyric acid/kgm.) and by pro-ionate but not by acetate.

Total reducing sugar in the blood[9] estimated in amples taken prior to the insulin injection, during onvulsion, and ten minutes after the injection of e volatile acids, showed that the relief of the con-ulsions was accompanied by a considerable rise in lood sugar.

Convulsions in lambs ceased immediately after he injection of butyrate: the coma which super-ened for 1–2 min. gradually subsided and within -10 min. the animals had regained their feet. An pparently normal state was maintained for about 0–40 min.: the animals then became lethargic and fter 50–60 min. again convulsed. This second onvulsion could be relieved with butyrate and if, n recovery, the animals were allowed to suck from eir dams no further convulsions ensued.

Butyrate, when administered to the adult ewes, owever, relieved hypoglycæmic convulsions but with ss spectacular effect. Acetate was found to be effective and propionate gave no more relief than utyrate.

Rabbits were observed to respond to butyrate jection in much the same manner as lambs and wes. On some occasions the coma that followed the jection persisted for as long as 20 min., after which e animals recovered rapidly and began to eat if lowed access to food. If prevented from feeding, ey became convulsed again 60–90 min. later, and nder these conditions were relieved by another jection of butyrate. Acetate was again ineffective and propionate did not relieve the symptoms as effectively in the rabbits as in the lambs and sheep.



Blood sugar curves of lamb *F* (aged 28 days) after sodium acetate, propionate or butyrate (2·5 m*M*/kgm.)

The concentration of sugar in the bloods of the lambs was raised from the low level of 10–15 mgm./100 ml. to which it fell during the convulsions, to 50–80 mgm./100 ml. ten minutes after the injection of butyrate. Injection of propionate led to a rise of only 30–40 mgm./100 ml., while acetate produced no alteration in the blood-sugar level (see graph).

Similar results were obtained with adult sheep and rabbits: the butyrate in all cases led to a greater increase in blood sugar than the propionate. The sugar in the blood of rabbits, however, was not increased as much as that of the lambs and sheep, but it remained elevated for a longer period.

Sodium propionate is known to be glucogenic and therefore might be expected to relieve hypoglycæmic convulsions: the greater efficiency with which sodium butyrate can also relieve them suggests that butyric acid may readily be converted to glucose *in vivo*. The mechanism of this conversion is obscure.

'Lipochondria' and the Golgi Substance in Epithelial Cells of the Epididymis

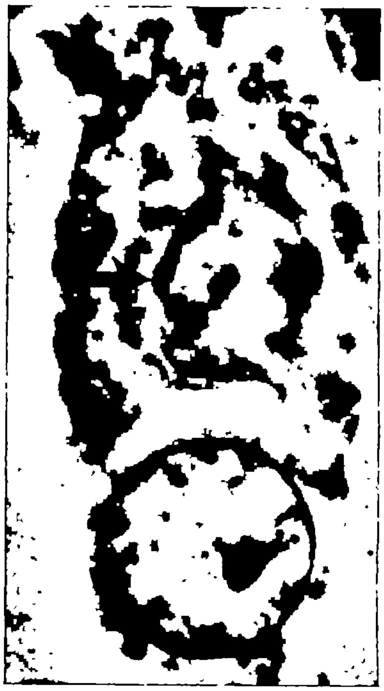
BOTH J. R. Baker[1] and O. L. Thomas[2] have expressed the view that 'lipochondria' (discrete sudanophilic droplets supravitally stainable with methylene blue and neutral red) are transformed into the classical Golgi network during the processes of fixation and impregnation with silver and osmic acid techniques. Thomas[2] also considers that mitochondria are involved in the development of the classical Golgi network during fixation.

In epithelial cells of the duodenum of the mouse we have not been able to demonstrate to our complete satisfaction that the droplets stainable supravitally with methylene blue and neutral red ('lipochondria'[1]) are identical with the substance stainable with sudan black in fixed material. The Golgi zone in this cell type is surrounded by numerous mitochondria as well as droplets of various size having different optical properties, so that for us it was impossible to determine accurately which bodies actually were within the Golgi zone and which were not. We decided, therefore, to turn to a study of the epithelial cells of the head of the epididymis of the mouse. These cells are relatively large compared with the epithelial cells of the duodenum and possess a large, clearly defined Golgi zone. Mitochondria and droplets are few in number in the immediate vicinity of the Golgi zone, and do not interfere noticeably with observations on this region of the cell.

We found that in this particular cell a classical Golgi network with filaments, lamellæ and vacuoles was strikingly demonstrable with phase contrast and less clearly but nevertheless definitely demonstrable with the ordinary light microscope in fresh unstained material. (A typical Golgi network may also be seen with phase contrast in some of the cells in fresh preparations of the seminal vesicles and ventral prostate gland of the mouse.) We also found that none of the substance of the Golgi zone stains supravitally with either methylene blue or neutral red. Droplets in the region between the nucleus and the Golgi zone took up these dyes avidly, but even after long intervals, when the nucleus became stained, there was still no evidence of staining within the Golgi zone. In fact, this zone was the one area of the cell which remained completely refractory to staining with these dyes. The strands of the network which appeared dark with the phase contrast and light microscopes stained diffusely with sudan black in fixed material. With the Kolatchev–Nassonov method these strands were impregnated with reduced osmic acid. Comparison of electron micrographs of positive and negative images of the Golgi material indicated that the substance responsible for the reduction of osmic acid (the osmiophilic component) is situated in the cytoplasm adjacent to the vacuoles and canals of the osmiophobic component. This suggests that the osmiophobic component represents the negative image of the Golgi substance frequently seen in routinely prepared and stained specimens, and that the osmiophilic component, being intimately associated with protein materials in the cytoplasm, does not contribute materially to this negative image.

Thus it may be stated that in this cell type the Golgi substance is clearly visible in the living cell as a definite network, classical in its form, which so far as we were able to determine is not modified by fixation with suitable fixatives. Further, it may be stated that in this instance the 'lipochrondria' of Baker have no structural or obvious chemical relationship to the Golgi substance, since by definition the 'lipochondria' are stainable supravitally with methylene blue and neutral red while the Golgi substance is not.

These results are comparable to those of O'Leary[4] who, following the lead of Bensley[5], demonstrated the negative image of the Golgi substance in living cells of the islets of Langerhans of the mouse ar determined that in this case also the Golgi substan was not stainable supravitally with either methyle blue or neutral red.



× 3,200

We would like to add that we are in agreement wi Baker[1] and Thomas[2] to the extent that, whenev feasible, living tissues should be studied experimen ally in preference to fixed tissues, and that, whenev possible, studies on fixed tissues should be suppl mented by studies on living cells. We feel justifi in pointing out at this juncture, however, that the are uncertainties inherent in conclusions drawn fro comparisons made between living and fixed ce when the size of the structures under investigatio in these cells are at the border line of, or beyond, t resolving power of the optical equipment used make the comparison. We cannot agree with eith Baker or Thomas that studies with the electr microscope have no place in the elucidation the enigma of the Golgi substance. Rathe we believe with Beams *et al.*[6] that every availab means of analysis should be used. The resul reported above and those reported previously[7] a to us adequate demonstrations of the usefulne of the electron microscope in this area investigation.

The results of this study will be reported in det elsewhere.

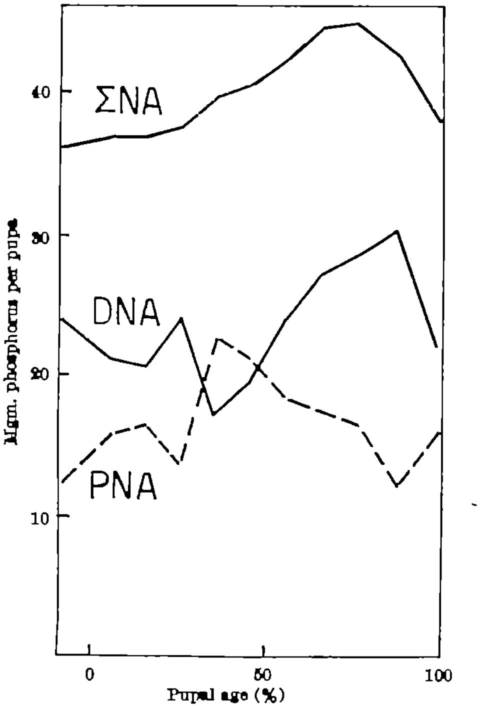
Nucleic Acid Metabolism during Insect Metamorphosis

THE transformation of the two nucleic acids, eoxyribonucleic acid and ribonucleic acid, one ito the other has been postulated by Brachet[1], sing developing sea urchin embryos as material for e investigation. Ribonucleic acid should be the recursor of deoxyribonucleic acid. These results ave been questioned by Villee *et al.*[2] and Abrams[3], mong others, who show that the amount of total ucleic acid phosphorus is not constant during deelopment. Further, with the aid of phosphorus-32 nd carbon-14 respectively, these investigators have emonstrated that the specific activity of deoxybonucleic acid is much higher, up to fifteen times, han of ribonucleic acid. These results indicate hat most of the deoxyribonucleic acid should rise from an endogenous precursor, which is not ibonucleic acid.

The insect pupa is a closed system in respect of ucleic acid metabolism. Moreover, metamorphosis characterized by a profound histolysis of the larval ssues and a corresponding histogenesis of the naginal organs. If there were any mutual interependence of the two nucleic acids, this would be een in such an organism. Therefore, investigations ere carried out on the fly *Calliphora erythrocephala* Meig.). As analytical method the phosphate fractiontion devised by Ogur and Rosen[4] was used. The hosphorus determinations were checked by spectrohotometric readings at 2500 A.

As is clear from the graph, there is an obvious nverse relationship between the amounts of deoxybonucleic acid and ribonucleic acid. Naturally his does not prove transformation from one acid o the other. However, it strongly suggests a mutual nterdependence of the two nucleic acids as regards heir synthesis.



Change in amount of deoxyribonucleic acid (*DNA*), ribonucleic acid (*PNA*) and total nucleic acids (*ΣNA*) during the metamorphosis period of *Calliphora*

There is an increase in total content of nucleic acid of about 25 per cent up to the point when histogenesis is almost finished. The phosphorus used seems to arise from the alcohol-soluble fraction. The final decrease is principally due to an increased decomposition of deoxyribonucleic acid during lysis of nuclei in the abdominal larval fat-body. The increase in amount of deoxyribonucleic acid during histogenesis is not only concerned with the growth of muscles in the thorax (cf. Agrell[5]). In the abdomen also there is an identical increase in deoxyribonucleic acid content, in spite of the fact that histogenesis processes are only very limited and consequently no increase in Feulgen-positive substance can be seen in this part of the body. It seems possible that deoxyribonucleic acid is synthesized in the cytoplasm of the abdominal fat-body cells in a form not detectable by the Feulgen reaction. The large cell granules of complex build could be the site of this process. The existence of cytoplasmic deoxyribonucleic acid has recently been shown to be probable by Zeuthen[6].

The inverse relationship in the amount of ribonucleic acid and deoxyribonucleic acid always shows the same course. However, the ratio of the two is remarkably different in different cultures of *Calliphora*; it varied from about 1·0 down to 0·4 in four experimental series of pupæ, all of which gave rise to normal imaginal flies.

Progesterone in Body Fluids

A METHOD has been developed for the assay of progesterone by which as little as 4 μgm. of the hormone can be detected. It is based on the technique of extraction and partition between organic solvents[1] and subsequent separation and semi-quantitative estimation by chromatographic partition on filter paper[2]. The method has been used for the detection and semi-quantitative determination of progesterone in biological material. The results are summarized as follows.

Blood withdrawn directly from the ovarian vein of ewes contained progesterone in concentrations ranging from 0·5 to 2 μgm. per ml. (see table). On the other hand, all attempts to detect progesterone in peripheral blood were consistently negative, both in pregnant and non-pregnant animals, in mare, cow, ewe and sow, although the quantities of blood used for analysis ranged from 10 to 160 ml.; the blood analysed came mostly from the jugular vein (mare, cow, ewe and sow), occasionally also from the middle uterine artery and vein (ewe). No progesterone could be detected in blood from the caudal vena cava of a female rabbit seven days after ovulation.

In cases where progesterone was detected in blood, the residue left after extraction of the hormone was analysed for 'bound' or conjugated progesterone[3].

PROGESTERONE IN BLOOD FROM THE OVARIAN VEIN OF EWES

Animals examined	Condition of ewe	Condition of ovary	Quantity of blood (ml.)	Progesterone found (μgm.)	Approximate concentration (μgm./ml.)
1	98 days pregnant	1 Corpus luteum	31	60	2
1	8 months pregnant	2 Corpora lutea	15	8	0·5
1	3½ months pregnant	1 Corpus luteum (left ovary) 2 Graafian follicles (right ovary)	35 41	55 40	1·6 1
1	8 days post œstrum	2 Corpora lutea	22	12	0·5
1	28 days post partum	Quiescent	40	nil	less than 0·1
5					

'Bound' progesterone did not exceed 15 per cent of the total. Blood samples in which no free progesterone was found gave consistently negative results when analysed for 'bound' progesterone.

The effect of intramuscular injections of progesterone on the level of progesterone in blood was studied on rabbits. Blood withdrawn from the caudal vena cava of a doe 25 min. after an injection of 25 mgm. pure hormone (in oil) showed a content of 0·2 μgm. per ml. No progesterone could be detected in rabbit blood 3 hr. and 8 hr. after injection.

Fluid obtained from Graafian follicles of a sow nearly at ovulation contained 8 μgm. progesterone per ml.

Cow's follicular fluid near ovulation contained 3 μgm./ml.; no progesterone was found in developing follicles, nor, three and four days after heat, in follicles which had failed to ovulate.

Fluid obtained from ovarian cysts of nine sows contained 1–5 μgm. progesterone per ml.

Luteal tissue from an elephant ovary, which had been preserved in formalin for 23 months, contained 2 μgm. progesterone per gram.

Cell Surface Constituents and Yeast Flocculation

THE cell wall of *Saccharomyces cerevisiae* holds nitrogen-containing complex polysaccharides. By a gradual extraction method I have obtained compounds which were homogeneous at sedimentation analysis and electrophoresis.

An aqueous suspension of fresh brewer's yeast was agitated with a laboratory stirrer for two hours at room temperature. A high-molecular mannan was thereby extracted, apparently being detached from the cell surface by friction. Analyses of the purified substance showed 1 per cent nitrogen and 0·2 per cent phosphorus. The molecular weight was calculated from sedimentation and diffusion measurements to be 340,000. The compound was of anodic migration in the *p*H range 3–10. At complete extraction 0·3 per cent was obtained from dry yeast. The substance was called 'cebrosan'.

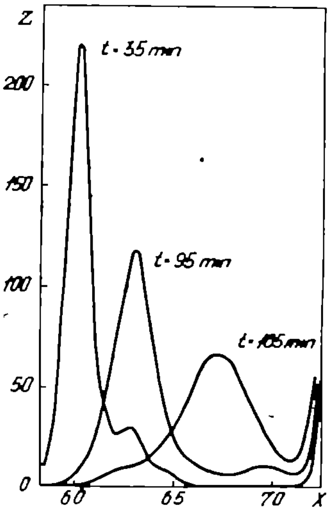
When the agitation was continued at a temperature of 30–45° C. a mucopolysaccharide with higher contents of nitrogen and phosphorus was extracted, of $s^0_{20} = 8 \cdot 1\ S$, and the isoelectric point 5·1. About 1 per cent from dry yeast was isolated. The substance was called 'mycetin'.

At subsequent high-speed agitation in a 'Turm blender about the same amount of yeast nucleic ac was extracted ($s^0_{20} = 2 \cdot 55\ S$). The preparatic were often accompanied by two high-molecular carl hydrates ($s_{20} \sim 13$ and $16\ S$, respectively) in mn quantities. No cell proteins were extracted by tl treatment.

When yeast of 25 per cent dryness was stor at 30–40° C. for two days, in the extracellu solution were found macromolecular carbohydrat in considerable amounts (6 per cent from d yeast), at nitrogen contents of 5–7 per cent up dry substance. Sedimentation analysis made evide four main compounds, of $s_{20} = 2 \cdot 8, 4 \cdot 0, 6 \cdot 5$ and $7 \cdot 2$ respectively, as well as a carbohydrate of bas properties, of $s^0_{20} = 3 \cdot 6\ S$. The latter was isolat by precipitation with alcoholic ammonia. It ga Ehrlich's reaction for glucosamine, and contain 5 per cent nitrogen. It was of cathodic migration the *p*H interval 4–11. A sedimentation diagra for the substance is given in the accompanyi illustration.

From top fermentation brewing yeast were obtain the same compounds as from bottom fermentati yeast. An essential difference was the extraction 1–2 per cent proteins on agitation of a top yea suspension at 30–45° C., which was not observ with bottom yeast.

Electrophoretical investigations upon isolated ce wall constituents made evident compounds of positi as well as negative charge. The flocculation mec anism is essentially explainable by the mutu attraction of oppositely charged groups on t surfaces of different cells, whereby large c



Sedimentation diagram for the basic compound extracted from the cell wall glomerations are rapidly modified. A coating ch proteins hinders the flocculation of top yeast, ess the pH of the medium is lower than their electric point, and favours adherence to carbon xide bubbles during fermentation, by which the ast rises.

The investigations were carried out at the titute of Physical Chemistry, University of psala, during 1948–51, with financial assistance m A. B. Stockholms Bryggerier, Stockholm. tailed results will be published elsewhere.

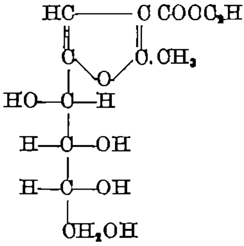
Biosynthesis of Vitamin C and a New Precursor

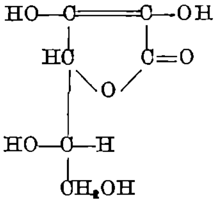
IEXOSE sugars and sugar acids have long been own to be concerned in the biosynthesis of vitamin [3], and it was also reported by Nath *et al.*[4,5] that ection of acetoacetate causes an immediate rise blood sugar in the rabbit and accelerates the biothesis of vitamin C in the animal system; although a higher dose of 180 mgm./kgm. causes about per cent decrease in vitamin C in the blood of bits in half an hour, an increase to the extent of per cent is observed in rats under identical conons, thus indicating the enormous capacity of s for the biosynthesis of vitamin C in their bodies, showing at the same time the possibility of toacetate being concerned in the process too.

Vith the view of gaining some insight into the mechsm, glucose and acetoacetate (sodium salt), both arately and combined, were added to the medium d for germination of a legume—green gram *aseolus mungo*). The seeds were first soaked in s-distilled water for about three hours prior to ping them in the presence of various aqueous lia containing these different substances at pH 7·4. each experiment, 500 seeds were taken and cted in such a way that each group had almost al weight.

ecause glucose has been found to condense with oacetate *in vitro*[6,7] to give rise to a product— tra hydroxy butyl 5-methyl 4-carbethoxy furan the structure of which resembles to a great ınt that of ascorbic acid (II), and because both constituents of (I) were found to be concerned he biosynthesis of (II), it was also decided to ly its effect in the process of biosynthesis of min C. This condensation product (I) was pared according to the method of West[6], with it modification, as follows.



(I)

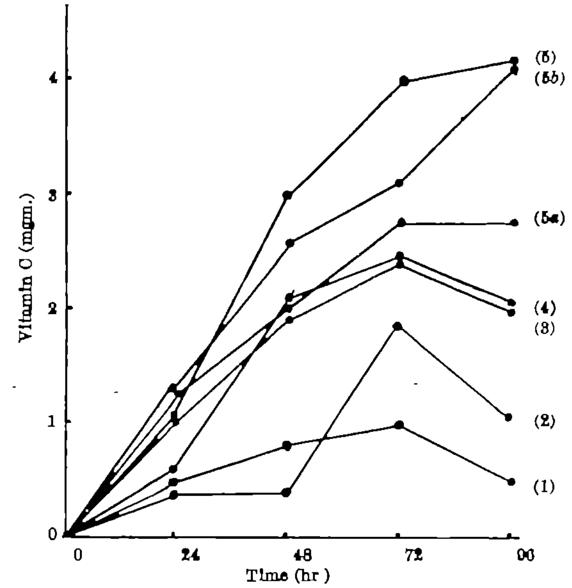


(II)

)0 gm. of glucose finely powdered was mixed oughly with 100 gm. of fused zinc chloride; this ture was then introduced in a round-bottomed 'ex' flask, which was immersed in boiling water, 50 gm. of ethyl acetoacetate and 50 c.c. of lute alcohol were added. The mixture was then rously stirred continuously until a heavy yellow p was obtained, approximately in about 25 min. ing this period of reaction, absolute alcohol (50 was again added for the second time. The syrupy s was then poured into about 150 c.c. of water kept overnight in the refrigerator, when fine ening needle-shaped crystals of the condensation luct of glucose and acetoacetate were found to separated out. The crystals were then separated from the mother liquor and washed repeatedly with ice-cold water. The substance was freed from adhering glucose and other impurities by repeated crystallization from hot water. The yield was about 25 gm. The substance melts sharply at 153° C. (corrected) and $[\alpha]^{20}_{D}$, as found by West[6], is $-19{\cdot}00°$ in water.

In order to prevent the ascorbic acid formed from being auto-oxidized during the process of germination, potassium *meta*-bisulphite, concentration 300 p.p.m., was added to all the different media, as recommended by Kendrick and Downer[8]. After the specified periods of germination in the dark, 100 seeds were removed from the dish, the testa removed and extracted repeatedly (thrice) with meta-phosphoric (3 per cent)–acetic acid (8 per cent) mixture, and vitamin C estimated according to the modified titrimetric method of Bessey[9].

All the experiments were repeated three times, and their average values, obtained with each type of substance in the germinating media after 24, 48, 72 and 96 hr., respectively, are shown graphically in the figure. The mean deviation in no case exceeded ± 0·18 up to 72 hr. This experiment was repeated several times, and the direct method of Roe and Kuether[10] (that is, by coupling the dehydroascorbic acid, formed by oxidation, with 2-4 dinitro phenyl hydrazine), which is much more specific for vitamin C, was used. Almost similar results were obtained by



Effect of various substances (in equimolecular quantity) on the amount of vitamin C formed during germination of 100 seeds (green gram): (1) acetoacetate (sodium salt) (72 mgm. per 100 seeds); (2) glucose (100 mgm.) and acetoacetate (72 mgm.) mixture per 100 seeds; (3) water, (4) glucose (100 mgm. per 100 seeds); (5) condensation product of glucose and acetoacetate (152 mgm. per 100 seeds); (5a) condensation product of glucose and acetoacetate (5 mgm. per 100 seeds), (5b) condensation product of glucose and acetoacetate (25 mgm. per 100 seeds) this method also, thus confirming that the substance responsible for the decolorization of the indophenol dye in Bessey's method is nothing else but the ascorbic acid.

It is quite evident from the graph that, although glucose alone (100 mgm. per 100 seeds) has but slight effect in increasing the concentration of vitamin C, sodium acetoacetate alone (equimolecular quantity) decreases the same considerably, while a combination of the two in equimolecular proportion shows sudden acceleration after 48 hr.; and it is interesting to note that the freshly prepared crystalline condensation product (I) shows gradual increase in the quantity of vitamin C even from the very beginning, and the result after 96 hr. is more than 100 per cent higher than that with glucose alone, thus showing the possibility of its playing the part of a precursor of ascorbic acid and of doing away with the possibility of acting as a catalyst only.

It is worth noting also that even a very low concentration of the condensation product (5 mgm. per 100 seeds) is much more effective than a much higher concentration of glucose (100 mgm. per 100 seeds), and the result with 25 mgm. per 100 seeds is as high as with 152 mgm. after 96 hr.

A sudden rise in vitamin C in case of glucose plus acetoacetate after 48 hr. may also be the result of formation of the condensation product through enzymatic processes during the course of germination.

Further details will be published elsewhere.

Permeability of Yolk of the Hen's Egg to Bromine-82

To investigate the resistance to diffusion between the two phases of the egg, the 34-hr. isotope of bromine (^{82}Br) as bromide was injected into the white in many eggs and its penetration into the yolk measured after various periods of time. About 5 ml. of the white of the egg to be injected was mixed with ¼ ml. of the radioactive bromide in isotonic solution, and injected as uniformly as possible throughout that remaining in the shell. The egg was maintained during the experimental period at 1° C., and, at its conclusion, frozen in a mixture of ether and dry ice. The yolk and white could then be separated cleanly with a sharp blow, and were conveniently diluted and their activities measured with a Geiger–Muller counter dipping into the liquids.

While the white was frozen, it was possible to scrape its entire inner surface, to collect the scrapings, and to analyse them separately. This showed that the activity of the layer in contact with the yolk was half that in the main mass of the white aft 5–10 min., and that after 1 hr. there were no long significant differences.

The rate of entry of the bromine-82 into the yc was found to be constant between 5 and 200 h the longest experimental time which was practicab when the activity reached, in the mean, 2·5 per ce of that in the white. This suggested that the penetr tion was across a single resistant barrier surroundi the yolk. That this was not the only obstacle w made evident when the distribution of the pen trating material within the yolk was studied. T superficial layer of the frozen yolk was sliced c weighed, and analysed separately, and it was fou that, even after 100 hr., one-third of the bromine- remained in the outermost 0·4 gm., correspondi to a thickness of about 0·1 mm. It is clear th after having passed the external resistant barrier, t ion still encounters an obstacle to its penetration in the yolk, and one is led to postulate a second barr some tenths of a millimetre below the first; it is be presumed that this system of spaced-out barri would be repeated towards the centre of the yolk.

Before the fifth hour, the amount of bromine- found in the yolk is greater than that expected fr the constant rate of entry found later. This exc of bromine-82 relative to its concentration in t layer of white in contact with the yolk, is marked lower in the shortest experimental times, suggesti that it is not due to contamination of the yolk the white during or after freezing, but rather the penetration of the ion into an outer layer yolk before the first resistant barrier is reache As the vitelline membrane in the frozen egg variably remained attached to the white, it wou seem that this cannot be the resistant barrier question.

A full account of the work will appear elsewhere.

Single-spore Cultures of Heterothallic *Saccharomyces cerevisiae* which mate wit both the Tester Strains

Lindegren and Lindegren[1] observed that ra single-spore cultures produce abundant copulati tubes when the culture reaches full growth, and th the cells from these cultures can conjugate with t cells of any other culture irrespective of its bei (+) or (−). They regarded this as a loss of d criminatory power due to a mutation of the ge producing copulation tubes.

During an investigation of the mating system Danish baking yeast, *Saccharomyces cerevisiae*, thı such 'highly fertile' cultures were found. Each them showed the formation of copulation tubes wi both the tester strains. When original cultures we examined, abundant copulation tubes and zygo were seen in each of them.

It was decided to isolate single cells and gr single-cell progenies, in order to see whether ea cell belonging to these 'highly fertile' cultures h lost the power of discrimination and could mate wi both the tester strains or not. Five cells with copu tubes and six ordinary vegetative cells were ated from one of these cultures. Single-cell tures were grown from them and tested for their ting capacity. As seen from the table, out of cells with copulation tubes, four gave a (+) ting reaction and one a (—) reaction; likewise, the six vegetative cells, one gave a (+) mating ction and five a (—) reaction.

Nature of cells isolated	No of cells isolated	No of single cells showing a (+) mating reaction	No. of single cells showing a (—) mating reaction
lls with opulation ubes	5	4	1
egetative ells	6	1	5

The facts that each of the single-cell progenies m the single-spore culture gives mating reaction h only one of the two tester strains, and that genies from some cells prove to be (+) and from ers (—), show that the mating responses of these cks with both the tester strains were due, not to s of mating discrimination, but to the creation of ls of opposite mating type within the culture ough mutation[2]. The simultaneous existence of h types of cells in the culture results in the pro- ction of copulation tubes and zygotes in these cks; and when they are tested with the tester ains, (+) cells in the culture produce copulation es on crossing with (—), and (—) cells on crossing h (+). This explanation seems more plausible n to assume the same cell on different occasions l respond to both as a result of loss of discrim- tory power.

Edmond About and the Technique of Freezing and Drying Tissues

THE procedure of freezing and drying tissues for purposes of histology is commonly known as Altmann or Altmann–Gersh method. Altmann blished his method in 1890[1], and Gersh, in 1932[2], scribed fundamental improvements in the tech- ue. It is curious that in 1862 the basic principles the method were described in "L'homme à l'oreille sée", a scientific romance by Edmond About, an glish translation of which was available in 1867.

About describes how the frozen body of a French soner was carefully dehydrated *in vacuo* over phuric acid and calcium chloride and preserved a German man of science during the Napoleonic ars. The technical detail given by About is very usible; he describes how the quality of the ezing was checked by observing the perfect servation of the red blood cells. This is a test t I personally used before reading the book.

have not been able to discover any information to the extent of About's scientific training, and suggestions as to the source of his ideas can only speculation. The discovery of the technique of frozen sectioning is given by Mann[3] as 1842, and it is possible that About knew of this technique and improved on it for his story. It is also possible that he was elaborating the legends of bodies being recovered from glaciers.

It is a pleasing speculation to suggest that a German histologist may possibly have obtained the idea for a fundamental technique from reading a scientific romance.

I am indebted to Dr. Henri Firket for bringing the book to my notice.

Terminology applied to Computing Machines

MAY I suggest that a protest is overdue against the anthropomorphic character of the terminology that is being applied to electronic digital computors? To the layman the use of such a terminology seems to ascribe human or near-human properties to these machines. Not only is it undesirable to use such terms, but also it is quite unnecessary, as alternative engineering terms are well established.

Those who describe electronic digital computors often use the term 'instruction', for example, when speaking of what is done to the machine by the operator. The word 'teaching' has even crept in. In engineering, the words 'setting' or 'adjustment' have exactly the same meaning. Why not use them? Numbers associated with these devices are given the name 'information' where the established term is 'readings'. Enthusiasts for electronic digital computors speak of the 'memory' of these machines; engineers would, instead, speak of 'records' or 'stores'. For the symbols that represent numbers in the mechanism, again, these enthusiasts have introduced the term 'machine language' where an engineer would say 'code'. Perhaps worst of all, a predetermined sequence of events in a digital electronic computor has been spoken of as a 'decision' of the machine.

Biologists and other men of science are careful to warn against anthropomorphic interpretations of animal behaviour. They avoid the word 'decision' when speaking of animals lest it convey to the lay public the suggestion that the animal's powers of volition resemble those rightly or wrongly assumed when the word is applied to human affairs. They are right, for many fallacies are rooted in anthropomorphic habits of thought. Is it wise, then, to encourage the lay public to believe that electronic digital computors possess rudimentary powers of scholarship, reasoning and volition, and that they may be thought about in a way that would be deprecated if applied to lower animals? There is abundant evidence that, aided by the new unfortunate terminology, such a notion is being spread. Hence this protest.

Thursday, October 2

ASLIB, NORTHERN BRANCH (in the Council Chamber, Guildhall, Kingston-upon-Hull), at 11 a.m.—Conference.

ROYAL AERONAUTICAL SOCIETY (at the Institution of Mechanical Engineers, Storey's Gate, St. James's Park, London, S.W.1), at 6 p.m.—Mr. R. E. Hardingham: "Maintaining Airworthiness in Operation" (Eighth British Commonwealth and Empire Lecture).

Friday, October 3

ASSOCIATION OF APPLIED BIOLOGISTS (in the Mining Lecture Theatre, Imperial College of Science and Technology, Prince Consort Road, London, S.W.7), at 11 a.m.—Papers on "Forestry Problems".*

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

SCIENTIFIC OFFICER and an ASSISTANT EXPERIMENTAL OFFICER—The Secretary, The Hannah Dairy Research Institute, Kirkhill, Ayr (October 6).

ASSISTANT LECTURER IN THE DEPARTMENT OF GEOGRAPHY (knowledge of cartography is desirable)—The Registrar, Queen Mary College, Mile End Road, London, E.1 (October 7).

LECTURER and an ASSISTANT LECTURER IN THE FACULTY OF EDUCATION at Makerere College, University College of East Africa—The Secretary, Inter-University Council for Higher Education in the Colonies, 1 Gordon Square, London, W.C.1 (October 10).

SENIOR RESEARCH OFFICER (with honours degree in physics or engineering, proven research ability, experience of length measurement and in handling of staff) IN THE DIVISION OF METROLOGY, National Standards Laboratory, New South Wales, to undertake research work in a well-equipped laboratory and to supervise work of the Length Section—The Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2, quoting No. 3984 (October 15).

DEPUTY DIRECTOR OF RESEARCH—The Director of Research, British Leather Manufacturers' Research Association, Milton Park, Egham, Surrey (October 2[illegible]).

LECTURER IN PHYSICS (with an honours degree and experience in research), and an ASSISTANT LECTURER IN PHYSICS (with an honours degree: research experience would be an advantage), at Canterbury University College, Christchurch, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (October 20).

ASSISTANT LECTURER IN MATHEMATICS at the University College of the West Indies—The Secretary, Inter-University Council for Higher Education in the Colonies, 1 Gordon Square, London, W.C.1 (October 25).

ASSISTANT LIBRARIAN and LIBRARY ASSISTANTS at the University of Malaya, Singapore—The Secretary, Inter-University Council for Higher Education in the Colonies, 1 Gordon Square, London, W.C.1 (October 30).

LECTURER (qualified either in mathematical statistics, or in pure or applied mathematics, but preferably with special knowledge of statistics) IN THE DEPARTMENT OF MATHEMATICS, University of Cape Town—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (October 31).

LECTURER IN THE DEPARTMENTS OF MATHEMATICS AND APPLIED MATHEMATICS, University of Natal, Durban—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (October 31).

RESEARCH FELLOW (with a science degree of at least second-class honours and experience of ecological work in the field) to engage in fundamental research to determine the carrying capacity of the Hluhluwe Game Reserve, Zululand, in respect of certain animals, notably zebra and blue wildebeeste—The Secretary, Natal Parks, Game and Fish Preservation Board, P.O. Box 662, Pietermaritzburg, Natal, South Africa (October 31).

DIRECTOR OF STUDIES (with good academic qualifications and educational experience; university teaching experience would be an advantage) for the Royal Air Force College, Cranwell, to be responsible, under the Commandant, for directing and supervising the educational course in scientific, technical and humanistic subjects—The Air Ministry, S.2(c), Cornwall House, London, S.E.1.

HEAD OF THE MATHEMATICS DEPARTMENT (with a good honours degree and good experience in teaching mathematics to advanced students of technical and university colleges)—The Registrar, Technical College, Sunderland, Co. Durham.

JUNIOR SCIENTIFIC OFFICER (male or female, with an honou degree in general science, pharmacy or biology) to undertake tec nical work in the Blood Transfusion Service Laboratory—The Direct Regional Transfusion Centre, Roby Street, Manchester 1.

PHYSICIST (with honours degree) for work in Technological Depa ment involving investigations into friction and measurement a control of yarn tension—The Secretary, British Rayon Resear Association, Barton Dock Road, Urmston, Manchester.

SCIENTIFIC OFFICER and an ASSISTANT (Scientific) IN THE ME POLITAN POLICE LABORATORY—The Secretary, Room 163, N Scotland Yard, London, S.W.1.

AN AUSTRALIAN ACADEMY OF SCIENCE

IN 1951 the Australian National University organized a seminar on "Science in Australia" as part of the jubilee celebrations of the Federation of the Australian States. This gathering, generally representative of Australian science, was aided greatly in its discussions by the presence of Sir Edward Mellanby, from Great Britain, and of Dr. J. B. Conant, president of Harvard University. Scientific activity in Australia was reviewed in an endeavour to find how best it should develop in the future. It had become clear that in a country of such large size, with a scattered scientific community, where responsibility for scientific work is divided between the universities and institutions of the various States, on one hand, and those of the Commonwealth Government on the other, it is extremely difficult to preserve unity and to ensure that achievement is recognized and fostered. The relative isolation of Australian scientists, not only from scientists abroad, but also from their colleagues within Australia, is a major hardship. Much has been achieved and science has made a great contribution to the welfare of Australia; but it is felt that the development of an integrated scientific community will stimulate greater progress. For these reasons the proposal by Prof. M. L. Oliphant that active steps be taken to found an Australian Academy of Sciences received strong support.

The idea of a national scientific body in Australia is not new. Several attempts have been made in the past to establish an institution to encourage the pursuit of natural knowledge as do the Royal Society in Great Britain and the various national academies of science in Europe and America. These attempts were frustrated by the time and expense involved in bringing even a small number of men of science together for regular meetings in the days before air travel virtually eliminated time consumed in movement about Australia, or a rapidly growing public appreciation of science, and the part played by science in the development of the country, made it easier to obtain financial support for scientific activities. Inter-State jealousies, and the fear by the States of encroachment by the Commonwealth upon their rights and privileges, added to the difficulties encountered.

The only effective scientific body which covered the continent was the Australian and New Zealand Association for the Advancement of Science (A.N.Z.A.A.S.), closely resembling the British Association in the United Kingdom. The periodic meetings of the Association became the natural means of personal contact between scientists. The sectional sessions became serious scientific discussions, and the habit grew of holding meetings and congresses of scientific societies during the gatherings of A.N.Z.A.A.S. It was natural, therefore, that the endeavour after the First World War to form international scientific bodies should result in the formation of a National Research Council (A.N.R.C.), at first as an independent body, but later composed of the Australian Fellows of A.N.Z.A.A.S.

Within the limitations imposed by lack of funds and its diffuse membership, A.N.R.C. has done a great deal for Australian science. In particular, it has fostered national and international congresses, encouraged the pursuit of anthropology, urged the development within the universities and government institutions of necessary scientific activities, and has given advice to State and Commonwealth governments upon matters affecting research and teaching in science. Its members have been informed of its activities through the publication of the *Australian Journal of Science*; it has established and maintained responsibility for the anthropological journal *Oceania*, and more recently has collaborated with the Commonwealth Scientific and Industrial Research Organization in the general supervision of the *Australian Journal of Scientific Research*. However, because of its very restricted resources, the A.N.R.C. has been entirely dependent upon a few devoted officers in Sydney and Melbourne, between which cities the Executive Council has alternated every few years; members of this Council from other States have been unable to attend its meetings and have had to nominate proxies, while lack of contact between the ordinary members has led to growing apathy on the part of the majority.

For these and other reasons, including the relationship with A.N.Z.A.A.S., it became the general feeling of members that there was little prospect of reforming A.N.R.C. from within so that it could discharge effectively the functions of a national body representative of science in Australia.

Dr. D. F. Martyn and Prof. M. L. Oliphant decided to make a fresh approach to the problem by inviting the Fellows of the Royal Society resident in Australia to become the foundation members of a new organization. This group of thirteen chose eleven other Australian scientists, who it was unanimously agreed should be potential members of an Academy, to sit with them as founders of the new body. The A.N.R.C. was kept fully informed at all stages of the discussions, and joint meetings with its Executive Committee were held in Sydney and in Canberra. At the annual meeting of A.N.R.C. on August 19, unanimous approval was given to the proposals for an Academy, and it was decided that when in active operation it will take over the present functions and responsibilities of A.N.R.C. It is a tribute to the spirit of Australian science that, in the common cause, some 150 scientists should, by this action, have withdrawn voluntarily from immediate participation in the government of the principal scientific society in the country.

At an early stage in the discussions representatives of the embryonic Academy were received by the Prime Minister, who expressed keen interest in the proposed institution and said that his Government would give sympathetic consideration and support to a national body which was adequately representative of Australian science and which had ensured that it would maintain high standards.

The task before the foundation group of the Academy is now to draw up a constitution, statutes and rules and to apply for a Royal Charter. Th Commonwealth Solicitor-General and his Office hav agreed to give guidance upon procedures.

Since the pursuit of science is now a major activit in a developing Australia, it is probable that th Fellows of the Academy will number eighty in th course of time. This would be approximately th same proportion, on a population basis, as th Fellowship of the Royal Society in Great Britair However, it is not anticipated that the number c Fellows in the early years will rise rapidly abov about fifty.

In order that the wide representation of scientifi men provided by A.N.R.C. should not be destroyec and to foster regional interest in the Academy, it ı contemplated that a number of regional committee will be established consisting of Fellows of th Academy resident in a region together with a numbe of local scientists who are not Fellows. These regiona committees will have no part in the government c the Academy, but will advise the parent body upo the scientific problems and needs of the widel dispersed parts of the continent.

The headquarters of the Academy will be in th Federal Capital, Canberra, where it is hoped tha suitable accommodation will be provided. Th government of the Academy will be modelled upo that of the Royal Society, with modifications to su Australian conditions.

The foundation group of the new body consists c the following Fellows of the Royal Society: Si Douglas Mawson, Antarctic explorer and professo of geology in the University of Adelaide; Sir Davi Rivett, formerly chairman and chief executive office of C.S.I.R.O. and formerly professor of chemistry ı the University of Melbourne; Sir Macfarlane Burne director of the Walter and Eliza Hall Institute c Medical Research in Melbourne; Prof. J. C. Eccle professor of physiology in the John Curtin School c Medical Research, Australian National University Prof. O. Tiegs, professor of zoology in the Universit of Melbourne; H. R. Marston, chief of the Divisio of Nutrition and General Biochemistry, C.S.I.R.O. Adelaide; Prof. T. G. Room, professor of math matics (pure), University of Sydney; Dr. D. F Martyn, chief scientist of the Radio Research Boarc Canberra; Prof. J. A. Prescott, director of the Wait Agricultural Institute, Adelaide, and professor c agricultural chemistry in the University of Adelaide Prof. K. E. Bullen, professor of mathematics (applied University of Sydney; Prof. D. G. Catcheside, pro fessor of genetics in the University of Adelaid (Waite Institute); Dr. R. Lemberg, Institut of Medical Research, Royal North Shore Hospita Sydney; and Prof. M. L. Oliphant, director of th Research School of Physical Sciences, Australia National University; together with the following Prof. R. v. d. R. Woolley, Commonwealth astronome and professor of astronomy in the Australian Nation University, Commonwealth Observatory, Canberra J. Pawsey, assistant chief of the Division of Radio physics, C.S.I.R.O., Sydney; Prof. R. J. W. LeFevre professor of chemistry, University of Sydney; Prof S. Sunderland, professor of anatomy in the Universit

Melbourne; L. Clunies-Ross, chairman of C.S.I.R.O., elbourne; Prof. T. M. Cherry, professor of mathe- atics, University of Melbourne; Prof. L. G. Huxley, ofessor of physics in the University of Adelaide; rof. E. S. Hills, professor of geology in the University Melbourne; A. J. Nicholson, chief of the Division Entomology, C.S.I.R.O., Canberra; Prof. L. H. artin, professor of physics in the University of elbourne; with Prof. H. K. Ward, chairman of .N.R.C., as an observer. Dr. D. F. Martyn is acting secretary *pro tem.*

THE AMERICAN FARMER AND HIS WOODLANDS

orestry in Farm Management

y R. H. Westveld and the late Ralph H. Peck. econd edition, revised by R. H. Westveld. Pp. i+340. (New York: John Wiley and Sons, ıc.; London: Chapman and Hall, Ltd., 1951.) 0s. net.

ALTHOUGH I have not had the good fortune to visit the United States and its forest areas, I el that an intimate knowledge of American forestry ractice is not necessary in order to recognize the erits of this admirable book. If there was a British ersion (and how valuable it would be), it could well e renamed "Forestry in *Estate* Management", since is book would appear to have more in common with state forestry in Great Britain than with farm oodlands as we know them over here.

Judging from the advice offered to American eaders, it would seem that there are many aspects f private woodland management which are common both countries. The effect of the Second World Var, the need for efficient utilization, the absorption f certain types of woodland produce (such as fencing aterial) by the grower on his own property, the hristmas tree market, and the need for proper ecords and accounting, are only a few examples.

The first chapter deals with the relationship etween agriculture and forestry, the contribution hich forestry can make to food production, and the eason why forestry fails to do so in some cases. The gures quoted are, of course, in respect of the United tates. The next two chapters are concerned with hat may be described as the elements of forestry, he choice of species, site requirements, how a tree rows, even-aged and uneven-aged woods, and ensity and methods of propagation, being some of he points which are considered.

The problem of damage by natural and artificial auses, and the steps to be taken in combating them, re covered by parts of the third and fourth chapters. he greater portion of the fourth chapter deals, owever, with forest management. Under this eading, particular attention is directed to the need or improving immature and partially stocked areas; oth these matters are often the concern of foresters n Great Britain to-day. Thinning and pruning are lso considered in this chapter. It is interesting to bserve that, although natural regeneration and election cutting', 'group-selection cutting' and helterwood cutting' are dealt with, no reference is ade to sylvicultural systems as such. Doubtless the uthors thought that it was unnecessary for their eaders to delve too deeply into these matters.

Chapter 5 is devoted to planting and refers, *inter alia*, to planting compared to direct seeding, to pure and mixed stands, to the choice of young stock and to spacing. On the subject of methods of planting it is interesting to see that the method known in Britain as 'pit-planting' is referred to as 'hole-planting', and 'notch-planting' as 'slit-planting'. The remarks on planting machines are particularly interesting, since this equipment has not yet appeared in Britain to any general extent. The type described has a planting capacity of approximately ten thousand trees per eight-hour day with a crew of two. If a man plants by hand 500–700 trees per day under 'average' conditions, a planting machine will show an eight- or nine-fold increase, which is a very substantial amount. The cost of the machines varies from 200 to 750 dollars (approximately £70–250). As regards planting costs, a formula for ascertaining these is given, and it is added that costs vary from 6 to 30 dollars per acre (£2–10) including the trees. Even allowing for wide spacing, cheap trees, and without rabbit netting, such as we have to erect in Britain, these figures seem very low. Without netting, costs in Britain are seldom less than £25 per acre, and with netting may well be £40 per acre for small areas.

The following four chapters deal with measurement and utilization, including felling and extraction, marketing, conversion and preservation. Chapter 11 covers three special forest products: Christmas trees, rosin and turpentine (known in the United States as 'naval stores'), and maple sugar. This is followed by a chapter on the preservation of wild-life in forestry. Finally, two chapters are added covering 'forest plans' and records, and State aid to woodland owners. There are eight valuable appendixes on various subjects.

The book is well illustrated, with some excellent line drawings; but the quality of the photographs is not up to the standard one would expect. The text includes adequate headings, and is well tabulated. This book should be of great value in the United States, and is bound to be of much interest to anyone in Britain who wishes to increase and broaden his knowledge of forestry. N. D. G. JAMES

A STUDY IN CULTURE CONTACT

From Black to White in South Australia

By Ronald and Catherine Berndt. Pp. 313+5 plates. (Melbourne: F. W. Cheshire Pty., Ltd.; London: Angus and Robertson, Ltd., 1951.) 37*s.* 6*d.*

WITH few exceptions, the effects of European domination on any of the simpler native societies are fairly predictable—a period of mutual hostility, distrust and misunderstanding, the break-down of the traditions, ties and sanctions that held the indigenous culture together, a further period of 'drifting' and general social maladjustment, and, finally, the very gradual absorption of the sub-ordinate people into the lower strata of European society. Depending mainly on the cultures involved, this process may be accomplished with varying degrees of difficulty; but the history of Colonial development shows that it never has been, and perhaps never can be, entirely painless for the native peoples concerned.

In Australia, the difficulty experienced by the Aborigines in making the required transition was intensified by three factors. First, their small numbers; it has been estimated that the Aboriginal population has never been large, probably at no time exceeding half a million, scattered over the entire continent and living in small groups which were not accustomed to act in any organized unity. Second, although their religious and social structure was highly complex, technologically these people were among the most backward known. Finally, besides being, by European standards, physically unprepossessing, the Aborigines had an outlook and ideology which was, to the first settlers, foreign and 'barbarous' beyond any hope of understanding. The effect of these factors was that the Aborigines were able to offer no resistance to European settlement, which might have given them a 'breathing-space', however temporary; their absence of technology inspired the Europeans with a supreme and lasting contempt for their 'primitiveness', an attitude reflected in subsequent dealings with them; and, finally, the complexity and uniqueness of their social system not only made native adaptation to the new order excessively difficult, but also nullified most attempts at compromise made by the new-comers, so that humane intentions were often changed to exasperated bewilderment.

In their treatment of this problem, Mr. and Mrs. Berndt have restricted their discussion to South Australia, where they have selected four areas which typify four successive stages of the general Australian contact situation.

The first, Ooldea, is an 'outback' area. The natives of this district still retain, in modified form, much of their old nomadic tribal life, although they are becoming increasingly dependent on 'hand-outs' of government rations. The main source of contact here, however, is the United Aborigines' Mission, whose activities attract some extremely caustic criticism. With an earnest *naïveté* and a sense of values it were kindest to describe as 'misplaced', this body has made it a deliberate policy to condemn every aspect of native life, and, more seriously, to alienate, by every means in its power, the children under its control from their families and their tribal background. In return, it offers the Word; that the Word might Itself have meaning only in a particular cultural context does not seem to have occurred to them. The result of this disruptive policy is that the products of this Mission's training are left in a sort of cultural hiatus, severed from their traditional culture, yet not prepared for or admitted to European society.

The second district, Oodnadatta, is also an undeveloped area, but without mission influence. Here we see the process of acculturation beginning to take effect. The natives fall into three fairly distinct groups: labourers living in a squalid camp outside the town, disliked and despised by the Europeans; those living in the town (mainly women married to non-Aboriginal husbands) who form an amorphous section with no affiliations to either cultural group; and (the smallest section) women married to respected members of the town who enjoy an uneasy acceptance by the white community.

The third area carries the process a step further. The native population here is almost entirely mixed-blood and has attained the general living standard of 'poor whites'. The men are casual labourers, the women mostly prostitutes, and only traces survive of the old culture. The gradual infiltration to highe social levels continues.

In the fourth area, the city of Adelaide, accu turation is almost complete. Most of the people a scattered through a large slum area where they liv on equal terms with their white neighbours.

The authors' treatment of this theme, while exce lent so far as it goes, seems most suitable for the la reader. The anthropologist who has not specialize in this area would like to know, for example, mor about the nature of the native's ties to his 'ow country' and why separation from it means degene ation and collapse; and more precise details of th modifications in the kinship structure, which, th authors inform us, is one of the last features of th old culture to survive. The book is a fairly adequat account of a situation, but the characters of th protagonists, which give the conflict its specifi flavour, are insufficiently analysed.

The book is nicely presented, but contains a numbe of misprints, including two in section-heading (contents page and p. 125)—regrettable carelessne in a book published at this price. D'ARCY RYAN

FOOD FOR THE URBAN MASSES

Townsman's Food

By Dr. Magnus Pyke. Pp. 212. (London: Turnstil Press, Ltd., 1952.) 15s. net.

THIS is a readable little book, but whether i fulfils its objective "to try to describe for a intelligent and non-scientific reader some of th technical problems of modern food industry, and t examine the aims and purposes of its technique an policy" will be dependent on the degree of understanding of the non-scientific reader.

I am of the opinion that in describing some of th problems the author has achieved his object, that i his examination of the "aims and purposes" he i slightly less successful, and that in considering "policy" his contact with the Ministry of Food ha biased his mind and that far too much space i devoted to war-time rules and regulations.

Whether such books are essential, whether or no they do any good, is a moot point. Certainly thi publication has enabled both 'special correspondents and learned academic people to write startling (and absolutely ill-informed) reviews in which the cunning methods of sophistication adopted by the moder food-manufacturer and the possible danger to th public are stressed out of all proportion.

To gibe at the food-manufacturer is popular these days, and in many places in the book there is a 'sting in the tail' of a sentence. For example, the author, on commenting on the colouring of margarine by th British manufacturer, says (p. 19), "is he then no contributing to the national nutrition if the colourin artifices he adopts to make his product resembl butter, succeeds in persuading people to eat it—even though these manœuvres were originally adopted t increase his sales, and hence his profits ?" Artifices, manœuvres, sales and profits !

The use of glyceryl monostearate as an emulsifying agent is mentioned (p. 123): ". . . its employment in the food industry has been viewed with a certain element of thoughtfulness. Its development is closely related to progress in the field of soapless detergents". One feels that the author enjoyed writing such aragraphs ; he perhaps did it with his tongue in is cheek.

The chapters dealing with various groupings of od are well balanced ; perhaps the section on bread slightly too long, and in the section on milk the ferences to the unpasteurized versus pasteurized ontroversy would appear, in these days, to be rchaic.

The author repeatedly stresses the difficulty of eding a population such as that of the British les, with its congested urban districts, and gives ll credit to the food technologist for making it ossible to supply the people with food.

It is probable that the population in Great Britain as the purest food in the world, not excluding the nited States, and one can agree with the author at the motives which stimulate the large food-anufacturer are (p. 203) "firstly honesty, and condly enlightened self-interest".

The book is worth reading, if only to decide hether the reviewer is right or wrong.

L. H. LAMPITT

THE GLASS-POLISHER'S ART

rism and Lens Making

Textbook for Optical Glassworkers. By F. Twyman. econd edition. Pp. viii+629. (London : Hilger and Vatts, Ltd., 1952.) 58s. net.

THE earlier edition of Mr. F. Twyman's book was one of the first important works in English to ppear on the subject. Its value derived from the cord of his wide experience ; its weakness was that was almost entirely confined to the methods of one ctory. In the second edition the author has taken dvantage of the co-operation he has received to tend its scope ; in addition, there are a number of apters (more or less connected with the subject-atter) contributed by experts. The size (and cost) ave increased nearly fourfold.

Since the first edition the industry has become creasingly mechanized, and to this the diamond-nded tool has largely contributed. The applications this are well covered. The work of W. Taylor has en recognized, and the production and working of w materials have received adequate attention.

There are still a few (perhaps unavoidable) defects the presentation of other manufacturers' methods. little more information would be welcomed on the und-stroke polishing machine (only one type is ustrated) and the method of controlling figure, as done for the straight-stroke machine. There is ill rather much on the largely academic question air-conditioning; though most firms find this un-cessary, and even in the working of the 200-in. irror the elaborate plant devised was eventually andoned.

There is much valuable discussion on grinding and lishing materials, and the author has endeavoured introduce scientific precision. It would have been en more valuable if information about the sizes of rasive powders of other manufacturers had been ven. A new section deals with aspherical work, ough this again is not quite complete as to range work or methods of testing.

Two statements call for remark. One is that the thor does not know of any machine on the market ecifically designed for trepanning. Such a machine f British make) was on sale between the two World Wars ; the second is that an American surface generator has been constructed in which the whole sequence of operation is automatic. A British machine has also appeared (possibly while the book was in the press).

There are a few misprints and some omissions from the bibliography ; the rather scanty section on tool-making could have been enriched by reference to the machines for milling optical tools, illustrated in W. Ewald's "Das Optische Werkstatt" (a work mentioned in the text). Surprisingly, no mention is made of the trichlorethylene degreasing plant for cleaning lenses, nor of the method of supporting lenses in recessed tools.

These are all minor matters in comparison with the wealth of information made available. The book is throughout delightfully seasoned by the author's personality, and he will be forgiven for riding his hobby-horses so hard.

H. W. LEE

THE AVIAN PITUITARY

The Structure and Development of the Avian Pituitary from a Comparative and Functional Viewpoint

By Karl Georg Wingstrand. Pp. viii+316. (Lund : C. W. K. Gleerup, 1951.) 18 kr.

DURING the past three decades there have appeared hundreds of papers dealing with the microscopic structure and the functions of the pituitary in various Chordates; but, comparatively speaking, little attention has been paid to the pituitary of birds despite its fundamental role in the evergreen study of migration and the timing of breeding seasons. This most acceptable volume from Sweden will be the standard work on the subject for many years to come, for Dr. K. G. Wingstrand has been at great pains to attain a comprehensive view of the class—from Rattites to Passerines—as a whole rather than draw conclusions from a single species: that is, the atypical, non-seasonal egg-laying machine, the common fowl, which is usually put forward as an adequate representation for 'The Bird' in biological literature.

The work comprises fourteen chapters and covers the anatomy and embryology of the adenohypophysis and neurohypophysis and compares them, in various aspects, with those of reptiles and mammals. The innervation, and blood vascular relationships, of the pituitary are considered at length, including the hypophyseal portal system which, though studied intensively in various groups during the past few years, has been curiously neglected in birds prior to the contemporary publications of Benoit, Walter and Assenmacher.

Dr. Wingstrand has seemingly confirmed the validity of the 'avian pituitary pattern' of Rahn and Painter and has, in fact, found the caudal and cephalic lobes of the pars distalis to be recognizably different in representatives of no less than fifty genera. He adopts a most conservative attitude in regard to the distribution of the various α and β cell-types and, it follows, to their probable functions. It is further noteworthy that although the subject of neurosecretion is briefly dealt with, the Golgi 'network' (whatever, precisely, it is) is not considered, nor is it dealt with in Dr. Wingstrand's lengthy cytological discussions.

A. J. MARSHALL

SIR WILLIAM RAMSAY (1852–1916)

By Prof. J. R. PARTINGTON, M.B.E.

THE present week marks the centenary of the birth on October 2, 1852, in Glasgow, of one of the most distinguished of the many famous British chemists, William Ramsay. Both his parents came from families of notable people ; his paternal grandfather had been a chemical manufacturer in Glasgow, and his uncle on the father's side was Sir Andrew Crombie Ramsay the geologist. As a boy he showed already musical and linguistic talents ; in later life, at scientific meetings abroad he spoke in several languages to suit the nationalities of those whose papers he was discussing, and in proposing toasts at more convivial gatherings he followed the same practice.

Ramsay's interest in chemistry developed in his student days at the University of Glasgow, but extra-murally, since he had been educated for the ministry. In 1871 he went to Tübingen, where he took his doctorate, and on his return to Glasgow he became assistant in the chemistry departments of Anderson's College and then the University. His research work in this period was in organic chemistry, especially in relation to pyridine, an evil-smelling constituent of bone oil, stocks of which had been left in the cellar by a former professor, Thomas Anderson. His interest in physical chemistry (or, as he liked to call it, general chemistry) seems to have been aroused by E. J. Mills, then professor in Anderson's College (later the Royal Technical College). It was not until 1880 that Ramsay obtained his first professorial chair, at University College, Bristol. Here he showed another of his outstanding qualities, that of being an energetic and capable administrator, becoming principal of the College as well as professor of chemistry. His single demonstrator was Sydney Young, who later succeeded him as professor. Young was a very able experimenter and there is no doubt that he exerted a steadying and beneficial influence on Ramsay. Together they carried out work of outstanding importance on the vapour pressures and critical properties of liquids, which is still regarded as authoritative.

By now, Ramsay had become a chemist of international reputation. Always interested in teaching, he wrote in Bristol a small book, "Experimental Proofs of Chemical Theory for Beginners", on a very original plan. Another of Ramsay's traits was his open-mindedness towards modern theories ; his early adoption of the Periodic Law as a basis of classification of the elements (which he adopted in his larger "System of Inorganic Chemistry", published in 1891), and of the theory of electrolytic dissociation at a time when it was bitterly criticized by most other chemists, are both good examples of his receptiveness and judgment. He also participated in the earlier developments of the electronic theory of valency.

In 1887 Ramsay succeeded Williamson as professor of chemistry at University College, London. At that time the College had become part of the University of London, but the latter was purely an examining body, having no concern with teaching or research. The conditions at University College were not so good as those in Bristol when he left it, and accommodation for research was practically non-existen To some men such conditions are more stimulatin and beneficial than succession to an 'institut elaborately equipped and with a strong tradition research in a special direction. Towards the end Ramsay's life new laboratories, which in their tim were models of what a university chemistry depar ment should be, were erected ; but all his importa work was done in the old and modest accommodatio In 1888 he was elected a Fellow of the Royal Societ and in later life he accumulated a series of honorar degrees and memberships of learned societies whic must be without parallel. He was a well-know personality both on the Continent and in the Unite States, numbering among his friends practically a the notable chemists of his time. His friendship wit Ostwald, who did so much to further the cause physical chemistry at a time when the preponderatin interest was in organic chemistry, brought Ramsa into touch with a current of thought and of researc which was changing the face of classical chemistr and must have influenced his own work.

Up to 1894 Ramsay's work was in the field inorganic chemistry, in which he investigated oxide of nitrogen, and in physical chemistry, in which h investigated with Shields the effect of temperatur on the surface tension of liquids, leading to the wel known equation of Ramsay and Shields and to relation between surface tension and molecul weight. At University College also was carried ou the work of Linder and Picton on colloidal solution which is one of the foundation stones of moder colloid chemistry. It was in 1894, however, th Ramsay's great chance came. Lord Rayleigh w measuring the densities of gases and had found th nitrogen obtained from the atmosphere was apprec ably denser than that obtained from chemic compounds. He suspected that the lighter nitroge contained an unknown light gas, while Ramsa thought that the heavier nitrogen contained a unknown heavier gas. In 1894 he had a conversatio with Rayleigh, who so far back as 1892 had aske chemists if they could solve the mystery, and in very short time Ramsay was able to tell Rayleig that by heating atmospheric nitrogen with ma nesium, which combines with nitrogen, the residu gas was even heavier, suggesting that the heavi impurity in atmospheric nitrogen was a chemicall inert gas. Even at that time Ramsay had realize that there was a possibility that the Periodic Tab might be extended by a new group of gaseo elements, an event which he and his collaborato afterwards brought into being by the discovery these elements.

Rayleigh was working on lines suggested by forgotten experiment of Cavendish in 1785, who ha found that on sparking a mixture of air and oxyge over potash solution the gas slowly disappeared a a solution of saltpetre was formed from the alka and the oxides of nitrogen produced by the sparking but always a small residue of gas was left, about a p cent of the original volume of the nitrogen. By h magnesium method Ramsay also obtained this ine gas, and at the meeting of the British Association

894 the two announced to an incredulous audience hat the atmosphere contained a new gaseous element. Working independently, the two had reached the ame result and the discovery was announced by hem jointly. The full account of the work was given o a meeting of the Royal Society in January 1895. By then the density of the gas was found; it had been hown to be monatomic from the ratio c_p/c_v of its pecific heats as approximately 1·66, and its atomic weight was 39·9. The new gas was given the name argon'.

The day after the paper was read, Henry Miers, he mineralogist, directed Ramsay's attention to a gas evolved on heating uranium minerals and thought o be nitrogen. It might, he said, be argon. Ramsay prepared this gas, found that it gave a bright yellow line in the spectrum, and was inert. Crookes, with a sample of the gas sent him by Ramsay, identified the spectrum line with one which had been observed in he solar spectrum during the eclipse of 1868 by Lockyer, and supposed by him to belong to an element present in the sun to which he gave the name helium'. The new gas had, therefore, already been named. By the end of 1898 Ramsay, working with Travers, had discovered three more inert gases, neon, krypton and xenon, and with one exception the new group in the Periodic Table was filled. The remaining element linked this work with another field in which Ramsay made notable discoveries.

The year 1898, when the tale of the atmospheric inert gases had been told, saw the beginning of an epoch of scientific discovery without parallel in anything which had gone before. Radium was discovered by Mme. Curie. It was soon shown that radium emitted a radioactive gas called the emanation of radium (now radon). This was of great interest to Ramsay, who began work on the subject. His splendid manipulative skill, highly developed by having to deal with minute volumes of rare gases, was needed in handling extremely small quantities of radioactive emanation. In collaboration with Soddy, Ramsay soon showed that radon is an inert gas and that on standing it slowly changes into helium. In 1912 Ramsay and Whytlaw-Gray published the results of a determination of the density of radon in which only about a tenth of a cubic millimetre of gas was weighed on a micro-balance sensitive to two-millionths of a milligram. The atomic weight of radon found agreed with the assumption that it was formed from radium, atomic weight 226, by the emission of an alpha-particle which was chemically the same as a helium atom of weight 4; hence the atomic weight of radon should be 222, while the value 223 was found from the density on the assumption that it was monatomic. Radon then took its place as the last element in the inert gas group.

Ramsay's later work in the field of radioactivity was less successful and he was led astray by supposed transformations of elements, such as copper into lithium, under the influence of radioactivity. He realized, however, that the great concentration of energy made available in radioactivity was likely to lead to such transformations, a prediction achieved by later workers in this field. Ramsay took a great interest in the earlier applications of radioactive materials in medicine.

Ramsay was knighted in 1902 and his work on the inert gases gained for him the Nobel Prize in 1904. His administrative talent has already been mentioned, and during his tenure of the professorship at University College he was a president of the Society of Chemical Industry, of the Chemical Society, and of the British Association. He also took a keen interest in the character of the University of London, as a result of which and of the efforts of others, the University changed its former character of being a purely examining body and incorporated the constituent colleges as teaching institutions, at the same time giving their teachers a share in the examinations and the determination of the places of the candidates. Since then, the internal side of the University has greatly increased in importance and influence.

Ramsay had the keenest interest in research, inspiring his students and encouraging them by his example. Many of them have filled positions of distinction. At the end of the session of 1912 Ramsay retired from the professorship at University College. He was looking forward to the continuation of research; but this was not to be. He died on July 23, 1916, after a painful illness.

Kindly and sympathetic towards his students, friendly and courteous to his colleagues, enthusiastic and active in his work, Ramsay left memories of a great man, which he undoubtedly was. After his death, funds raised by public subscription were partly devoted to the building of a Chemical Engineering Laboratory at University College and partly to the foundation of a Ramsay Memorial Fellowship for advanced students of chemistry. At present, owing to monetary depreciation, the number of fellowships has had to be reduced to half the original number, and the University College Committee and the Ramsay Memorial Fellowships Trustees decided that the centenary of the birth of Sir William Ramsay should be made the occasion of a joint appeal for a total of £100,000, partly to restore the number of fellowships and partly to extend the chemical laboratories at University College. Both these objects, it is believed, would further the interests of the extension of scientific knowledge which were Ramsay's interests, and also, since the fellowships are international in principle, are in harmony with his constant desire to advance friendship and helpful collaboration among all scientific men. The Appeals Secretary, Ramsay Centenary Appeal, University College, Gower Street, London, W.C.1, will receive contributions from all who wish to help this cause and will give further information about the appeal. The Science Museum, South Kensington, has also organized a Ramsay Centenary Exhibition in collaboration with University College, which was opened on October 2 by Lord Woolton, Lord President of the Council, and will remain open to the public for three months (see p. 562).

FACTORS AFFECTING CHOICE AND JUDGMENT

It had been the intention to take advantage of the meeting of the British Association at Belfast to follow up the work of the informal conference on "Subjective Judgments" held in London in October 1950. It proved, however, to be difficult to realize this object within the present framework of the British Association, so that instead a series of papers were given which were not directly related to the work of the previous conference, the general title of the papers being "Some Factors affecting Choice and Judgment". Two of the papers, from the Road

Research Laboratory, Harmondsworth, dealt with social factors which affect the actions of road users; the other papers were of a more theoretical nature and dealt with factors affecting perceiving and judging under experimental, rather than everyday, conditions.

The attitude of the general science graduate to experiments involving subjective judgments is curious and illogical, even if understandable. He is taught throughout his study period to believe that those things which he measures during the course of his 'practical work' are facts, inviolable and true. His faith in them transcends the faith of religion. Above all, he believes in the dogma of Kelvin, that we must measure to be able to understand. He rarely succeeds in grasping the principles of uncertainty in physical measurement, and many years may pass before he realizes that all measurement demands a judgment on the compromise between accuracy and expediency. As a result, he dismisses all experiments which involve direct subjective judgments as being 'vague and inaccurate'. This dogmatic attitude is not confined to the young graduate. It finds its way into higher levels, where great efforts are made to develop physical analogues to supplant the human observer in a perceptual situation. Consequently, it happens that the experimenter who uses human subjects as indicators finds it necessary to go to unusual lengths to explain his means as well as his ends. Modern statistical methods have assisted greatly in the discipline of subjective judgment experiments. They serve in three ways: to enable the experiments to be designed on sound lines; to enable the results to be interpreted by a logical procedure rather than by inspection and induction alone; and to enable the results to be presented in a way which carries some conviction with the worker who believes that physical instruments alone can be used as indicators in experiments.

Statistical technique is a good servant, but an exacting master; it is appalling to contemplate the amount of observational and analytical work necessary to demonstrate statistically a factor the existence of which common sense has never had any reason to doubt. This must have struck forcibly those who participated in the Belfast symposium; but little improvement is likely to result until there is a change of heart in favour of a greater faith in the very real ability of human observers to give reliable judgments of their environment. The nature of this ability was demonstrated by Dr. R. G. Hopkinson, of the Building Research Station, Garston, who reported assessments of glare discomfort made under controlled conditions over a period of more than three years. With nothing to guide them but their sensations of glare discomfort, subjects had made settings of the physical variable controlling the sensation; the results showed only a very small variation in the mean values. Subjects who had passed through an initial 'sensitization period' could be relied upon to reproduce their findings to a useful order of repetition accuracy.

These findings apply to the conditions of a laboratory experiment. The work reported by the Road Research Laboratory was done under more natural conditions, records being made of the behaviour of road users, both drivers and pedestrians, to determine how this behaviour could be improved. The findings must be of interest to sociologists as well as to those concerned only with road safety problems. The work on driver behaviour suggests that improvement cannot result from legal restrictions alone unles there is a very great certainty of enforcement. Leg restrictions must be combined with clear evidence o the inevitability of enforcement, such as the presenc of a policeman in a strategic position, or with cle evidence of the inevitability of physical retribution— drivers will stop at a "Halt, major road ahead" sig if there is clear evidence of the existence of fa traffic on the major road. The same effects ar observable on pedestrians; a policeman at a crossin has a significant effect on those (chiefly men, it woul appear) whose normal behaviour at crossings i irregular.

The effect of propaganda on the behaviour of bot drivers and pedestrians could be demonstrate clearly; but propaganda alone is insufficient t maintain any permanent improvement. An exampl is that of the behaviour of both drivers and pedestrians on crossings. Propaganda alone improve behaviour at ordinary crossings, but not for long But propaganda added to the striping of crossings i the zebra pattern produced a more marked effect and one which remained, not indeed at the pea level attained during the initial stages, but nevertheless substantial.

These findings can be interpreted charitably on th assumption that the driver and pedestrian ar sensible adults. A driver will not obey legal restrictions unless there are manifest reasons why h should. In the absence of visible evidence o retribution, he will behave as common sense dictates He will not obey a speed restriction if there are n obvious hazards, nor will he stop at a road ahead i it is not likely to require such action. A pedestria will not use a crossing unless it is clearly beyond hi ability to get across the road without its aid. Bu equally the findings can be interpreted on th assumption that he is little more than a juvenil delinquent. This was the interpretation made in th paper by Mr. B. M. Foss, of Birkbeck College, London with especial reference to the personality of th 'car-plus-driver'. On this interpretation the roa user is anti-social, and will do any un-neighbourl action which he thinks he can 'get away with'. Th car driver can be expected to enlarge his 'body-image in relation to the size and horse-power of his car just as a man with a hat allows for his increase height in going under a low doorway. The body-image governs behaviour in a social as well as a physical sense. The driver with a large car find himself in a position of power, and his tendency i to exercise it to his own advantage, unless he i warned, say by the presence of a policeman, of the inevitable retribution which such behaviour wil bring.

There is a good reason for believing that much can be explained by the faith which the human subject has in his own abilities to make accurate judgments —a faith which, as has been suggested, is not shared by scientists nurtured in the nineteenth-century tradition. The pedestrian crosses the road without troubling to find a crossing, because he is sure that he can judge the distance and the speed of an oncoming vehicle, and hence is certain that he will be across before the vehicle can hit him. On the average his faith is justified, as the estimates given by the Road Research Laboratory show. But of course it is not the average man who gets knocked over. The distribution and variance of the speed estimates given by the work of the Laboratory show that there are occasions when the speed of an oncoming vehicle is rossly underestimated. Mr. Foss directed attention the fact that these lapses are more frequent in the eurotic and the fatigued; but many experiments, cluding those of the long series of judgments ported by Dr. Hopkinson, show that even the xperienced subject will on occasions show a wide eparture from his average judgment. If the 'average an' appreciated that his errors of judgment ight on, say, one occasion in fifty involve him a potentially fatal situation, he might exercise ore caution—but equally he might still take the sk.

In any experiment or situation involving subjective dgments, the apparent inevitability of big random rors must not be neglected. If a large number of bservers can make the judgment, these errors can e expected to cancel out. In practice it is often ifficult or impossible to obtain sufficient observers, e work has to be done with a small team, and Dr. opkinson's paper dealt with some of the problems hich arise in such a case. Experience of the experi- ental situation clearly has an effect. In the case f glare discomfort, there is a demonstrable increase sensitivity from day to day, apart from the random rors. After this 'sensitization period' is passed, e subject appears to maintain his criterion of nsation over a very long period, with a fairly onstant variance. It is therefore possible to decide e number of observations necessary from this bserver in order to eliminate, to a predetermined egree of probability, the random errors in his bservations. Consequently, an experiment employ- g a team of observers can be designed with a certain ecision. It remains to link the results with those hich would be expected to be obtained from a presentative selection of the population under the me conditions. This has been done for a few of e important situations, and it has been found that bout four-fifths of the general population are tisfied, or more than satisfied, with the average pinion of the team of experienced subjects. This plies, of course, to the particular problem of glare lighting, but the same procedure is applicable to her perceptual situations.

The exact reason for this 'experience effect' in bjective judgments did not emerge from the dis- ssion. It may be some form of accumulative emory-trace effect which should be capable of planation. It might well link up with studies of odern information theory. The techniques of the uilding Research Station experiments, which demand e control and variation by the subject of the ysical variable governing the sensation, involve e feed-back of information of the situation, which ust necessarily influence the judgment. These ctors need study and explanation. The judgment certainly influenced by the environment. This has en shown to be true in the judgment of spatial rection, as was demonstrated in the paper by Miss A. Phemister, of the Psychology Department, ueen's University, Belfast. There are preferred ames of reference, which assist judgment. If the dy is vertical, the subject can judge position and rection accurately, but if it is tilted, this facility to some extent lost. The apparent size of an object pends not only on the angular subtense of the ject at the eye, but also on its position in the me of reference. The moon near the horizon looks gger than when well up, to such an extent that all nds of explanations of the effect are made in terms refraction distortions—another example of the inclination of some trained scientists to search for an objective rather than a subjective explanation of a phenomenon.

One would have hoped that some discussion would have arisen on the training of subjects to make judgments: whether such training is advisable, and if so, what form it should take. This important point was unfortunately not taken up. Mr. Foss, in his paper, gave a clear lead in his suggestion that 'intuition' is a facility that should be recognized as a valuable ability in clinicians and interviewers, for example, and that persons of good intuition should be found and trained, over and above the need, already recognized, for the training of subjects to make finer discriminations of a situation with greater accuracy. Dr. Hopkinson suggested that observers should have certain valuable personal characteristics. They should have a social conscience, and give of their best, without needing to be encouraged by a knowledge of the trend of their results—indeed, they must not have any preconceived theory about the experiment on which they are asked to make judgments; otherwise their 'coefficient of involuntary mendacity' may cause deviations or over-compensation. Their social conscience should extend only to a desire for the success of the experiment, and not to an interest in its result. Personal characteristics may also influence the kind of criteria which form the basis of the judgment. Mr. Foss suggested that some subjects may work better with broad categories; others may prefer to exercise their abilities to make fine discriminations within narrow categories, and hence these people may be suitable for different experiments from the former. This is a valuable and interesting suggestion which may merit close attention by those engaged on the development of the discipline of subjective judgment experiments.

R. G. HOPKINSON

BOTANY OF FLAX

In introducing a meeting on the "Botany of Flax", held in Belfast on September 8 by Section K (Botany) of the British Association, Major G. O. Searle, of H.M. Norfolk Flax Establishment, referred to the importance of the flax plant as a major factor in building up the prosperity of Belfast and Northern Ireland in general. Although in Ernst Schilling's "Die Faserstoffe" more than nineteen hundred plant species are listed as being capable of yielding fibre of industrial use, the best of all—that is, *Linum* spp.—were utilized in the Middle East seven thousand years or more ago. It has been suggested by some that *Linum angustifolium* Huds. was the species first used for the manufacture of linen; but it is clear that for many centuries *Linum usitatissimum* L. has held the field; the taller fine-stemmed varieties are used for the production of fibre, and the shorter branching-varieties for linseed. The chief interest of linen flax lies in its fibre system and in the attempt to produce improved types by breeding, the quantity and quality of the fibre being the salient factors concerned. From 1880 onwards, flax growing in the British Isles has been mostly centred in Northern Ireland where, owing to the practice of 'dam retting', the seed is lost. Consequently, all sowing seed was imported from Russia and the Baltic countries or from Holland. Distinctive varieties as such were not available, and the brands of seed largely used were known as Riga or Pernau Crown. Often the seed was first imported into Holland, where it was grown once, and the produce exported to Northern Ireland as Riga Child or as Dutch seed under a merchant's brand. Some of these brands were exceptionally good; but they are not now obtainable owing to the changed conditions of flax culture in Russia and the Baltic countries since the Revolution of 1917.

Planned flax breeding was commenced in or about 1911 by the Department of Agriculture in Dublin and by Vargas Eyre at Wye College, Kent. Eyre had visited Russia and the Baltic countries in that year and had brought back seed from some of the best flax districts. These stocks were maintained in England until 1920, when they were taken to Northern Ireland and made available for the flax breeding programme commenced by the Linen Industry Research Association at Lambeg. It was then known that taller varieties of flax could be isolated by single-plant selection from existing commercial strains, and the early work was based on this knowledge. In order to short-circuit the lengthy procedure of bulking large numbers of pure line selections for field and mill trials, Searle and Davin developed a section-cutting, staining and fibre-measuring technique for assessing the likely value of selected plants. As a result of this work, the well-known series of Liral varieties of fibre flax were produced. Liral Monarch and Liral Crown were single-plant selections from a Dutch brand of seed; Liral Prince was a hybrid between a Dutch selection and one of the original Russian strains produced in 1911; Liral Dominion, a selection from imported Riga seed, has been extensively grown in Canada, while a short but more resistant variety, Liral Duke, has given satisfaction in Egypt when grown on irrigated land. Similar success attended the work carried out at the Plant Breeding Station of the Northern Ireland Ministry of Agriculture, where such popular varieties as Stormont Gossamer, Stormont Cirus and Stormont Motley have been produced. Some promising varieties have appeared on the Continent of Europe in recent years, but with the exception of Concurrent, a white-flowered flax which has been favoured by Continental growers for its standing and crop-yielding qualities, their popularity has not tended to be lasting.

Thus, during the past thirty years pure-line strains of flax have been produced which, according to the official trials, yield up to 50 per cent or more fibre per acre than the older commercial brands. Yet it is generally agreed both in Britain and on the Continent that the yields and grades of fibre are not so high as they were fifty years ago. The true explanation for this may lie in the inevitable decline in standards as fibre flax production slowly changed from a peasant handicraft to a semi-mechanized mill industry, and the outstanding problem is to devise ways and means for reversing this decline.

The future of flax breeding may be influenced by a study of yarn quality made in recent years by the Linen Industry Research Association. Here a significant correlation has been shown to exist between diameter and length of straw and spinning quality, indicating a relationship between fineness of straw and fineness of fibre. If it be assumed that fibre strands with fine ultimate fibres having thick walls and a small lumen are stronger than those having large ultimate fibres and a large lumen, then it would seem as if the search for strength may be linked with the search for fine quality, since the taller fine-stemmed varieties tend to have mor
and finer fibres and the thick-stemmed varietie
coarser fibres with a tendency to a large lumen
These findings may be put to the test in trials wit
the three new purple-flowered varieties, Norfolk Ear
Norfolk Prince and Norfolk Mandarin, which appea
to possess the characters required in the search fo
both quality and quantity of fibre.

In dealing with the question of seed health i
relation to flax, Prof. A. E. Muskett, of Queen'
University, Belfast, outlined the work carried out i
Northern Ireland for the purpose of providing tech
niques for the examination of seed for contaminatio
with fungal parasites. In the case of flax, this wor
culminated in the Ulster method for seed examinatio
as a routine procedure, and in proving the effective
ness of tetramethylthiuram disulphide as a flax-see
disinfectant. The disinfection of all sowing fibre fla
seed produced in the United Kingdom has no
become routine practice. The availability of th
Ulster method allowed a health survey to be made fo
flax seed produced throughout the United Kingdom
and the survey has now been carried out for a perio
of ten consecutive years, three to four thousand see
samples being examined each year. The results ma
be expressed as follows.

(1) (*a*) The incidence of the fungal seed-born
parasites *Colletotrichum linicola* Pethybr. and Laff
Polyspora lini Laff. and *Phoma* sp. is highly sig
nificant in the northern and western areas of th
United Kingdom. It is insignificant in the souther
and eastern areas. (*b*) The incidence of the fung
seed-borne parasite *Botrytis cinerea* Fr. may b
significant in flax seed produced in all areas of th
United Kingdom. Its incidence tends to be highe
in seed produced in some coastal areas.

(2) The results show clearly that seed contamina
tion occurs much more readily in the wetter an
cooler northern and western areas than in the dri
and warmer areas of the south and east, where
build-up of parasitic fungi, with the exception
Botrytis, has been observed over a period of ten year
Rainfall, in so far as it may encourage a continuous
humid atmosphere, is probably the major fact
leading up to seed contamination, with temperatu
conditions playing their part.

(3) Investigations over a ten-year period show th
the area to the south and east is well suited for t
production of supplies of healthy flax seed of goo
quality. The remainder of the country is not suitab
for seed production.

The results emerging from this survey show t
possibilities which might emerge from similar surve
carried out not only in the United Kingdom but al
on a world-wide basis with seeds of other agricultur
and horticultural crops, with the object of ensurin
supplies of seeds and planting stocks of proved go
health. Such work might be of very great benefit
the more backward regions where so much st
remains to be done to ensure more bountiful suppli
of food and raw materials.

In presenting a paper on the physiological specia
ization of *Melampsora lini* (Ehrenb.) Lev. by D
A. G. Arif (formerly a research student of Quee
University, Belfast, and now in India), Dr.
Colhoun, of Queen's University, said that studies
the reactions of sixteen differential flax varieties
pure cultures of *Melampsora lini*, the causal organis
of flax rust, collected in various parts of the Unit
Kingdom had resulted in the recognition of sixte

hysiological races of the parasite. Six of these races ave already been recorded in North America or urope; but the others are believed to have been itherto unrecorded. One new race was also isolated rom diseased flax sent from Pakistan. All the races ound occurring in England, Scotland or Wales have een recorded as occurring in Northern Ireland. All he fibre varieties of flax commonly grown in the ritish Isles are susceptible to all the British races f the fungus. The fibre varieties, Textilshchik, .S.S.R. No. 2, 1288/12 and Stakhanovets, developed or rust resistance in the U.S.S.R., as well as the rust-esistant variety Wada, bred in Australia, proved nmune to all the British races. These results show ubstantial agreement with those previously obtained 1 Northern Ireland for the reaction of these varieties 1 the field, with the exception that 1288/12 was usceptible in field trials in certain years. It is sug-osted that the difference between the results of field rials and those where known races of the fungus ere used for inoculation purposes may be attributed o more races being involved under field conditions han have yet been differentiated. These studies emonstrate that resistant varieties exist to provide he basis for the production of varieties which will ombine the quality of rust resistance to British races f the parasite and high yield of good-quality fibre.

The important problem of weed control in the flax rop was dealt with by Mr. K. Holly, of the Oxford Jnit of Experimental Agronomy, who emphasized he fact that flax cannot compete effectively with ggressive or perennial weeds. As it is the fibre in 1e stem of the flax plant which is the economic roduct, the use of selective herbicides for flax must e carefully studied for adverse effect on the straw s well as for effectiveness of weed control. In the ourse of experimental work with weedicides on rops in south and east England, sulphuric acid, mmonium sulphamate and ammonium thiocyanate ere quickly discarded because of the excessive amage caused. Although, at equivalent dosages, upric chloride had more adverse effect on flax than upric sulphate, from three to five times as much upric sulphate was needed to give a comparable egree of weed control. Dosages of cupric chloride f 10–20 lb./acre in 100 gallons of water had no dverse effect upon the yield of deseeded straw or cutched fibre at the 4–6-in. growth stage. Sodium initro-*o*-cresylate could be used at 6 lb./acre before 1e flax is 10 in. high without undue risk, and pproximately the same finding held for the sodium alt of 2-methyl-4-chlorophenoxyacetic acid used at lb./acre. Experiments on weed-free crops showed 1at the safety limits for cupric chloride and sodium initro-*o*-cresylate were small, whereas they appeared be greater for sodium methyl-chlorophenoxy-cetate. Since 1945 the work has been confined to comparison of the effectiveness of commercial rmulations of the sodium salts of 2-methyl-4-hlorophenoxyacetic acid and 2.4-dichlorophenoxy-cetic acid. The use of the sodium salt of the ethyl-choro compound at 1 lb./acre or less, with maximum resistance when the crop was 4–6 in. igh, was found to be safest for the variety Liral rince. With the advent of low-volume spraying, rther experiments showed that this method entailed greater risk of damage than medium- or high-volume pplications. The results of the work considered as whole suggest the recommendation of the use of dium methyl-chlorophenoxyacetate for weed con-ol in the flax crop in England. A dosage-rate of ¾ lb./acre should not be exceeded, and it should be applied between the cotyledon stage and the attainment of a crop height of 6 in. Low-volume spraying is probably undesirable. These findings are not altogether in keeping with those for other countries, and, although the reason for this is not clear, it may be concerned with the flax variety grown. Apart from weed control, the effect of synthetic growth regulators upon the anatomy of the flax straw and the consequent effect upon the yield of fibre suggests a most interesting field of study.

In opening the discussion, Mr. E. V. B. Wilson, of the Plant Breeding Division of the Ministry of Agriculture, Northern Ireland, suggested that selection in flax is not aided by any known correlation of desirable economic characters with any constant and easily observable morphological characters, and that none of the nine standard Russian flax varieties is satisfactory for all economic requirements. Unfortunately, this also holds for the United Kingdom, where work by plant pathologists in Northern Ireland has shown that the popular modern varieties of fibre flax are very susceptible to disease generally and probably more so than the older brands referred to by Major Searle. Mr. Wilson was of the opinion that breeding for disease resistance in flax and other crops is most essential and that the closest co-operation between the breeder and plant pathologist is highly desirable. Dr. J. Ramsbottom emphasized the sudden character changes liable to occur, particularly in the parasite, which may render a resistant host-plant susceptible. A good example of this, he said, is presented by the cereal rusts; but it is a problem which has to be faced. Prof. Muskett said that one hopeful aspect of the work on flax rust in Northern Ireland is the fact that one or more of the Russian flax varieties used has shown immunity to all the physiological strains of the parasite employed. With regard to resistance to flax wilt, Major Searle pointed out that tests made in Northern Ireland show the variety Norfolk Queen to be highly resistant to this disease.

Further discussion was debarred owing to the shortage of available time, but it is clear that the meeting did much to bring to light the difficulties facing the breeder of improved flax varieties, especially in view of the changing methods adopted in the linen industry. It also showed the desirability of producing seed in areas where the seed-borne disease factor is relatively unimportant, and for disease resistance to be taken into account by the breeder. Although a considerable advance has been made in the investigation of spraying with selective herbicides for weed control, the solution of this problem still awaits completion.

OBITUARIES

The Right Hon. Lord Robinson, O.B.E.

By the sudden death in Canada on September 5 of Lord Robinson of Kielder Forest and Adelaide, Great Britain has lost its foremost forester. An Australian by birth and early upbringing, he was one of the first of the Rhodes Scholars and seldom, indeed, can the Rhodes Foundation have made a better choice. His academic forestry knowledge was acquired under that wise old forester, Sir William Schlich, then professor at Oxford, of whom Robinson often spoke in later days with affection and respect.

A public servant since 1909, the whole of Robinson's long career was devoted to the cause of British forestry. The Forestry Commission, of which he was successively technical commissioner and chairman, owed its existence and policy very largely to his initiative and organizing ability.

Made a peer in 1947 in recognition of his outstanding services, he was the first forester to receive that honour. Characteristically, he took his title in part from the Border Forest of Kielder. The largest of the new forest blocks of his creating, it was also the one of which he was the most proud, partly perhaps because it exemplified the wisdom of his policy of proceeding step by step from the known to the unknown. It was not until the success of the pioneer afforestation at Smales in the Kielder area was reasonably assured that he agreed to the acquisition of the further large blocks which now comprise Kielder and the adjoining forests in the Border country.

Robinson's extensive tours of the forests in Great Britain and throughout the Commonwealth, as well as in many parts of Europe, reinforced by a remarkably retentive memory, gave him a uniquely wide experience of all branches of forestry. It was this wealth of experience which made him such a stimulating guide in the forest.

Robinson's approach to sylvicultural problems was essentially scientific, and although administrative work took up a large part of his time, his own contributions to our forestry knowledge were of no mean order. We owe to his fertile mind the highly original basis of the construction of our British yield tables which were built up from the measurements of 1,000 sample plots recorded in woodlands in the process of being felled during the First World War. Had it not been, too, for his foresight, all record of the rate of growth of these woods would have been irretrievably lost. Moreover, he was probably the first forester in any country to realize the importance of statistical lay-outs and analysis in field experimentation: in the early 1920's, he enlisted the aid of R. A. Fisher, then at Rothamsted, in order to ensure that the techniques being developed there for agricultural experiments were applied also to appropriate problems in forestry.

Lord Robinson's fine physique and handsome presence made him a conspicuous figure in any gathering. Inclined to be austere in the office, his reserve melted almost magically as soon as he got among his trees, when he was extremely good company. It was not until about two years ago, when an accident on one of his inspections of the Border country led to a serious illness, that he was obliged to curtail his outdoor activities to some extent; though even then he continued to cover an astonishing amount of ground, using a 'land rover' to get about over the forest tracks.

His many-sided gifts showed perhaps to the greatest advantage when he was presiding over a large meeting. Those who attended the Empire Forestry Conference held in South Africa in 1935 will long remember the tact and imperturbable good humour with which he conducted its affairs. It was while attending, as head of the British delegation, the Sixth Commonwealth Forestry Conference in Canada, that a sudden attack of pneumonia proved fatal. So at the height of his fame and almost at the end of his long and honourable career in the public service, a great man has departed; the nation is the poorer for his loss.

W. H. GUILLEBAUD

Sir Frederic Kenyon, G.B.E., K.C.B.

SIR FREDERIC KENYON, who died on August 23 gave forty-one of his eighty-nine years to the servic of the British Museum. For the last twenty-one o them he was director and principal librarian. Bor in 1863, the seventh of the fifteen children of Joh Robert Kenyon, Q.C., he laid the foundations of hi classical learning as a scholar of Winchester an of New College, Oxford. First-classes in Moderation and in *Literæ Humaniores* led to a fellowship a Magdalen in 1888, and a year later he won th Chancellor's English Essay prize. In 1889 he entere the Department of Manuscripts of the Britis Museum, where he devoted himself to the cataloguin of the extensive and increasing collection of papyri It was virtually an unworked field and a particular attractive one for a brilliant young scholar. He mad his name two years later by the discovery, publication and translation of Aristotle's lost treatise on th Athenian Constitution. The text of this was edite for the Berlin Academy in 1904 and for the Clarendo Press in 1920. Other discoveries among the literar papyri were the Mimes of Herodas, an unknow speech of Hyperides, and twenty odes of Bacchylides the latter from a roll acquired by the Museum i 1896. In 1899 appeared his well-known "Palæography of Greek Papyri". Other fruits of his scholarshi were the "Catalogue of Greek Papyri in the Britis Museum" (vol. 1, 1893; vol. 2, 1898; vol. 3, 1907 and "Facsimiles of Biblical Manuscripts in the Britis Museum", published in 1900. In addition to thes official labours, he published in 1895 "Our Bible an the Ancient Manuscripts", a classic in this field an many times reprinted.

In 1909 he was chosen to be director of the Britis Museum at an unprecedentedly early age and i preference to not a few colleagues of senior rank an of great eminence in their different fields. It was difficult situation calling for exceptional tact an wisdom. These qualities Kenyon possessed to th full, and with them urbanity, fairness, and administrative ability of the highest order. Never was th Museum more wisely and fairly governed; never ha its prestige been raised to a higher level. Classica studies had sharpened his critical faculties, enablin him to lay bare with penetrating clarity the essential of the most difficult problem. His capacity fo business, coupled with firmness and courtesy, mad him a model chairman, and he was at various period president of the British Academy, of the Helleni Society, of the Society of Antiquaries, and warde of Winchester College. In 1918 he was selected a adviser to the Imperial War Graves Commission.

After his retirement in 1930, Kenyon gave himsel largely to biblical studies, an early love, and t textual criticism in particular. He edited a series o biblical papyri which Mr. Chester Beatty had brough from Egypt, publishing the fruits of his labours i "Recent Developments in the Textual Criticism o the Greek Bible". To this work, produced in 1933 he added in 1948 "The Bible and Modern Scholarship", small in size, but weighty in content. A wor of more popular appeal but not less scholarly was hi "Books and Readers in Ancient Greece and Rome" which had appeared in 1932.

He was an honorary graduate of many universitie Many honours and decorations had fallen to him; bu it is probable that he prized none more highly tha the T.D. which marked his long connexion with th Territorial Army and with the Inns of Court Regimen in particular. Beginning the First World War as a company commander, he ended it as a lieutenant-colonel. Had he not chosen the path of scholarship, Kenyon might have been a soldier of distinction. He touched nothing which he did not adorn.

He married in 1891 Amy, daughter of Rowland Hunt. She died in 1938. Of his two daughters the elder is a well-known archæologist.

F. G. RENDALL

Dr. William McRae, C.I.E.

WILLIAM MCRAE was born in Scotland in 1878 and graduated in the University of Edinburgh, from which he later received the degree of D.Sc. He arrived in India on March 28, 1908, and joined the Agricultural Service as a mycologist at the Imperial Institute of Agricultural Research, Pusa, now the Indian Agricultural Research Institute, New Delhi. Dr. McRae's services were placed at the disposal of the Government of Madras with effect from January 1, 1910, for employment in the local Agricultural Department, where he served for nine years as Government mycologist and as the principal of the Agricultural College. During the period of his tenure in Madras he developed both mycological research and teaching. He successfully conducted campaigns against the serious disease of palms which is responsible for bud-rot. Earlier he also investigated the blister blight of tea which was responsible for heavy losses in tea plantations in Darjeeling, and published an extremely valuable bulletin on the subject, in which he described the control measures of this serious disease.

In 1920 Dr. McRae returned to Pusa as head of the Mycological Section of the Imperial Institute for Agricultural Research, a post which he held until the end of his service, except for intervals when he acted as agricultural adviser to the Government of India or as agricultural expert to the Indian Council of Agricultural Research. He was responsible for valuable investigations on the wilt disease of pigeon-pea, the mosaic disease of sugar-cane and also foot-rot of betel vine. He held the posts of joint director and that of director of the Imperial Institute of Agricultural Research, Pusa, in addition to his own duties, for short periods.

Dr. McRae made valuable contributions to the investigation of plant diseases and published more than twenty-one scientific papers. In recognition of his work he was appointed C.I.E. in 1934. He was placed on the retired list after more than twenty-five years service on June 23, 1934. He was one of the most energetic men in the Indian Agricultural Service, and besides being an able scientist he also had the reputation of a good administrator and a great disciplinarian, who spared no pains in the development of mycological research and kept up the standards so well established by Dr. E. J. (later Sir Edwin) Butler, whom he succeeded. In Dr. McRae's death on July 8, India has lost not only an outstanding scientist, but also a friend who will be held in esteem for a long time to come.

R. S. VASUDEVA

The Right Hon. Lord Macmillan, G.C.V.O.

MR. W. D. STURCH, secretary to the Royal Commission for the Exhibition of 1851, writes: "Lord Macmillan, who died on September 5, was chairman of the Board of Management of the Royal Commission for the Exhibition of 1851. He took a close personal interest in the Commissioners' scheme of science research scholarships, and those who were present at the 1851 Scholars' Centenary Dinner in 1951 will surely remember him with affectionate respect. His great humanity enabled him to see scientific achievement in a true perspective, and he was not afraid to remind a gathering of distinguished scientists that they were first and foremost human beings. He was intensely proud of the scientific record of the Commissioners' research scholars, and maintained his active interest in the work of the Royal Commission until the day of his death. Scientists may well join with those in many other walks of life in mourning the loss of a great friend".

WE regret to announce the following deaths:

Prof. C. B. Fawcett, emeritus professor of geography in the University of London (University College), on September 21, aged sixty-nine.

Mr. E. H. Godfrey, formerly chief of the Agricultural Branch, Dominion Bureau of Statistics, Canada, on September 22, aged ninety.

Prof. C. H. Lees, F.R.S., emeritus professor of physics in the University of London, formerly vice-principal of Queen Mary College, on September 25, aged eighty-eight.

NEWS and VIEWS

Emil Fischer (1852–1919)

EMIL FISCHER, who in his life-time exerted a profound influence on chemistry and chemists of his generation and whose discoveries in biochemistry are still yielding rich harvests, was born a century ago, on October 9, 1852, at Euskirchen in Rhenish Prussia. The son of a prosperous merchant, he was apprenticed for two years to his brother-in-law, a timber-merchant, on leaving school in 1869. His interest in experimental science led to his becoming a pupil of Friedrich August Kekulé at Bonn. After working as assistant to Adolf von Baeyer at Strasbourg and Munich, he held the chairs of chemistry at Erlangen and Wurzburg, and in 1892 succeeded August Wilhelm von Hofmann as professor of chemistry at Berlin. As early as 1875 he discovered phenylhydrazine, "the path-finder of carbohydrate chemistry", and described its reaction with the sugars to form osazones. He synthesized and formulated caffeine, xanthine, theobromine, glucose, fructose and veronal—the first of the barbiturates; developed a 'family tree' of gout, based on the purine nucleus; devised quantitative methods for isolating amino-acids, with which he prepared polypeptides; and, with Emil Abderhalden, did fundamental research on the specific action of enzymes. Keenly interested in the requirements of the chemical industry, he was instrumental in founding the Kaiser-Wilhelm Institut fur Chemie in 1912 and in the First World War organized Germany's chemical resources. A tremendous worker with a splendid memory, Fischer was idolized by his pupils and assistants, once they had accustomed themselves to his austere manner and to his exacting and critical methods. Elected a foreign member of the Royal Society in 1899 (he had been awarded the Davy Medal in 1890) and recipient of the Nobel Prize for Chemistry in 1902, he died during the night of July 14, 1919.

An Elizabethan Lodestone

THE National Maritime Museum, Greenwich, has recently been lent a lodestone reputed to have belonged to Sir Francis Drake and to have been given by him to Lawrence Kemeys. The lodestone is mentioned in an inventory of the possessions of the Kemeys family so far back as 1630, and has been handed down in the family to Lord Wharton, its present representative, by whose permission it is being exhibited in the Museum. It is approximately 1 in. by 1 in. by ¼ in. and is believed to have been reset in silver about 1700. The lodestone is of the type formerly carried by sea-captains when on long voyages in order to 'retouch' the compass needles when they became demagnetized. This one is extremely strong, having a magnetic moment of 1,900 c.g.s. units. Lawrence Kemeys came of the Kemeys, or Kemmeys, family of Cefn Mably House, Michaelstone, near Cardiff, and the earliest record usually quoted of him is his command of the *Gallego* under Sir Walter Raleigh during his voyage to Trinidad and up the Orinoco in 1595. He seems to have shared for a time Raleigh's imprisonment in the Tower of London in 1603, and was foremost in urging the undertaking of the latter's ill-fated expedition to the Orinoco of 1617.

Ramsay Centenary Exhibition

AN exhibition at the Science Museum, organized in collaboration with University College, London, marks the centenary of the birth of Sir William Ramsay (see p. 554); it will be open for three months. The Exhibition is divided into three main sections: the first will include books, documents, portraits and general biographical material. A large oil painting of Ramsay, made by Mark Milbanke in 1913, will form a fitting centre-piece. In the second group will be seen some of the original apparatus used by Ramsay and his collaborators. One of the earliest machines for obtaining liquid air, which was installed for Ramsay in 1898, has been re-erected for the exhibition. The third group illustrates the way in which the inert gases now serve our needs.

Incubation and Hatchery Practice

EVERY year in England and Wales about 100,000,000 poultry eggs are used for hatching purposes; of these, about 30 per cent fail to hatch. Failure to hatch may be due to unsatisfactory nutrition of the breeding flock or it may be due to some fault of the hatchery incubating the eggs. Whatever the cause, a 30 per cent loss represents a heavy charge on the poultry industry of Britain. Of equal or greater importance may be the effect of unsatisfactory hatching conditions on chicks which do survive any mismanagement at the hatchery. They may be affected to a degree which may adversely influence their ability as egg producers, and these poor-quality birds will remain an additional handicap on the poultry industry. To help poultry farmers the Ministry of Agriculture and Fisheries has produced a booklet which deals with the hatchery industry in considerable detail. The opening section describes the structure of the egg and the development of the embryo chick. Natural hatching and artificial incubation are then dealt with, and hatchery design, construction, hygiene and management are also described. A chart summarizes all the possible causes of hatching failure and how to avoid them, while the special requirements of turkey, duck and goose eggs are listed in an appendix. Copies of the bulletin may be obtained from H.M.S.O., price 1*s.* 10½*d.*

Detection of Insects in Grain

To reveal the extent to which a sample of grain is infested by insects and the nature of the insects concerned, a prolonged investigation in the laboratory which may take several weeks is required. But there is frequent need for some rapid method by which the presence or absence of living insects can be recognized, so that an immediate decision may be reached as to whether the grain in question is suitable for prolonged storage. Similarly, in stores receiving supplies from various sources, testing of incoming batches will prevent the addition of infested samples to the main stocks. The 'heating' of stored grain is a well-known sign of infestation, but a much more sensitive method for the detection of insects in grain is their production of carbon dioxide. At or below 15 per cent water content, the metabolism of the grain itself or of any micro-organisms it may contain is negligible in comparison with that found even with a minimal amount of insect infestation. R. W. Howe and T. A. Oxley, of the Pest Infestation Research Laboratory, Department of Scientific and Industrial Research, have written a concise statement of the principles and applications of the carbon dioxide method in a pamphlet entitled "Detection of Insects by their Carbon Dioxide Production" (pp. 20; London: H.M.S.O., 1952; 1*s.* net). This describes the apparatus required, the test procedure and the interpretation of results, and includes all the tables needed for the analysis.

Agriculture and Forestry

A STUDY of alluvial soils in north-west Germany from the point of view of combining alternate forestry and agriculture in a periodic or temporary agricultural use of forest land has been made by W. Wittich, and his conclusions have now been published in a brochure entitled "Landwirtschaftliche Zwischennutzung im Walde als Meliorationsmittel und Hilfe für die Ernährung" (temporary agricultural cropping on forest land as a means of soil improvement and as a supplementary source of foodstuffs) (Hannover: M. and H. Schaper, 1948) (see *Forestry Abstracts*, 13, No. 3; 1952. From the Commonwealth Forestry Bureau, Oxford). He reviews German, Austrian and Swiss literature on the subject, considering the varying characteristics of forest soils, the types of soil suitable for this purpose, the requirements of the agricultural crop plants that could be used, the practical management of such crops and the prospects for agricultural cropping on individual soil types, with main reference to the diluvial and alluvial soils of north-west Germany. He concludes that the widespread prejudice against this practice, one of the earliest practised by man, in part at least, is untenable; and he maintains that there are few soils on which agricultural use need be detrimental and many in which definite improvements could be achieved under proper treatment—for example, by the more intensive cultivation and fertilizing made economically possible by agricultural crops. This investigation, which is of great value, is really only a throw-back to the method of 'shifting cultivation' and should have a far wider application than north-west Germany. The old-type shifting cultivation is being utilized in India and Burma, under its Burmese name *taungya*, by the forest officer to produce new crops of some of the more valuable species of timber trees; the practice is applicable to Africa and elsewhere in the tropics. But Wittich's work introduces a further most promising step to the problem of a world shortage of food. For the permanent forest areas of the world, which for various reasons it is imperative to conserve, can nevertheless be used for the growing of food crops for a pre-arranged number of years at the end of a forest rotation, and then the land can be returned to permanent forest. Such a system should substantially increase the amount of land available at any one time for agriculture.

West African Gold Coast Timbers

A SMALL handbook of Gold Coast timbers was first published in 1941; it proved of great utility to officers of the Forest Department and others concerned and was soon out of print. Since then, considerable progress has been made both in the assessment of the forest resources of the country and in the development of the timber trade. To meet a growing demand, it was decided to publish a new edition, a work undertaken by D. Kinloch and W. A. Miller, of the Gold Coast Forest Department ("Gold Coast Timbers." Revised Edition. Pp. xii+39; Takaradi: Government Printing Department; 1*s*. 6*d*.). Thanks are accorded to the Director of the Princes Risborough Forest Products Laboratory for assistance. The closed-forest zone of the Gold Coast occupies approximately one-third of the entire territory and has an area of some 30,000 square miles. The remaining northern two-thirds consists of the savanna-forest zone, the forest resources of which are of purely domestic interest. The timber wealth of the country is concentrated in the closed-forest zone, of which it is estimated that some 16,000 square miles are still under forest; the remainder has been converted to agriculture, which continues to destroy an estimated 300 square miles of forest every year. The forest is not uniform in type throughout, there being a gradual transition from the south-west corner in a general north-easterly direction, and this transition is intimately connected with rainfall, though other local factors occur. Two types occur: the tropical semi-evergreen rain forest of the south-west corner, and the tropical mixed deciduous forest covering some ninety per cent or more of the whole zone. Sub-types are proposed, and a number of species described for which the booklet should be consulted. The information given in this new edition is almost entirely the work of the Forest Department and includes considerable additional data provided by enumeration surveys and records of the Forest Products Research Laboratory, Princes Risborough. War-time departmental experience in milling and utilization has also proved of great assistance.

Proceedings of the Bihar Academy of Agricultural Sciences

THE first number of the *Proceedings of the Bihar Academy of Agricultural Sciences* has now been published. In view of the importance of agriculture in India to-day, this new journal should be a great asset, for research results, particularly those relating to local crops and climatic conditions, must be available to all concerned if progress is to be made on sound scientific lines. The subjects discussed in the first number are very varied, but in each case the emphasis is laid on the practical aspect of the problem. Among the biological papers are those on inter-varietal hybridization in *Luffa acutangula* and its economic significance, and studies in the production of carbon dioxide in stored wheat infested by *Sitophilus granaria* L. and *S. oryzae* L. Soil and manurial problems are represented by a description of the Bihar soils, followed by an account of the results from a large number of field experiments carried out on cultivators' plots throughout the State. The benefit from the application of nitrogenous and phosphatic manures has been clearly demonstrated, and interest in their use so stimulated that appreciable increases in yields may be expected in many districts. The importance of statistics is evidently recognized, for the accuracy of field experiments is discussed in a further paper on the size and shape of plots in wheat trials. Three numbers of the journal will be published annually and those will be available free to members of the Academy; to others the annual subscription is Rs. 10. All communications should be addressed to the Secretary of the Academy, Agricultural Research Institute, P.O. Sabour (Bihar), India.

Newspaper Libraries in Great Britain

THE Library Association has published a pamphlet, entitled "Newspaper Libraries", by J. Lewis (No. 11 in the series; pp. 76; 1952. 7*s*., or 5*s*. to members), which outlines first the functions of such libraries in Great Britain and then describes the types of material contained in a newspaper library and the arrangement, classification and filing of such material. Some account is given of the news indexes maintained and indexing practice in newspaper libraries, of the methods used for the care and preservation of general and special material, and of the formal and informal co-operation which exists with other libraries. The pamphlet includes both a bibliography and index, and these facilitate reference to much information which may assist the technical or scientific librarian on occasion, as well as those whose needs are more general.

Manchester Museum: Annual Report for 1950–51

THE annual report of the Manchester Museum for the year ending July 1951 (pp. 28; from the Museum, Manchester; 1952) gives an account of continued progress in all departments. The housing of study and reserve collections has presented many problems, though by extensive movement of cupboards and cases a more orderly arrangement has been attained. The proper storage of collections involves classification, which is also an essential preliminary to cataloguing. One essential function of museums is research, and in this connexion it is interesting to note the large number of papers written by members of the staff during the year.

Fifth Empire Mining and Metallurgical Congress

THE fifth Empire Mining and Metallurgical Congress will be held in Australia during April 12–May 23, 1953, and afterwards in New Zealand. The Congress will afford an opportunity for mining engineers, metallurgists, scientific workers, engineers and others concerned with the mining and metallurgical industries to meet and discuss technical progress and problems, including the development of the mineral resources of the British Commonwealth of Nations. The programme will be divided into five parts: pre-sessional visit in Tasmania (April 12–19); inaugural meeting and other official functions, together with technical sessions, in Melbourne (April 20–25); visit to Canberra (April 26–27); further technical sessions in Sydney and tours in New South Wales, South Australia and, if desired, Queensland or Western Australia (April 28–May 23); journey to New Zealand inspecting coal and mineral fields in South Island, followed by a conference in Dunedin and then visits to North Island. The main section of the technical proceedings will consist of a series of volumes dealing in an analytical and comparative manner with Australian deposits and practices, as follows: (1) geology of Australian ore deposits; (2) mining methods; (3) milling methods; (4) extraction metallurgy—(*a*) ferrous, (*b*) non-ferrous; (5) miscellaneous and general; (6) coal; and (7) general handbook. In addition, literature describing equipment and practices in the various important mining centres will be available. Further information about the Congress can be obtained from the Secretary, Fifth Empire Mining and Metallurgical Congress, Osborne House, 399 Little Collins Street, Melbourne, Victoria.

International Fertility Association

In Rio de Janeiro last year, delegates from twelve nations founded a new medical society to be known as the International Fertility Association. The aims of this organization are fourfold: to study the problems of fertility and sterility in their broad implications; to stimulate scientific investigation and social awareness in the field of fertility and sterility; to standardize nomenclature, terminology, tests and evaluation of diagnostic methods and therapy throughout the world; and to hold regular international congresses in different parts of the world. The first World Congress on Fertility and Sterility, sponsored by the Association, will be held in conjunction with the American Society for the Study of Sterility, in New York City in May 1953. Further information can be obtained from the secretary-general of the Association, Dr. Carlos D. Guerrero, Miguel E. Schulz No. 19, Mexico, D. F., or from the associate secretary-general, Dr. Abner I. Weisman, 1160 Fifth Avenue, New York, N.Y.

Colonial Service: Recent Appointments

The following appointments in the Colonial Service have recently been announced: C. A. Collins (inspector of plants and produce, Gold Coast), agricultural officer, Gold Coast; R. G. Heath (chief field officer, Federation of Malaya), deputy director of agriculture, Federation of Malaya; J. D. Jameson (senior botanist, Uganda), senior research officer, Uganda; R. G. Sangster (senior assistant conservator of forests, Uganda), conservator of forests, Tanganyika; Sir James Kirkpatrick (game ranger, Kenya), senior game ranger, Kenya; Z. Wolak (assistant livestock officer, Nyasaland), livestock officer, Nyasaland; W. R. Asfour, agricultural superintendent, British Guiana; D. R. Goodrich, agricultural officer, Nigeria; K. W. Barker, pasture agronomist, Agricultural Department, Uganda; T. E. F. Neavind, agricultural officer, Uganda; J. E. Huddart and C. Walker, veterinary officers, Kenya; D. A. B. Llewelyn, scientific officer, East Africa High Commission.

Announcements

Mr. Harold James Page, principal of the Imperial College of Tropical Agriculture at Trinidad since January 1947 (see *Nature*, 158, 410; 1946), is resigning that appointment at the end of October in order to join the staff of the Food and Agriculture Organization of the United Nations.

The Lord President of the Council has appointed Sir Wallace Akers, a director of Imperial Chemical Industries, Ltd., and Sir Philip Johnson, a director of Hawthorn Leslie and Co., Ltd., and chairman of the Parsons and Marine Engineering Turbine Research and Development Association, to be members of the Advisory Council for Scientific and Industrial Research. Prof. P. I. Dee has retired from the Council on completion of his term of office. Sir Hugh Warren has resigned his membership of the Council because of the pressure of other duties.

The Council of the Institute of Metal Finishing announces that the Westinghouse Brake and Signal Co., Ltd., Prize is to be awarded to Mr. W. A. Marshall for his paper on "Non-Electrolytic Smoothing Treatment for Steel". The Johnson Matthey Silver Medal has not been awarded this year, no paper in the field covered by the terms of the award having been received. The Medal is offered for a paper dealing with any aspect of electrodeposition of precious metals.

Sir Frank Whittle has been awarded the Churchill Gold Medal of the Society of Engineers. The award has been approved by Mr. Winston Churchill, who is an honorary fellow of the Society, and is made "for the most noteworthy development in engineering or contribution to contemporary engineering".

The reconstruction of the war-damaged buildings of Bedford College for Women (University of London) will be celebrated at a meeting in the College on October 28 at 3.0 p.m. Addresses will be delivered by the Chancellor of the University and the Principal of the College; Queen Mary, patroness of the College, hopes to visit the College during the afternoon.

Prizes of value up to £150, with a maximum of three awards, are being offered for 1953 by the Council of the British Plastics Federation, as administrators of the Bowen (Cables and Plastics) Prize Fund. The awards will be made for papers on original investigations in engineering and/or physical problems relating to compression, transfer or injection moulding. Further information can be obtained from the General Manager of the British Plastics Federation, 47/48 Piccadilly, London, W.1, to whom contributions for the prizes must be submitted not later than July 31, 1953.

An international congress on medical librarianship will be held in London during July 1953, with Sir Cecil Wakeley, president of the Royal College of Surgeons of England, as honorary president. The congress will include formal sessions for reading and discussion of papers, visits to medical libraries and social functions, and also, it is hoped, an exhibition of medical books and periodicals and library equipment. All those actively engaged or interested in medical librarianship are invited to participate. Further information can be obtained from the Honorary Secretary, First International Congress on Medical Librarianship, c/o London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1.

GOVERNMENT RESEARCH IN AUSTRALIA

COMMONWEALTH SCIENTIFIC AND INDUSTRIAL RESEARCH ORGANIZATION

THE third annual report of the Commonwealth of Australia Scientific and Industrial Research Organization*, which now numbers fifteen divisions and expended more than £3 millions during the year, covers the year ended June 30, 1951, and again tresses the extent to which slow progress with the building projects handicaps the development of research programmes.

In spite of staff problems, the Division of Soils continued work on some fifteen soil surveys and a compilation of a manual of Australian soils was nearing completion. Chemical work on the basaltic soils from Lismore, New South Wales, was completed, studies on the availability to plants of copper and manganese continued, and an investigation into he ion exchange and *p*H relations of cation-dominant soils commenced. Studies on the stability of naturally occurring aggregates have shown that natural aggregation can be measured by a drop-shatter method, which has been used to help define the structure and consistency of soils of the Riverina and Abermusden districts.

During the year, 518 samples of seed and plant material, chiefly pasture and forage plants, were ntroduced from thirty-three countries for trial in Australia, and in the latter part of the year the active collection of plant materials in other countries was developed with the view of testing in Australia. Further trials have confirmed the value of *Lathyrus ochrus* as a green manure for use in vineyards especially on lighter soils, and of *Phaseolus* as grain egumes, while studies of flowering and seed-setting of introduced sunflower varieties continued. A section of plant genetics has been re-established and its work extended to include genetical and cytogenetical investigations of pasture species for Australian conditions, cereal problems not being pursued elsewhere, and problems in the resistance to disease of major vegetable crops such as the tomato and potato. The Plant Diseases Section has given special attention to the chemotherapeutic control of virus diseases, and investigations on the use of antibiotics for controlling plant diseases continued. Some six hundred further tests of native species were made for the presence of alkaloids, saponins, cyanogenetic glycosides and other chemical principles, and two hundred and fifty bulk samples were collected for more detailed examination. At Clare, Queensland, the two previous seasons investigations on the water requirements of tobacco showed that yield and quality were maintained over a wide range of treatments, and the effect of nitrogen-levels and rates of planting on quality was being investigated. Detailed studies of he nutritional requirements of subterranean clover are being continued under field, greenhouse and aboratory conditions; and other pasture investigations have included ecological studies on native and exotic pastures, nutrition and soil deficiencies, the use of pastures and maintenance of fertility. Weed investigations again indicated that plant-growth regulating substances alone offer no prospect of controlling established skeleton weed (*Chondrilla uncea*). At the Katherine Research Station, the limestone red soils of the Tipperary land system were being examined for determining the possibilities of agricultural development under dry-land conditions, while at the Kimberley Research Station agronomic and pasture problems under irrigation were being studied in co-operation with the Western Australia Department of Agriculture.

Research into problems of animal health and production at the McMaster Animal Health Laboratory, Sydney, included further studies with phenothiazine against internal parasites. Studies at the Veterinary Parasitology Laboratory, Yeerongpilly, Queensland, on the identification of the species of amphistomes infesting cattle have been completed, and evidence obtained that the 'Queensland itch' of horses is associated with hypersensitivity to the bites of sandflies (Ceratopogonidæ); protection by regular spraying with DDT was being investigated. Progress is reported in the development of the Poultry Research Centre at Werribee, Victoria, and studies of the vitamin A requirements of sheep, the effects of zinc and copper deficiency on the biochemical processes involved in phosphorylation within the tissues of plants, on carbohydrate metabolism, and on sheep feeding with particular reference to drought conditions continued, as well as on the influence of nutrition on the breeding performance of merino ewes.

Besides its work on the cattle tick, the Division of Entomology obtained very promising results in co-operative work on the control of the Argentine ant in Sydney and in Western Australia, which points to the possibility of complete eradication of the ant. The expected outbreak of the Australian plague locust did not materialize during 1950–51, and earlier work on the relation between trees and locust abundance was extended. A long-term experiment on the control with DDT of the pasture cockchafer, *Aphodius howitti* Hope, was concluded; but use of DDT against the red-legged earth mite in pastures also infected with the lucerne flea (*Sminthurus viridis* L.) is not recommended. Work on biological control has emphasized the importance of detailed attention to the flora associated with a weed, both to ascertain the extent to which other plants are likely to assist the insects and to determine the species likely to replace the weed. In the Wildlife Section, the work on the virus disease of rabbits, myxomatosis, was given priority, and the night-biting mosquito, *Culex annulirostris*, was shown to be the principal vector along the Murray main stream. Of poisons now in use, only sodium fluoroacetate showed promise for rabbit control.

Fisheries research at the Dunwich Field Station, Stradbroke Island, South Queensland, covered the distribution and movements of mullet in the estuarine and river phases of their history, the development of the oyster industry of Queensland, the distribution of prawns and preliminary work on lagoon fish-farming. The laboratory at Thursday Island, Torres Strait, was equipped and progress is reported in the study of plankton and the biology of pearl oysters. To extend the oceanographical work, preliminary plans were prepared for an oceanographical research vessel to be constructed in Great Britain. Studies on fouling by marine growths continued at various points, and this work has revealed the importation, on ships bottoms, of fouling organisms from other countries. A programme covering the biology and distribution of *Macrocystis* aims at giving a reliable estimate of the quantity of this seaweed in Australian waters, the seasonal and long-term fluctuations in yield of the seaweed and its products, and the method of regeneration of the plant.

* Parliament of the Commonwealth of Australia. Third Annual Report of the Commonwealth Scientific and Industrial Research Organization for the Year ending 30th June 1951. Pp. 167. (Canberra: Commonwealth Government Printer, 1952.) 9s. 6d.

Food research included a detailed study of the performance of refrigerated railcars with end bunkers and coolers, which led to the preparation of a statement of the principles governing the use of these vehicles for chilled beef transport. An account of the work on the evaluation of canning processes was published. Studies of the temperature relations of *Clostridium botulinium* and of the factors affecting the germination of heat-treated bacterial spores continued, while much work was done on the development of rapid laboratory and field methods for estimating the degree of fish spoilage. The longer storage life of dehydrated sugared fruit compared with ordinary dehydrated fruit has been confirmed, and varieties of fruit and vegetables were being tested for suitability for freezing.

The anatomical studies of timbers from Malaya, Borneo and New Guinea have proved of considerable value, and attention has also been paid to the factors causing the death of medullary ray and vertical parenchyma cells in sapwood-heartwood. Activity in the wood preservation field markedly increased; a survey of the causes of failure of preservative treatment of cross-arms was completed in Western Australia, Victoria and New South Wales, and a laboratory study of the toxicity and permanence of water-borne preservatives was commenced. Research on the properties and uses of building materials continued in the Division of Building Research; but the only new project was the preparation of a paper on the weathering and durability of building materials in the tropics for the International Building Research Congress held in London in September 1951.

Wool textile research was extended to cover the improvement of wool as a textile fibre and the reduction of costs of production of woollen, worsted and felted materials, but several years must elapse before the new laboratories are fully staffed with adequately trained research workers. Considerable interest has been displayed in the two processes recommended by the Organization for the recovery of wool from sheepskin pieces and broken skins. A suitable method has been developed for the alkaline hydrolysis of wool wax to wax alcohols and acids, and the study of the formation of fibres under natural conditions has been continued in the Division of Industrial Chemistry, where much attention has also been given to the study of wool wax and sugarcane wax. Steps were taken to provide a more comprehensive microanalytical service for scientific institutions and industry. Attention was also being given to analytical problems in connexion with the uranium ores of South Australia, the chemistry of alunite and its utilization in the production of potash fertilizers, the physiologically active alkaloidal principle of the Dwalganup strain of subterranean clover, and to liquid and vapour equilibrium concentrations of binary mixtures and their variation with temperature or pressure, in relation to plant design. A satisfactory method of concentrating topaz (used in ceramic ware) has been devised. The Section of Physical Metallurgy was concerned mainly with the metallography of alloys of titanium, gas surface reactions of titanium, and the influence of prolonged stress on lead alloys.

The work of the Division of Tribophysics continued on the same lines as in the previous year, but was still hindered by lack of space; and that of the Division of Metrology was largely determined by its statutory responsibilities for Commonwealth standards. The Division of Physics was also concerned with research designed to improve the accuracy of the methods of maintenance of standards, to increase the accuracy of measurement, the determination of properties of materials at extremely low temperatures and the study of the physical processes associated with the emission of radiation from the sun, including the development of new techniques for the study of the ionosphere and improved navigational aids under Australian conditions. The work of the Section of Meteorological Physics was consolidated and extended on the previous lines, including the prevention of frosts in orchards, the physics of rain and clouds, and the artificial formation of rain. In the Section of Mathematical Statistics two further centres have been established to provide direct assistance to divisions of the Organization in their experimental work. The Organization continues to co-operate with the Physics Department of the University of Melbourne in research on nuclear physics and cosmic rays under the direction of Prof. L. H. Martin.

AMERICAN SCIENTIFIC EQUIPMENT FOR BRITISH LABORATORIES

THE last report of the director of the Chemical Research Laboratory, Teddington, acknowledged the indebtedness of the Laboratory to the European Co-operation Administration of the United States for the supply of equipment unobtainable in Britain, including a Podbielniak Hyd-Robot self-recording low-temperature fractional-distillation unit, a Beckmann flame spectrophotometer and a multi-source unit for spectrographic work. A list of scientific equipment to the value of more than £350,000 made available in this way, chiefly to the Department of Scientific and Industrial Research, but also to some twenty-four other research institutions throughout the United Kingdom, has now been published*. The equipment, much of which is obtainable only in the United States, has been made available for a wide range of industries, and about three-quarters of i has already been received. It includes such diverse items as: an anderometer, enabling investigations to be made on precision bearings used in machine-tool spindles, etc., with the view of improving economy and quality of production; a compact surface analyser; a 'Falex' lubricant tester; multi-channel direct-reading spectrographs permitting the use of methods much in advance of existing rapid analytical technique; and a high-temperature dilatometer for research into moulding sand.

The National Physical Laboratory has been supplied with a set of valves for the construction of instruments for calibration in the frequency-range 2,660–10,000 Mc./s., a Carey recording spectrophotometer, a thallium boron-iodide prism, *K*-band klystron oscillators and crystal detectors, and with 'Fosterite' photoelastic material, as well as with nine Berkeley decimal electronic counting units. The Building Research Station has received two American explosive-actuated fastening tools as well as a portable strain-indicator, while American 'trafficators' with magnetic counters and accessories will assist the Road Research Laboratory in taking traffic censuses. The Fuel Research Station has received a centrifugal molecular still, a Brabender semi-automatic moisture tester, a temperature-compensated Worden gravity meter and deep-sounding gear; and a special disk of metals not available in Britain will assist the Gas Research Board in furthering its fluidized bed technique for gasifying coal. The development of heat pumps has been assisted by the supply of a special small thermostatic expansion-valve, and in connexion with the generation of electricity from wind power special transducer valves have been supplied for gust recorders.

---

* Issued by the Industrial Correspondent, Mutual Security Agency American Embassy, Grosvenor Square, London, W.1.

A Franz isodynamic separator has been supplied for the magnetic separation of minerals used in the atomic energy programme, and a small high-pressure pilot plant for catalytic flow-through experiments in organic synthesis. The work of the Shirley Institute has been facilitated by the installation of two Saco-Lowell speed frames and a ring frame, as well as a Scott serigraph for testing the strength of coarse yarns and light-weight fabrics. A special tensile testing instrument is being supplied to the Wool Industries Research Association, and a laboratory-type steamer, with pneumatically operated squeeze-rolls, to the Linen Industry Research Association. Other equipment supplied to research associations include the following: to the British Scientific Instrument Research Association, a Beckmann quartz spectrophotometer; the Motor Industry Research Association, a 'Stresscoat' equipment for stress analysis of crankshafts; the Pest Infestation Laboratory, American methyl bromide applicators; the Leather Manufacturers' Research Association, a Beckmann ultra-violet spectrophotometer; and to the British Paint, Colour and Varnish Manufacturers' Research Association, equipment to modernize a Perkin–Elmer spectrograph, a set of diffraction reference cards, and an automatic mixer for pigments and various media.

SURAMIN (BAYER 205) IN ANIMAL TISSUES

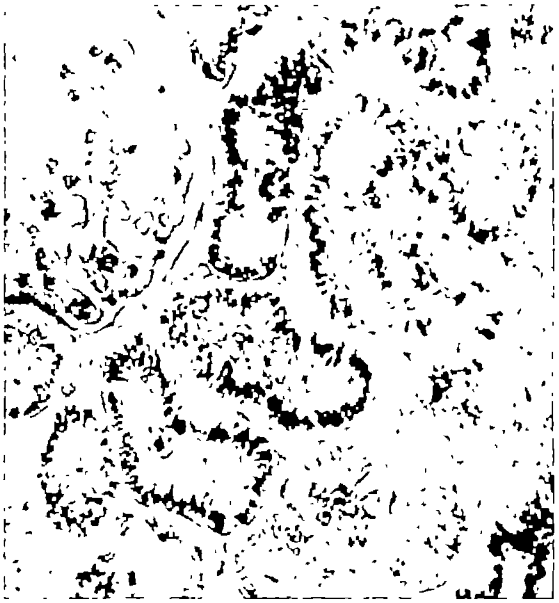
Demonstration of Bayer 205 (Suramin) in Tissues and its Cellular Distribution

THE purpose of our investigations was the elaboration of a histological method suitable for the study of the microscopic localization of suramin. Such a procedure seemed all the more desirable as this important chemotherapeutic drug is also, from a general theoretical point of view, an extremely interesting compound, owing to its being closely linked to proteins and its extremely long persistence in the organism (see refs. 1 and 2 for the literature).

Our experiments were based on the conception of combining the colourless sulphonic acid with a dye cation, thus rendering it visible. On the interaction of suramin and basic dyes in aqueous solution, coloured complexes are formed and, at a certain ratio of suramin to the dye, precipitation occurs, the same colloid chemical rules being valid as in the case of the interaction of acid and basic dyes having opposite electric charges. Among the quinone dyes with closed rings, several were found which could be also combined with the suramin present in the cells. Suramin could be 'stained' successfully with the following dyes: phenosafranin, cresyl blue, azure *B* (trimethylthionin). The best result was, however, obtained with methylene blue eosinate, which stained the cytoplasmic granules containing suramin deep violet; the nuclei were also faintly stained, and the counter staining of the eosine became visible too.

The essence of the specific staining technique is that a methyl alcoholic dye solution is used for fixing and staining simultaneously and, in contrast with routine histological methods, water is not employed, only organic solvents. A membrane cut from the connective tissue, omentum or mesentery is quickly spread out by means of pins on a slide, and, before drying, May–Grünwald stain is poured over it and left until it has nearly evaporated; then it is differentiated with continuous agitation in absolute ethyl alcohol for 20–30 sec.; the differentiation is interrupted with xylene, and the preparation is thoroughly washed in xylene and mounted in copaiva balsam. Smears of blood or exudate can be similarly stained as well as kidney tissue smears, in which the localization of the suramin in the nephron can be followed to great distances.

A second method is to place small pieces of organs in excess of May–Grunwald solution for about 10 hr. and then transfer them directly into benzene and embed them in paraffin; afterwards the sections are floated on slides, deparaffinized and mounted in copaiva balsam (see photograph).



Rat kidney 72 hr. after intravenous injection of 20 mgm. suramin. Granules containing suramin in the epithelial cells of the proximal tubular segment

Our investigations, with mice, rats and guinea pigs treated with suramin, furnished evidence that the drug is ingested by reticulo-endothelial cells in which it accumulates, forming granules in the course of a few days. Suramin could also be detected in fibrocytes and serosal epithelial cells. It appears in the course of the first few hours in the epithelial cells of the proximal tubules of the kidney, and may be stored there in large amounts, being visible even after one or two months, inducing occasionally a nephrosis. Thus suramin behaves in the organism similarly to the vital acid dyes (for example, trypan blue) or the chemotherapeutic arseno-benzene compounds[3]; however, in the elastic tissue of the vascular walls and in the fibrillar structures suramin could not be detected.

Suramin is not present in a free state in the intracellular granules, but in combination with a protein carrier. This view is supported by the fact that, on complete extraction of the dye from the preparation with methyl alcohol, the granules can be stained again. As suramin is very soluble in this solvent, this can only be interpreted by assuming that it is present in a protein linkage, which is in agreement with the fact that methyl alcohol is not capable of splitting off suramin from the protein[4].

In such staining, therefore, suramin plays the part of a mordant, being closely linked to the protein, reacting simultaneously with the basic dye and thus fixing it to the specific granules.

In interpreting the picture demonstrated in the kidney, the close combination between suramin and plasma proteins must be taken into consideration; it makes most unlikely the continuous penetration of the unbound drug through the glomeruli. In our opinion, the histological picture can be interpreted by assuming that a certain amount of protein escapes continuously through the glomeruli and is usually reabsorbed by the tubules. Thus if suramin is present in the plasma, the drug bound to the protein also gains access to the epithelial cells of the tubules and accumulates there. Suramin acts as a tracer showing the physiological path of the protein. We have also completed investigations showing that suramin is introduced into the reticulo-endothelial cells by a similar mechanism, because these cells also ingest proteins from their environment.

Visual Demonstration of Immune Reactions in Tissue

In the preceding communication, microtechnical methods have been reported which enable one to stain Bayer 205 (suramin) in cells so that the fate of the injected drug in the organism can be studied with histological preparations. The great affinity of suramin for proteins and its stability in the organism suggested the use of the drug as a label, thus making possible the demonstration by staining procedures of the further fate of proteins in normal and immune animals. It could be assumed that with suitable experimental conditions the *in vivo* reaction proceeding between the antigen and the antibody will be accessible for direct visual observation. It seemed that for this purpose the elicitation of the Arthus phenomenon with suramin-labelled protein would be the most appropriate.

Rabbits were injected intraperitoneally three times with 1 ml. of horse serum at intervals of two days; the test injection was carried out 5–15 days after the last sensitizing injection. At the test injection the rapid formation of a firm linkage between suramin and the proteins even at physiological *p*H and temperature was taken into consideration. The horse serum was mixed with an equal quantity of physiological saline solution containing 0·5, 0·8 or 1 per cent suramin, and 0·5 ml. was injected intracutaneously or subcutaneously in the dorsal or abdominal region. In animals sacrificed after 48–55 hr., a hæmorrhagic œdematous inflammation developed in an area 5–7 cm. in diameter at the site of the injection, which was absent in the similarly treated non-sensitized controls. Membranes from the subcutaneous connective tissue put on slides were stained with methylene blue eosinate dissolved in methanol in the manner described in our previous paper to demonstrate the suramin deposited in the tissues.

In the controls, the connective tissue is in a resting state exhibiting multipolar or spindle-shaped histiocytes with but few cytoplasmic granules containing suramin, and some round cells of monocyte character with a few specific granules. Undoubtedly the suramin was almost entirely resorbed together with the foreign protein from the local depot. In sensitized animals, on the contrary, it was retained in large quantities in the inflamed area and could be detected as accumulations in different types of cells. Not only the histiocytes, but also the capillary endothelial cells—the connexion of which was interrupted here and there—were crowded with granules containing suramin, and even the fibrocytes contained granules. However, the whole picture was dominated by the presence of numerous macrophages loaded with dark-coloured granules (Figs. 1 and 2).

The considerable storage observed at the site of the Arthus reaction cannot be ascribed to the enhanced capacity for phagocytosis of the cells of the animals pretreated with protein, since on injecting human serum mixed with suramin into rabbits sensitized with horse serum, this phenomenon could not be observed. The characteristic picture must therefore be due to specific serological causes. Local anaphylaxis is generally attributed to the combination of the antigen and the precipitin—mainly to circulating precipitin (cf. ref. 5)—occurring in the tissues. Hence we believe the explanation of the considerable storage of suramin is that these cells ingest the resulting antigen–antibody complexes and, with the large amount of protein, the bound suramin too.

Hitherto there has been inadequate explanation of the vigorous and specific inflammatory stimulus caused by protein injected into the tissues of the sensitized organism. We think that the characteristic

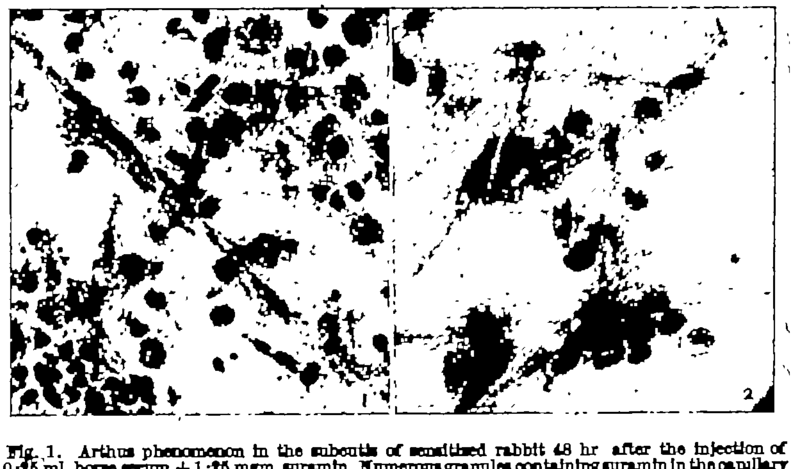


Fig. 1. Arthus phenomenon in the subcutis of sensitized rabbit 48 hr after the injection of 0·25 ml. horse serum + 1·25 mgm. suramin. Numerous granules containing suramin in the capillary endothelium and in the macrophages

Fig. 2. Control experiment, non-sensitized animal. In the body of resting histiocytes there are only a few granules containing suramin

histological picture of the Arthus phenomenon becomes much clearer by the actual demonstration that many cells of various types, including capillary endothelial cells, become heavily loaded with large masses of foreign and their own proteins.

It is a fundamental serological observation that foreign serum proteins and antibodies are eliminated at an accelerated rate from the blood stream as soon as the incubation period of immune body production ends; they persist only a very short time after sensitization in the circulating blood, and in the case of the subcutaneous application they become fixed locally. Undoubtedly the phenomenon described above plays a decisive part in local fixation. However, investigations in progress suggest that in general the rapid elimination of foreign proteins is due to the fact that the cells of the reticulo-endothelial system promptly ingest the antigen–antibody complexes owing to their colloid chemical properties.

THE DE HAAS – VAN ALPHEN EFFECT AT HIGH FIELDS

By Dr. D. SHOENBERG
Royal Society Mond Laboratory, Cambridge

RECENT experiments[1] have shown that the dependence of susceptibility on the periodic field originally discovered in bismuth by de Haas and van Alphen occurs also in many other metals at temperatures in the liquid helium range and magnetic fields up to about 15,000 gauss, such as are available in an ordinary electromagnet. According to the theory, however, the effect is detectable at such low fields only because of the anomalous values of the electronic parameters (effective masses and effective degeneracy parameter) characteristic of the complicated form of the Fermi surface in the metals concerned. For an ideal 'free electron gas' metal, the amplitude of the susceptibility oscillations should become appreciable only at much higher fields—of order 10^5 gauss; and the period should then be very small—of order 50 gauss or so. This is in agreement with the fact that no effect has yet been found by conventional techniques in metals such as gold, silver and copper. Experiments at higher fields are therefore of interest not only because they offer the possibility of discovering the effect in other metals and studying it in conditions where the theory can be tested most directly, but also because it would be of interest to study the effect at higher fields in metals for which it has already been found at lower fields. Comparison with theory suggests that in such metals only a very small proportion of the conduction electrons contribute to the effect at low fields, and it might be expected that short-period oscillations corresponding to the remainder of the electrons would occur at higher fields.

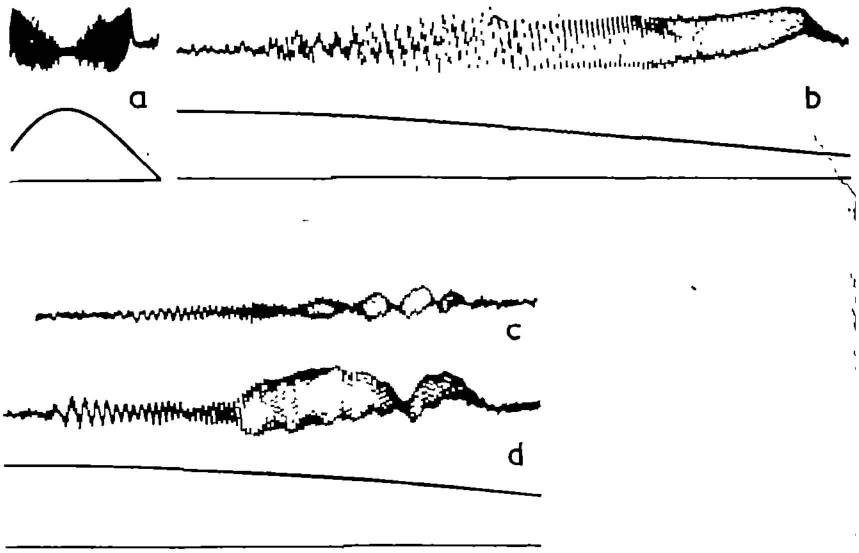
The usual method of studying the de Haas – van Alphen effect is to measure the torque on a single crystal suspended in a uniform magnetic field, but considerable difficulties are involved in extending this method to much higher fields. Such fields are most easily available in large water-cooled solenoids; but the geometry of such solenoids would make measurement of the torque awkward, and moreover it would be difficult to hold the field sufficiently stable—to 1 part in 10^4 or 10^5—to avoid smearing out oscillations of short period. It was therefore decided to try an entirely different technique of the type used by Kapitza, in which the high field is produced only momentarily, and to observe the oscillations of susceptibility by electromagnetic induction rather than by a mechanical method. The advantage of an induction method is that it measures the differential susceptibility $\mathrm{d}I/\mathrm{d}H$ rather than I/H, and if I/H oscillates rapidly with H the amplitude of $\mathrm{d}I/\mathrm{d}H$ may become large even though the amplitude of I/H is only of order 10^{-5}, since $|\mathrm{d}I/\mathrm{d}H| = \frac{2\pi H}{h}|I/H|$, where h is the period of the oscillations. With the development of cheap high-capacity condensers, it is a simple matter to produce fields of order 10^5 gauss in a fairly small coil, designed so that the field should be uniform to 1 part in 10^4 or 10^5 over the length of a short specimen ($\sim$ 5 mm.).

In the actual arrangement used, a condenser of capacity 1,000 µF. is discharged through a liquid-air cooled coil 12 cm. long, of external diameter 2·9 cm. and with an internal hole 0·8 cm. diameter, wound with 1,670 turns of 22 S.W.G. copper wire. When the condenser is charged to 1,750 volts, discharge produces a field rising to a maximum of $0{\cdot}9 \times 10^5$ gauss in about 3 m.sec., which then falls off to zero rather more slowly (the circuit is approximately critically damped). The solenoid fits closely around a Dewar vessel inside which are two 'pick-up' coils, each 1 cm. long and each wound with about 1,450 turns of 47 S.W.G. copper wire, connected in opposition so that the E.M.F. induced in the empty coils by the changing field is roughly zero. The specimen is placed in the region of uniform field of the solenoid at the centre of one of these coils, so that, if its magnetization varies, an E.M.F. proportional to $\mathrm{d}I/\mathrm{d}t$, and therefore to $\mathrm{d}I/\mathrm{d}H$ and $\mathrm{d}H/\mathrm{d}t$, is produced across the coils. This E.M.F. is amplified about 10^5 times and displayed on a cathode-ray oscilloscope triggered to give a single sweep when the discharge takes place. The exact moment of triggering and the duration of the single sweep can be varied so that any part of the curve can be examined in detail; the other beam of the cathode-ray oscilloscope is used to display the time variation of the solenoid current, that is, the field variation, and the picture is recorded photographically.

In order to try out the method and to develop the technique, the first experiments were made with tin, in which the de Haas – van Alphen effect has already been studied at low fields; using a single crystal with its tetragonal axis at about 70° to the field, the oscillations were successfully observed. Fig. *a* shows the oscillograph record at 1·2° K., using a sweep-time of about 10 m.sec. with a triggering delay time of about 1·5 m.sec.; the oscillations are unresolved and only the envelope can be seen as a kind of 'butterfly' pattern. As already mentioned, the observed amplitude is proportional to $\mathrm{d}H/\mathrm{d}t$ as well as to $\mathrm{d}I/\mathrm{d}H$, and so vanishes at the maximum of H. Fig. *b* is a composite picture of 1-m.sec. sweeps with various delays showing the oscillations in the right-hand half of the 'butterfly' resolved; the apparent frequency varies because equal intervals of H do not correspond to equal intervals of time, and also because the periodicity is uniform in $1/H$ rather than H. Analysis of the curves shows that the main period in $1/H$ is $2 \cdot 2 \times 10^{-7}$ gauss^{-1}; according to the theory, this period gives β/E_0, where β is an effective double Bohr magneton (that is, $e\hbar/mc$, where m is an effective electron mass) and E_0 is the degeneracy parameter. From the temperature variation of the amplitude, β is found to be $6 \cdot 5 \times 10^{-20}$ (that is, $m = 0 \cdot 28\ m_0$, where m_0 is the true electronic mass), so that $E_0 = 3 \times 10^{-13}$ erg (that is, T_0, the degeneracy temperature, is 2,200° K.). These values are in good accord with the results found from the low-field experiments, where it may be noted that the oscillations were at the limit of resolution of the torque method. It can be seen also that, superimposed on the main oscillations, there are other oscillations of about 4·5 times shorter period. It is probable that these arise from electrons which do not contribute to the effect at lower fields, but no detailed study of these higher-frequency oscillations has yet been made.

A serious difficulty in the general application of the method is the induction of eddy currents in the specimen by the varying magnetic field. These eddy currents can mask the effect in two ways. First, they cause the field in the interior of the specimen to lag behind that at its surface, and if the lag is too great the resulting non-uniformity of the field will smear out the oscillations; and secondly, the eddy currents may raise the temperature of the specimen sufficiently to reduce the amplitude of the de Haas - van Alphen effect. Both eddy current effects can be reduced by using specimens of small diameter, and are further reduced by the increase of resistance in a high magnetic field (fortunately, for many metals this increase is considerable at low temperatures). For oscillations with the relatively large period shown by the tin specimen, the 'smearing' effect due to non-uniformity is not serious except perhaps at fairly low fields, where dH/dt is large and the period in H is small. The seriousness of the rise of temperature was, however, clearly demonstrated by an experiment in which the tin crystal was contained in a glass envelope, and it was found that the amplitude was considerably reduced—presumably due to the poorer thermal contact with the bath. It is probable that the relaxation time for heat transfer is short compared with 1 m.sec., so that the instantaneous rise of temperature should be proportional to $(dH/dt)^2$, and the reduction of amplitude was indeed most marked where dH/dt was large. With the tin directly in contact with liquid helium, the heat transfer appeared to be adequate to prevent any serious rise of temperature. These considerations suggest that fo really high-frequency oscillations—such as are t be expected for a metal such as gold—it will b possible to observe the oscillations only very clos to the maximum of H, that is, where dH/dt i sufficiently small. The position is made more difficul also by the fact that in such metals as gold th increase of resistance with magnetic field is not nearl as great as with tin, so that the eddy current effect should be much greater. In fact, in one trial experi ment with a gold crystal, no oscillations greater tha the background noise were observed, and it is clea that the technique will have to be refined before i will work for metals approaching the ideal free electron model.

So far, the only success of the method, other tha indicating new high-frequency oscillations in tin, i the discovery of the de Haas - van Alphen effect i lead, for which no effect could be found at low field by the torque method. The results for two singl crystals are illustrated in Figs. c and d, and it can b seen that the period is appreciably shorter than fo the tin specimen. The 'beats' in the oscillations which are similar to those found in other metals a low fields, are presumably due to the presence o several nearly equal frequencies. Rough extrapola tion to low fields makes it plausible that the amplitud of the oscillations in lead would indeed have been to small to observe at 15,000 gauss by the torque method and even at somewhat higher fields the period woul have been too short to resolve. Analysis shows tha β/E_0 is $3 \cdot 9 \times 10^{-8}$ gauss^{-1} for crystal A with H a 20°, 73°, 81° to the cubic axes and $4 \cdot 5 \times 10^{-8}$ gauss for crystal B with H at 52°, 54°, 58° to the cubi axes; a third crystal, C, with H at 47°, 48°, 72 to the cubic axes, gave $\beta/E_0 = 4 \cdot 6 \times 10^{-8}$ gauss^{-1}, s it seems that β/E_0 is not very sensitive to the directio of H relative to the crystal axes. From the tempera



(a) Tin: 'butterfly' pattern showing the oscillations unresolved, 1·2° K.; peak field, $7 \cdot 0 \times 10^4$ gauss.
(b) Same as right-hand half of a but on expanded time-scale.
(c) Lead A, 1·2° K.; peak field, $8 \cdot 2 \times 10^4$ gauss, on expanded time-scale, as in b.
(d) Lead B, 1·2° K.; peak field $8 \cdot 2 \times 10^4$ gauss, on expanded time-scale, as in b.

The lower curves in a, b and d show the variation of the solenoid current measured from the horizontal base-line; c is arranged so that the same current curve applies as for d. In all the curves the time increases from left to right: a is 7 m.sec. long, b 3 m.sec., and c and d 2·4 m.sec. The slight ripples on the current curves are caused by a slight coupling between the two beams of the cathode-ray oscilloscope; the 'dot' pattern superimposed on the oscillations is due to a high-frequency modulation in the beam strength of the cathode-ray oscilloscope ture variation of the amplitude, rough estimates of β could be made for the three crystals, from which it was found that E_0 was about 8×10^{-13} erg (that is, T_0, the degeneracy temperature, was about 6,000° K.); the value of m/m_0 for crystal A was about 0·5. For crystal C, oscillations of roughly five times shorter period were visible near the maximum of H; it is interesting that this short period ($\beta/E_0 \sim 10^{-8}$ gauss^{-1}) approaches the order of magnitude to be expected for one free electron of normal mass per atom ($\beta/E_0 = 0{\cdot}3 \times 10^{-8}$ gauss^{-1}). The conditions for showing up these very short-period oscillations seem to be rather critical, and their behaviour has not yet been studied in detail. The very short period oscillations visible at the left in Fig. *d* are probably not due to the de Haas – van Alphen effect, but to some stray effect, since they appear to be of constant period in time rather than in $1/H$.

These preliminary experiments suggest that the method will be useful in giving new information about the electronic structure of metals, and it is planned to extend the work both to study in greater detail the characteristics of the de Haas – van Alphen effect at high fields in metals for which it is known to occur at low fields, and to look for the effect in other metals. The initiative in developing the condenser discharge method of producing high magnetic fields came from Mr. E. Laurmann before its application to the present problem suggested itself, and I owe him a great debt of gratitude for his success in making it work and for his assistance throughout these experiments. My thanks are due also to Dr. R. G. Chambers and Dr. D. V. Osborne for their valuable collaboration in designing and in part constructing the necessary electronic apparatus, without which the experiments could not have been carried out.

LUMINESCENCE OF AQUEOUS SOLUTIONS OF RADIOACTIVE ISOTOPES AND THE ČERENKOV EFFECT

By Dr. E. H. BELCHER

Physics Department, Royal Cancer Hospital, London, S.W.3

IN studies of liquid luminescent systems for use in scintillation counters, Mayneord and Belcher[1] observed a luminescence of low order in aqueous solutions of radioactive isotopes. Such an effect might be attributed to excitation of the substrate[2] or to the Čerenkov effect[3,4]. In view of the significance of these phenomena in the fields of radiation chemistry and biology, a quantitative study of the intensities of emission induced by beta-emitters of various energies has been made.

The emission intensities were measured with a 1-*P*-21 photomultiplier tube cooled with liquid nitrogen coupled to a linear amplifier (type 1008) and counting-rate meter (type 1037*A*). The radioactive solutions were contained in small cylindrical cells of 'Perspex', and of 'Dural' in which a 'Perspex' window formed one basal plane. The cells had a capacity of 6·25 ml. and were optically coupled to the photomultiplier by a short light guide. Quartz cells were at first used but proved unsatisfactory owing to fluorescence excited in the cell walls.

Experimental results for a number of beta- and beta–gamma emitting isotopes are tabulated below. For these studies, the amplifier was set at its maximum gain of 16,000, and the ratemeter discriminator at its minimum setting of 5 volts. The radioactive concentrations studied were chosen so that the counting-rates lay initially between 100 and 200 counts/second, but the rates shown in the table have been fully corrected for the small background effects and referred to a concentration of 1 μC./ml. With two exceptions, the activities of the solutions were measured in sub-standard liquid Geiger–Muller counters[5], themselves calibrated in terms of carbon ionization chamber gamma-measurements and defined solid angle beta-counting[6]. The exceptions were the low-energy beta-emitters calcium-45 and sulphur-35, which were standardized directly by defined solid-angle methods.

Studies of the amplitude distribution of the pulses at the input to the ratemeter indicated that they corresponded to the emission of single electrons at the photomultiplier cathode. It is thus permissible to treat the observed counting-rates as measures of the intensities of emission in the spectral range of the photomultiplier.

The classical theory of Frank and Tamm[7] implies a low energy limit for the Čerenkov effect satisfying the relationship $\beta = 1/n$, where β is the velocity of the emitting particles relative to that of light and n the refractive index of the medium. For electrons, this limit corresponds to 0·260 MeV. in water and 0·177 MeV. in 'Perspex'. The luminescence observed in solutions containing sulphur-35 and calcium-45 can thus be ascribed entirely to excitation processes in the substrate.

To a first approximation luminescent effects due to such processes may be assumed proportional to absorbed energy and thus, ignoring effects due to self-absorbed gamma-radiation and to the escape of electrons through the cell walls, to mean beta-particle energy. The expected contribution of excitation processes to the observed emission in the case of the higher-energy emitters studied can thus be estimated from the observed intensities for sulphur-35 and calcium-45. This contribution is found to represent only a small fraction (< 2 per cent) of the observed total intensities. The residuum after the estimated excitation intensity has been subtracted may be attributed to the Čerenkov effect.

Frank and Tamm's theory gives the following expression for the number dN of photons with wavelengths lying between λ_1 and λ_2 emitted in a length dl of track:

$$dN = 2\pi\alpha\left(\frac{1}{\lambda_2} - \frac{1}{\lambda_1}\right)\left(1 - \frac{1}{\beta^2 n^2}\right) dl, \qquad (1)$$

where $\alpha = \dfrac{2\pi e^2}{hc}$. Hence, the total number N_E of photons within these limits emitted along the track of a particle of initial energy E brought to rest within the medium is given by

$$N_E = 2\pi\alpha\left(\frac{1}{\lambda_2} - \frac{1}{\lambda_1}\right)\int_{\beta n > 1}\left(1 - \frac{1}{\beta^2 n^2}\right) dl. \qquad (2)$$

For the spectral range of the photomultiplier ($\lambda_1 = 7000$ A., $\lambda_2 = 3000$ A.) equation (2) reduces to

$$N_E = 874 \int_{\beta n > 1}\left(1 - \frac{1}{\beta^2 n^2}\right) dl. \qquad (3)$$

EXPERIMENTAL RESULTS FOR BETA- AND BETA–GAMMA EMITTING NUCLEAR SPECIES IN AQUEOUS SOLUTION

Nuclear species	Chemical form	Radiations		Observed counting-rate for 1 μC./ml. (corrected for background effects)		Remarks

Exp. values: ○, 'Perspex' cell; ●, 'Dural' cell

This integral can be evaluated graphically from a knowledge of the range–energy function for electrons in the medium. In the case of a beta-emitting radioisotope, the energy distribution of the emitted beta-particles must be taken into account. If P_E is the probability of release of a beta-particle with energy between the limits E and $(E + dE)$, then the average total intensity I_β of Čerenkov emission per beta-particle is given by

$$I_\beta = \int^{E_{\text{max.}}} P_E \,.\, N_E \,.\, dE. \qquad (4)$$

In the accompanying figure, the relative values of the observed intensities, corrected as described above for excitation effects and also for escape of electrons from the medium, for self-absorbed gamma radiation, and for Čerenkov emission in the 'Perspex' walls, are compared with the theoretical intensities per beta-particle obtained from equation (4), the intensities being plotted against maximum beta-particle energy. The corrections were small except in the case of the energetic gamma-emitters iron-59 and cobalt-60. The observed relative intensities have been superimposed on the calculated intensity–energy function so that exact agreement is obtained for gold-198 solutions in 'Perspex' cells. The relative values for the other nuclear species studied show good agreement with Frank and Tamm's theory, though there is some evidence of a systematic deviation at energies near the threshold. Similar deviations have been reported by Wyckoff and Henderson[8] for the angular distribution of emission induced by mono-energetic electrons in mica films.

Equation (3) predicts the release of some 90 photons between 3000 A. and 7000 A. by a single 1-MeV. electron brought to rest in an aqueous medium. The observed intensities were in general agreement with this value, although uncertainties in the detection efficiency of the measuring system did not permit its accurate confirmation. A more detailed account of this work will be published at a later date.

I wish to record my indebtedness to Prof. W. V. Mayneord, director of the Physics Department, for his interest and encouragement throughout these studies. Acknowledgment is also due to the Medical Research Council which supported the investigation.

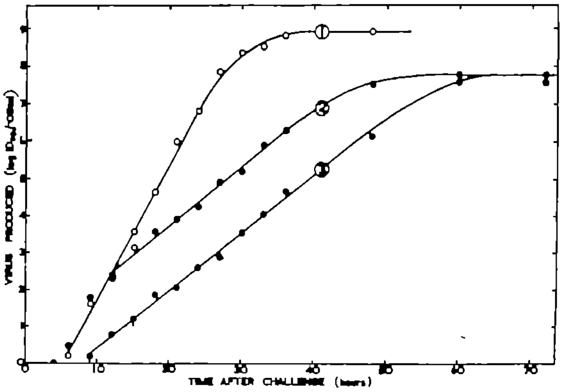
Multiplication of Influenza Virus under Conditions of Interference

ALTHOUGH it is well established that inactivated viral particles interfere with the multiplication of active virus, the intimate mechanism of the phenomenon is unknown. The fundamental experiments, confined to the comparison of final yields, did not show whether the observed depression resulted from complete incapacitation of some cells, from an overall owering of cellular output, or merely from the slowing-down of the process. Similarly, it is not clear whether the challenging inoculum enters all cells at random, or only those which have the potential ability to yield virus. Some of these questions have been answered by the kinetic study of interference, and the results will be reported in full elsewhere; here we propose to point out some peculiarities of the growth curves, as they reveal possible pitfalls in the planning and interpretation of interference experiments.

Heat-inactivated *LEE* (influenza *B*) virus was used as interfering agent in 0·5-ml. volumes injected allantoically into eleven-day eggs. The challenging dose, 100 ID_{50} of *MEL* (influenza *A*) virus, followed after 45 min.; in later experiments, for reasons set out below, a second group was included with 24 hr. between the two inoculations. The group of control eggs received only the challenging inoculum of *MEL* virus. At intervals, 0·05-ml. samples of allantoic fluid were withdrawn and titrated for infectivity.

The group of controls (curve 1) behaved as would be expected from earlier reports in the literature[1]; the titre rose at a steady logarithmic rate between the sixth and twenty-seventh hour, and then levelled out at a maximum of $10^{9\cdot 20}$ ID_{50} per ml. Curve 2 the group challenged 45 min. after administration of the interfering inoculum) is remarkable for the change in slope after the fourteenth hour. This means that, in spite of the interfering dose, the first cycle of multiplication was in every respect the same as in normal eggs, that is, either interference had not yet been established or, if so, the challenging inoculum multiplied only in cells not affected. To clear up this point, the interval between the administration of interfering and challenging doses was increased to 24 hr. (curve 3). This curve has a uniform slope (1·43), the same as that of curve 2 from the fifteenth hour onwards (1·45), and also reaches the same maximum ($10^{8\cdot 85}$ ID_{50}/ml.), though 12 hr. later. The difference between curves 2 and 3 suggests that the establishment of interference—as opposed to the adsorption of virus[2]—is not instantaneous; and in the special case when active virus closely follows inactive, the high final yield after large challenging inocula which could exhaust all available cells within two cycles of multiplication might appear as the 'overcoming of interference'[3], though, in fact, it is but the 'by-passing of interference'. With an appropriate interval between the two inoculations, the final yield is independent of the challenge dose[3,4].



Curve 1: 100 ID_{50} of active *MEL* (*A*) virus; curve 2: 400 agglutinating doses of heated *LEE* (*B*) virus followed after 45 min. by 100 ID_{50} of active *MEL* (*A*) virus; curve 3: 400 agglutinating doses of heated *LEE* (*B*) virus followed after 24 hr. by 100 ID_{50} of active *MEL* (*A*) virus.

Infectivity titrations were done in 3·16- or 10-fold steps, using 5–10 eggs per dilution. The points of curves 1 and 2 are the geometric means of four, those of curve 3 of three, replicate experiments

Comparison of curves 1 and 3 shows that a lower slope is as characteristic of the growth-curve during interference as is the lower final yield. By failing to reckon with this (that is, if experiments are terminated as is usual after 48 hr.) an exaggerated picture might be obtained, as smaller challenging inocula might not have reached maximum titres at the time of harvesting. It is interesting to note that a log 1·15 reduction of yield goes with a log 0·205 reduction of slope, and from this the average length of the multiplication cycle works out as 1·15/0·205 = 5·6 hr. Though this is considerably lower than the value given in the literature (release of virus starting at 6 hr. and not completed before 10 hr.), it seems significant that the hitherto available estimates of burst size and length of cycle are incompatible with the observed growth-curves[1], while the above value fits them all.

Macrophages in the Periodontal Tissues of Rats' Incisor Teeth

IN a previous communication[1], it was reported that the incisor teeth of rats kept on a poor South African diet developed signs of deficiency of vitamin A and of calcium. In addition, the sub-enamel tissues contained a large number of macrophages laden with highly refractile orange-coloured granules, as has also been described in vitamin E deficiency by Granados, Mason and Dam[2]. The present communication records investigations of the granular ameloblasts and macrophages of normal and experimental rats' upper incisor teeth.

The material examined was from normal rats and those with acute or healing rickets or suffering from deficiency of vitamin A or E. Preparations of enamel organs were dissected from teeth which had been fixed in formol-saline but not decalcified. These were mounted as smears or frozen sections. In addition, central longitudinal sections of ground or decalcified tissues were examined. The ground sections were impregnated with acrylic after bulk staining with alcoholic borax-carmine and were ground to a thickness of about 15 μ, using the technique already described[3]. With such thin sections, histological details were well seen. The decalcified sections were treated, after fixation, with 5 per cent nitric acid in formol-saline for about five days, and were afterwards processed in the usual way.

It was found that decalcification of the tissues often altered the appearance and histochemistry of the granules in an unpredictable way, so the decalcified sections were chiefly used for studying the cytology and situation of the macrophages.

Refractile orange granules were found in the granular ameloblasts and also in macrophages situated under the enamel organ of undecalcified preparations. The granular ameloblasts are found just behind the area where pigment is first deposited on the enamel[4]. The granules in both situations had the same histochemical properties. They did not stain with hæmatoxylin and eosin, basic fuchsin or osmic acid; they were not acid-fast, did not fluoresce in ultra-violet light nor were they doubly refractile. They stained intensely for iron and also with ammoniacal silver. In sections where the pigmented enamel had remained in strips, this structure gave the same reactions. The various experimental procedures did not alter these reactions of the granules and pigmented enamel, except that the iron reaction was greatly reduced or absent in the later stages of vitamin E deficiency. From the above evidence it would appear that the granular material in the ameloblasts and macrophages and the pigment of the enamel were identical or very similar chemically. Stein and Boyle[5] considered the pigmented enamel layer to be a melanin, while Dam and Granados[6] stated that it was not a lipochrome, porphyrin or melanin.

After decalcification with nitric acid, the character of the granules sometimes changed; those in the ameloblasts might disappear, while those in the macrophages might lose their refractile appearance and positive iron reaction, stain grey with hæmatoxylin and intensely with basic fuchsin. Ground sections made from the corresponding opposite tooth invariably showed orange refractile granules in both types of cells.

Macrophages were only found where the enamel organ had normally retrogressed, in the incisal quarter of the tooth, or where it had atrophied prematurely owing to the experimental procedures used. They appeared to originate from fibrocytes in contact with the enamel. These spindle-shaped cells contained small amounts of refractile material which seemed to come from the pigmented layer of the enamel. As they receded from the enamel, these cells grew in size until they became large oval cells with a deeply stained round, oval or indented nucleus. The refractile material in their cytoplasm coalesced by a proces of coacervation into large granules.

In normal teeth a few rows of macrophages wer found in the sub-enamel organ tissue between th crest of the labial alveolar bone and the gingiva margin. In experimental conditions, when the ename organ had retrogressed prematurely or atrophied macrophages were found much farther back, lyin under the area of atrophy, while in vitamin A-, an especially vitamin E-, deficiency, when almost th entire enamel organ was atrophied[7], a great numbe of them would be found under the atrophied organ It was noted in several teeth dissected from vitami E-deficient animals that, whereas the enamel wa almost entirely white, an area of pigmentation wa to be seen at the extreme formative end. The sam was seen in ground sections.

It appears from the above observations that th macrophages or their precursors remove the pigment in part or wholly, from the enamel when it is no covered with functional ameloblasts. In vitamin A and E-deficiency, so much of the enamel organ ha atrophied that the whole of the pigment may b removed. In the vitamin E-deficient animals studied which had been on the diet about sixty days, th granules in the ameloblasts and those in the macrophages still contained iron. Possibly at a later stag these granules became iron-free, as would be suggeste by the work of Dam and Granados[6,8]. It is ver unlikely that the macrophage pigment in vitamin E deficiency is ceroid, as has been suggested by Dam Granados and Maltesen[8].

I am indebted to Profs. J. Gillman and J. G Thomson for helpful information. The expenses o this work were met by grants from the South Africa Council for Scientific and Industrial Research.

Localization of Erythemal Processes caused by Ultra-Violet Light in Human Skin

SINCE the fundamental experiments of Hausser an Vahle[1], in 1922, it has been known that two wavelength regions of the ultra-violet spectrum, namely near 297 mμ and about 250 mμ, have maximu efficiency in producing erythema in human skin These regions are separated by a region near 280 m with small erythemal activity. The explanation fo this action spectrum has been sought in the screeni function of the superficially situated horny laye which, as a protein with aromatic compounds, ha a maximum light absorption[2] near 280 mμ.

Radiation experiments with a quartz spectrogra and the interpretation of the results of reflexio xperiments prove that it is converted into methane ery rapidly indeed.

Further experiments are in progress, particularly n the importance of hydrogen gas as a source of umen methane. They will be published in detail lsewhere.

Use of High Molecular Weight Solutes in the Study of Isolated Intracellular Structures

During a study of red algal plastids ('rhodoplasts') *in vitro*, some facts came to light which may have general interest in a study of isolated cell components. Sugars, such as sucrose, are the substances commonly used for the maintenance of the osmotic environment for isolated cellular components[1].

The red algal plastids are apparently permeable to low molecular weight solutes such as sucrose and potassium chloride, but not to higher molecular weight solutes such as some polyethylene glycols, dextrin and egg albumin. This result is not surprising in view of the colloidal nature of the cytoplasm and the obvious necessity for small molecules to pass rapidly into or out of the plastids. It is suggested that mitochondria and nuclei may be found to have similar properties in many organisms. We may note the ineffectiveness of sucrose in preserving the form of mitochondria from tobacco leaves[2] and pea seedlings[3], and of the pigment granules from sea urchin eggs[4].

The plastids most used in this study were those of *Griffithsia pacifica* Kylin, because of the large size and fragility of the cells. If the plants are crushed in distilled water, sea water (concentrated up to three-fold), potassium chloride (up to 1·5 *M*) or sucrose (up to 2 *M*), the plastids swell and lose their red pigment to the medium within a few minutes, and the suspension changes colour from a dark red to a brilliant orange. This colour change is due to the fluorescence of the phycoerythrin when released from the plastids. Under the microscope, the plastids round up, gradually swell, and often become vacuolated; the phycoerythrin dissolves in the vacuole, and the chlorophyll and carotenoids are in a misshapen mass at one side. The vacuolar membrane appears colourless. Under some conditions, vacuoles may not form. In striking contrast to this is the behaviour in 'Carbowax 4000' [5] (polyethylene glycol, $HOCH_2(CH_2OCH_2)_nCH_2OH$, mol. weight about 2,400 [6]). With this at a concentration of 0·8 gm. per ml. of 0·1 *M* buffer, the plastids appear as they do in the cell and are smooth and homogeneous. In a concentration of 0·4 gm./ml. the plastids round up, but remain smooth and homogeneous. In either of these the plastid form remains unchanged for hours or days at room temperature or in a refrigerator; the phycoerythrin remains in the plastids and does not become fluorescent. A similar picture is given with 'Carbowax 6000' (higher mol. weight), dextrin or egg albumin in sufficient concentrations. But 'Carbowax 1540' (average mol. weight about 1,500) and lower molecular weight polyethylene glycols gave only temporary protection when compared at the same percentage concentrations. Experiments with *Antithamnion uncinatum* Gardn. and *Corallina* spp. gave similar results with respect to fluorescence. Due to deviations from van't Hoff's law, in concentrated solutions of 'Carbowaxes', dextrins and proteins, molarities are meaningless with respect to osmotic pressures, but 0·4 gm. 'Carbowax 4000' plus 1 ml. 0·1 *M* phosphate buffer was found to be about isotonic with intact *Griffithsia* cells.

That the observations reported above are due to osmotic effects is indicated by the effectiveness of widely different substances and the ineffectiveness of similar substances of lower molecular weight. Dialysis of 'Carbowax 4000' did not alter the above results. By successively decreasing the concentrations of 'Carbowax 4000', sucrose and sea water, minimum values of 20 per cent, *M*/8, and 2/3 normal concentration, respectively, were found which just prevented fluorescence and the rounding up of *Griffithsia* plastids. Tests of some other high molecular weight substances (algin, gelatin, methyl cellulose) were unsuccessful, apparently due to low solubility, while a sample of 'polyglucose' supplied by the U.S. National Research Council (average mol. weight about 2,000), although very soluble, was also ineffective. The polyethylene glycols have the great advantages of controllable molecular weight, high solubility and chemical inertness[5].

Electrometric measurement of the Hill reaction (photolysis of water using ferricyanide at the oxidant) have shown that *Griffithsia*, *Antithamnion* and *Corallina* plastids are very active in solutions of 'Carbowax 4000'; but the activity is greatly reduced or eliminated in dilute buffer alone. Tests were also made with several green plants. *Nitella* and *Elodea* chloroplasts maintained activity in the Hill reaction longer in 'Carbowax 4000' than in sucrose, while buffer alone was very injurious. Chloroplasts of several land plants (spinach, New Zealand spinach, tobacco), on the other hand, showed *lower* initial activities in 'Carbowax 4000' compared to sucrose, although New Zealand spinach and tobacco, at least, seemed to show microscopically more normal chloroplasts in the 'Carbowax'. Of these, only tobacco revealed any preservative effect of the 'Carbowax' when chloroplast suspensions were kept overnight at about 15°, the activity in sucrose decreasing ten-fold compared to three-fold in 'Carbowax'. *Bryopsis corticulans* Setch. also failed to show any beneficial effect of 'Carbowax' on the Hill reaction. The chloroplasts of this species swell only slowly in sea water or sucrose.

Work on the red algal plastids is still in progress and will be reported in greater detail later. This work was done under contract with the U.S. Office of Naval Research (*ONR* 414(00)). We are indebted to Dr. A. R. Moore and the Carbide and Carbon Chemicals Co. for supplying samples of 'Carbowaxes'.

Since the above work was completed, two papers by H. G. Callan have come to our attention[7]; he reports that nuclei from amphibian oocytes are permeable to low molecular weight solutes (up to tetranucleotides), but not to egg albumin, glycogen, acacia or soluble celluloses.

Sodium Acetate Agar as a Sporulation Medium for Yeast

THE formation of adequate numbers of 4-spored asci in yeasts is essential for genetical analysis, and, as spore viability decreases with age, it is advisable to induce rapid sporulation and transfer spores as soon as possible to a nutrient medium containing sugar.

Adams[1] has obtained high yields of spores with baker's yeast by incubating for seven days on a sporulation medium consisting of 0·14 per cent anhydrous sodium acetate, 0·04 per cent dextrose and 2 per cent agar. I have tested various modifications of this formula on American 'Yeast Foam' (a strain of *Saccharomyces cerevisiae*); incubation of sporulation media, after inoculation, was restricted to 40–48 hr. at 25° C. On a medium consisting of 0·3–0·5 per cent anhydrous sodium acetate + 1·5 per cent agar, *p*H 6·5–7·0 (sterilized for 20 min. at 122° C.), 40 per cent sporulation (percentage of cells forming asci) has been recorded several times. Although sporulation is inferior to that recorded for the same yeast by Hartelius and Ditlevsen[2] on gypsum (45 per cent) and cement (56 per cent), this is more than compensated by a higher proportion of 4-spored asci: on the acetate medium, these constitute 12 per cent of the cell population (mean of twelve trials) compared with 8 per cent on cement[2] and 4 per cent on gypsum[2].

Trials with other yeasts have shown that sodium acetate agar, prepared as above, gives consistently high numbers of 4-spored asci after 48 hr. Thus, in several hybrids, up to 50 per cent of the cells have produced 4-spored asci. The introduction of this sporulation medium, therefore, should prove of great value in genetical studies on yeast.

Coupling Azo Dye Methods for Histochemical Demonstration of Alkaline Phosphatase

THE coupling azo dye methods of Menten, Junge and Green[1], and of Manheimer and Seligman[2], have generally been found insensitive and unsatisfactory for the demonstration of alkaline phosphatase. The recent improvement of the method by Gomori[3], using sodium α-naphthyl phosphate, has overcome some of their disabilities. We have confirmed that this substrate is the best available, but find that with acetone-fixed paraffin sections the method is still insensitive and useful only for the demonstration of sites of high enzyme activity.

If brief cold formalin fixation (4°, 8–16 hr.) is substituted, and 10–15-μ frozen sections, the method becomes as sensitive as any so far published. Preservation of enzyme is good, fixation artefacts few and enzyme diffusion negligible. Nuclear staining, reported absent by Gomori[3] and Novikoff[4], we have often observed in paraffin but never in frozen sections. Using cold formalin-fixed sections, the most important single factor becomes the choice of a suitable diazonium salt for coupling at an alkaline *p*H.

We have tested a number of stable diazotates thought likely to be suitable on theoretical grounds as coupling agents in the alkaline phosphatase method. Cold formalin (4°) fixed (16-hr.) frozen sections (15 μ thick) of rat kidney were used, in veronal acetate buffer at *p*H 9·2. A note was made of (1) the speed of the reaction, (2) the rate of decomposition of the diazonium salt, (3) the colour of the final product, and (4) the type of precipitate. The results, in the case of nine stable diazotates, appear in the accompanying table.

Diazonium salt of	Inhibition	Decomposition	Colour	Diffuse or particulate
1. 1-Amino-anthraquinone	+++	+++	Brick-red	Diffuse
2. 4-Benzoylamino-2 : 5 dimethoxy-aniline	+	+	Black	Particulate
3. *p*-Nitroaniline	+++	++	Brick-red	Particulate
4. 4-Chloro-2-nitro-aniline	++++	+	Rose-red	Particulate
5. 2 : 5 Dichlor-aniline	++	++	Red-brown	Particulate
6. *o*-Dianisidine	+	++++	Black	Diffuse
7. 4-Chloro-*o*-anisidine	+	++	Brick-red	Particulate
8. 5-Nitro-*o*-anisidine	++	+++	Red-brown	Diffuse
9. 5-Chloro-*o*-toluidine	+	nil to +	Brown	Particulate

*p*H 9·2

Degrees of inhibition are registered from + to ++++, the former indicating almost complete absence. Similarly, in the case of decomposition, one + means practically no visible staining of the background structures. The reference 'particulate' means that the dye particles were large enough to be clearly visible with the 2/3 objective; diffuse means a particle size not appreciable at this magnification.

The question of diffusion of the reaction product was controlled by incubating two sections face to face, one inactivated by heat (15 min./90°) and Lugol's iodine solution (15 min.), the other untreated. No diffusion of the reaction product was detected with any of the salts within the limits (100 μ) of the distance between the two sections, provided that the concentration of the diazonium salt was sufficiently high. The optimum concentration for all these salts was found to be in the region of 1 mgm. per ml. substrate solution. With stronger concentrations, in the region of 5 mgm. per ml., inhibition was excessive, and with lower concentrations (0·1–0·2 mgm./ml.) two effects were noted. First, diffusion of α-naphthol occurred which was greater than 100 μ, and secondly, the final azo dye product was not as deeply coloured. With those salts producing a black dye, for example, the resulting dye was invariably red. Absence of enzyme inhibition by salts 2, 6, 7 and 9 was indicated by the production of a strongly positive result in 2–5 min., using the optimum concentration of diazonium salt in each case. With all the other salts inhibition was considerable. The decomposition of salts 2 and 9 was negligible, even after incubation for 2–4 hr., and with salt 7 it was only slight up to 1 hr. Salt 6, on the other hand, rapidly stained the tissues dark brown. Size of precipitate was largest with 2, smaller with 7 and very much smaller with 6; but in spite of this the reaction with salt 9 (diazotate of 5-chloro-o-toluidine) is the best so far obtained in respect of speed, colour and lack of decomposition.

With a suitable diazonium salt, the coupling azo dye method, applied to formalin-fixed frozen sections, should become the method of choice for the investigation of alkaline phosphatase in normal and pathological tissues.

Separation of the 2,4-Dinitrophenylhydrazones of Volatile Aldehydes and Ketones by Paper Chromatography

It is possible to separate the dinitrophenylhydrazones of keto-acids by paper partition chromatography with the usual two-phase alcohol – water solvents[1,2]. Aldehydes and ketones without a carboxyl group are not appreciably separated by this means because, being less soluble in aqueous media, they have uniformly high R_F values. Rice, Keller and Kirchner[3] were able to separate a number of these compounds by using single-phase solvents such as diethyl ether – petroleum ether. They also found that filter paper impregnated with silicic acid was helpful. Kostir and Slavik[4] used paper on which the solvent phases were reversed. They acetylated strips of filter paper and used two-phase solvents such as ethanol-chlorobenzene, the ethanol phase being the mobile one. In this way they separated acetaldehyde, formaldehyde, acetone and a number of keto-acids and dicarbonyl compounds.

The following method gives improved separations of the dinitrophenylhydrazones of a number of aldehydes and ketones and has been useful in the detection of volatile aldehydes and ketones dissolved in petroleum ether in quantities greater than 10^{-7} gm. mole. The non-aqueous two-phase solvent methanol – heptane is used, the heptane phase being the mobile one. The slight modifications that are necessary to obtain equilibrium conditions in the chromatographic chamber with these volatile liquids have been described[5]. By the method of descending irrigation, the solvent front moves about 20 cm. in an hour. The yellow spots, which are somewhat elongated, can be revealed more clearly by spraying with aqueous 10 per cent sodium hydroxide solution. The red-brown colour obtained varies slightly with the compound and is sometimes an aid to identification.

The accompanying table shows the R_F values (± 0·02) obtained for the dinitrophenylhydrazones of the compounds from a run of about 20 cm. at 20° C. on Whatman No. 1 filter paper.

Formaldehyde	0·09	Acetone	0·30
Acetaldehyde	0·18	Methyl ethyl ketone	0·43
Propionaldehyde	0·32	Methyl *n*-propyl ketone	0·53
n-Butyraldehyde	0·42	Methyl *n*-butyl ketone	0·65
n-Valeraldehyde	0·54	Furfural	0·06
n-Caproaldehyde	0·57	Acrolein	0·21
		Crotonaldehyde	0·22

Keto-acids and dicarbonyl compounds do not travel.

If the values for the homologous series of derivatives of saturated aldehydes are used for calculating the corresponding R_M values[6], and these plotted against the number of methylene groups in the aldehyde, the points lie approximately on a straight line. For the ketones a similar graph is obtained.

The work described in this paper was carried out as part of the programme of the Food Investigation Organization of the Department of Scientific and Industrial Research.

Proline and Hydroxyproline in Leaves

In the course of investigations on the nitrogen metabolism of plants, the distribution of free amino-acids in the leaves of a number of plant species was studied by the circular paper chromatographic technique[1]. The occurrence of proline and hydroxyproline in relatively high concentrations in some of the leaves investigated prompted us to report these preliminary observations.

Fresh leaves were extracted with ethyl alcohol by blending 20-gm. portions with 80 ml. of alcohol (final concentration, 75 per cent) in a Waring blendor for about 5 min. After centrifuging, the alcohol extract was well shaken with three times its volume of chloroform and again centrifuged. The aqueous layer containing the free amino-acids was used for chromatography. The method followed for running the chromatograms was essentially the same as that described by Giri and Rao[2] using Whatman No. 1 filter paper and *N*-butanol–acetic acid–water as the developing solvent.

Among the plants investigated, those belonging to the genus *Citrus* (*Citrus decumana*, *Citrus acida*, *Citrus medica* and *Citrus aurantium*) and family Rutaceæ contained high concentrations of free proline in their leaves, compared to other amino-acids present. Although proline is distributed widely in plant tissues, the occurrence of free hydroxyproline in high concentrations has not been reported so far. However, Joslyn and Stepka[3] found traces of free hydroxyproline in prune extract. Dent *et al.*[4] could not detect this amino-acid in potato tubers although twenty-one other amino-acids were identified. However, the circular paper chromatograms of fresh sandal leaf extracts (*Santalum album*) showed the presence of hydroxyproline, proline, arginine, glutamic acid, alanine and traces of other unidentified amino-acids. The dried sandal leaf extract contained, in addition, leucine (or *iso*leucine), phenyl alanine, valine and tryptophane. But the most prominent and intensely coloured (yellow) band was that of hydroxyproline. Proline and hydroxyproline were identified by their position and the characteristic yellow colour of their bands on the chromatogram, and further confirmed by the specific test with isatin[5].

Sandal leaves collected in the morning and dried at 50° C. and powdered showed there was no deterioration in the hydroxyproline content after drying. 50 mgm. of powder were extracted four times with 5-ml. aliquots of 75 per cent alcohol. The combined extract was treated with chloroform as before and the aqueous layer used for the estimation of hydroxyproline by the method of Neuman and Logan[6] involving oxidation with alkaline hydrogen peroxide and copper sulphate, followed by acidification and reaction with *p*-dimethyl amino-benzaldehyde. The dried healthy leaves contained about 1·7 gm., and a sample of spiked leaves contained 3·0 gm., of hydroxyproline in 100 gm. of material. The predominance of hydroxyproline over other amino-acids present in the leaves of *Santalum album* is striking. So far as we are aware, this is the first record of the occurrence of free hydroxyproline in high concentrations in leaves.

The practical application of these results in the preparation of proline and hydroxyproline from leaves at least on a laboratory scale is an inviting possibility. Investigations in this regard and on the role of the two amino-acids, especially of hydroxyproline in the nitrogen metabolism of spiked and healthy sandalwood trees, are in progress. This has added significance in view of the recent finding of Steinberg[7] that hydroxyproline was toxic to tobacco seedlings, even at 5 p.p.m., indicating a specificity of action.

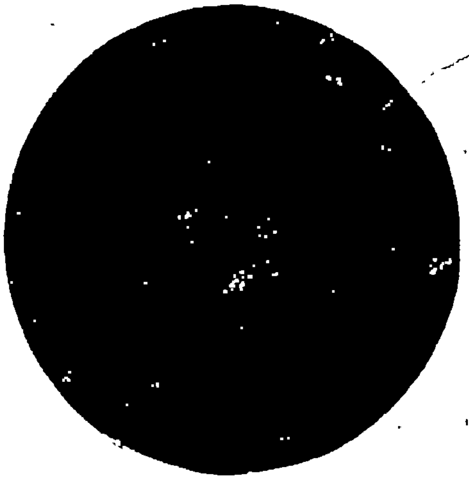
Improvements in Optical Fourier Synthesis

A METHOD has recently been described of producing Fourier syntheses of centro-symmetrical projections by means of optical interference[1]. The biaxial nature of mica was used to introduce into the diffracting beams both intensity and phase relations corresponding to those of the X-ray spectra. The resolution obtained was poor, and it was suggested that this could be improved by using lenses corrected for spherical aberration.

Corrected doublets have now been fitted to the existing apparatus, and considerably better resolution has been obtained. The accompanying photograph is of the optical Fourier synthesis of hexamethylbenzene, based on the X-ray data of Brockway and Robertson[2]. This is a striking improvement over previous work.



Optical Fourier synthesis of hexamethylbenzene

In a recent article[3] it was suggested that, unless the available beam of parallel light were greatly extended, this method of optical Fourier synthesis would probably be of very limited application. Work now in progress will make it possible to pack more terms into the available beam; it is hoped that in this way it will be possible to accommodate a maximum index of 15 in each direction. This should greatly increase the scope and usefulness of the method.

A full account of recent developments will be published elsewhere.

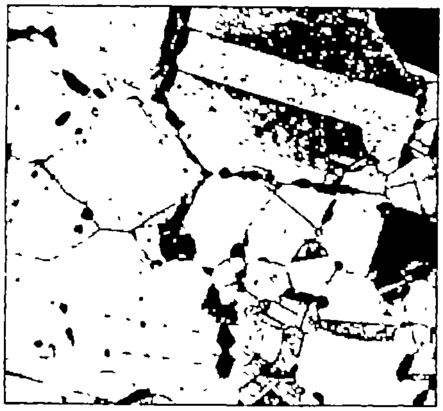
Lattice Vacancies and Porosity in Copper–Nickel Alloys

IN work on the aluminium–zinc[1] and gold–nickel alloy systems[2], it has been shown that lattice vacancies occur in solid solutions when Brillouin zones are filled. Similar experiments have been made on copper–nickel alloys, and it is found that lattice vacancies occur in these alloys particularly when they contain less than 80 per cent nickel, the maximum being about 2 per cent at 45 per cent nickel.

The alloys were melted and solidified *in vacuo*, annealed in a vacuum for seven days at 900° C., reduced in thickness by 50 per cent by hammering at room temperature and then annealed *in vacuo* at temperatures between 700° and 970° C. for periods of up to 4,175 hr. Density measurements were made from time to time. It has been found that the alloys grow progressively, the amount of growth depending on the temperature of annealing and number of lattice vacancies.

The accompanying photograph shows the micro structure of an alloy containing 80 per cent copper after annealing for 4,175 hr. at 900° C., during which treatment its volume increased by about 4·5 per cent. It will be seen that considerable micro porosity has developed during treatment. Almost all the porosity occurs in crystal boundaries with very little at twin boundaries or in the crystals.



Micro porosity developed in 80/20 copper–nickel alloy by prolonged annealing *in vacuo*. × 150

Alloys containing less than 20 per cent copper, in which there are comparatively few vacancies, show less than 0·1 per cent growth under similar conditions.

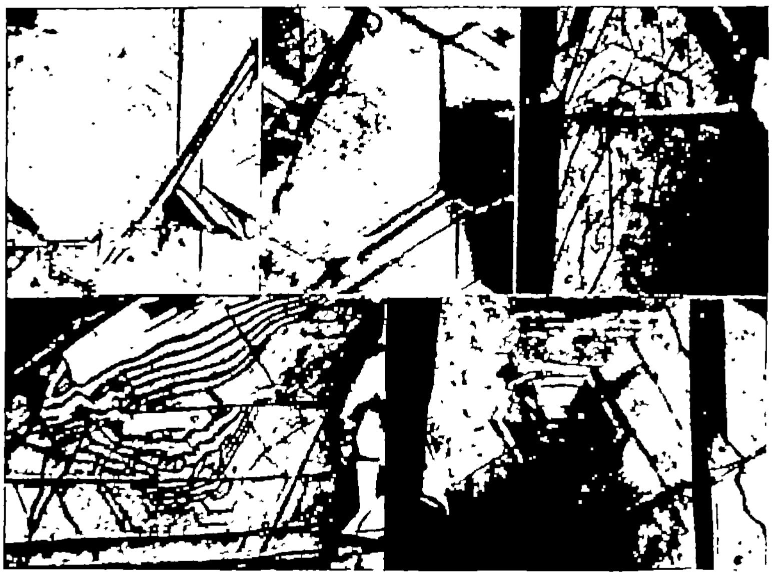
Spiral Growth on Graphite

SPIRAL growth patterns have been observed on natural graphite. Typical spirals are shown in the accompanying photographs. The spirals have been predominantly hexagonal, although some with curved edges, particularly at the centre of the spiral, have been noted. The step-heights vary widely; the step-height of the spiral shown in (*b*) is about 500 A., those in (*c*) and (*e*) are apparently many orders larger. Photograph (*d*) shows a double spiral and serves at the same time to give an idea of the density of spiral patterns. Areas have been noted in which the density of spirals is of the order of 10^4 per cm.^{2}.



Spiral growth on natural graphite: (*a*) 1,000 ×. (*b*) 1,500 ×. (*c*) 150 ×. (*d*) 500 ×. (*e*) 150 ×

Of the graphites studied, those which lend themselves best to the observation of spirals have been obtained from the crystallized limestones of the Grenville series ranging from the Adirondacks to north of Quebec. The spiral patterns are observed on the natural surfaces of the embedded graphite and also on surfaces exposed by carefully separating the graphite layers. No spirals have been observed on the surface of the limestone at the point from which the graphite is removed. Spirals have not been observed on samples of graphite obtained from Ceylon, nor from columnar graphite from Quebec. Neither of these samples has the distinct sheet-like structure of the Grenville series graphite. It is not possible yet to determine whether it is simply more difficult to resolve the spirals or whether they are not present on such samples.

The observation of growth spirals on graphite may be taken as evidence—in the same sense at least as has been established for silicon carbide[1] in particular —that graphite may grow from screw dislocations. It is believed that certain structural problems in graphite may be clarified knowing that screw dislocations may be present. Thus, the polytypism in graphite may be developed along lines similar to those applied to the problem in silicon carbide[2].

As developed *a priori*, the theory of crystal growth by screw dislocations is considered to pertain to growth under somewhat restricted conditions[3]. If spiral growth on graphite is limited to graphites from certain localities, the observation of spiral growth may be of assistance in interpreting the geological origin of graphites.

Relativity and Indeterminacy

Without wishing in any way to disagree with H. Bondi's view[1] that "relativity demands a non-deterministic theory", I would suggest that his final summing-up is somewhat misleading. He says: "The flow of time has no significance in the logically fixed pattern of events demanded by deterministic theory, time being a mere co-ordinate. In a theory of indeterminacy, however, the passage of time transforms statistical expectations into real events".

In the case of deterministic theories, we must surely distinguish between reversible and irreversible determined processes. Time, in statistical but determined laws, as distinct from dynamical laws, surely has a very definite significance, for example, in its relation to entropy changes and especially to those processes which Prof. A. R. Ubbelohde[2] has described as "disentropic". (These are defined as "happenings which turn against the trend towards increasing entropy".) Many statistical laws depend on determined processes. The motions of individual components may be difficult to observe, or too numerous or complex to calculate, yet their behaviour certainly falls outside the range of appreciable indeterminacy.

It is true, if not a truism, that where there is no cause–effect relation, real events become actual from mere statistical expectations during the course of time. But can this passage of time rightly be described as the transforming agent? This would involve a return to causality with time as the cause!

I would suggest that there is at least as much difference between time used as a co-ordinate in dynamical processes and time describing local variations in efficiency (both being determined) as there is between either of these and time during which (not by which) non-determined statistical probabilities become actualities.

[1] Bondi, H., *Nature*, 169, 660 (1952).

[2] Ubbelohde, A. R., "Time and Thermodynamics", 97 (Oxf. Univ. Press, 1947).

In a recent communication in *Nature*[1], Mr. H. Bondi (in common with a large number of writers in the field) took as a fundamental postulate of relativity the principle P that effects are delayed relative to causes by amounts corresponding to transmission speeds less than or equal to the velocity of light, c. This led him to the conclusion that indeterminacy is fundamental to relativity, and so we must abandon the complete determinacy contemplated in classical physics (and, it should be noted, in at least one approach to quantum theory[2]). The argument was, more or less, that there is no unique cause–effect link, and so no unique meaning for P, in a deterministic system.

The principle P is commonly employed in setting up a system of space–time co-ordinates by means of light signals, and it appears that this is the use envisaged by Mr. Bondi. However, the important fact in such a co-ordinate formation is not that c is the maximum speed between cause and effect, but rather that c is a speed on which relatively moving observers will agree for all directions of motion.

One can set up one's own co-ordinate system in any number of ways, using light signals or not; all that is needed is a unique (to an arbitrary factor and self-consistent method of correlating event which occur at separated spatial and tempora positions. Whether or not these events are relate through a cause–effect link is irrelevant and, som would say, meaningless.

If two correlated events occur at separations Δ and Δt, then one can introduce an effective speed o correlation, $s = |\Delta r/\Delta t|$. This need not be th speed of a ponderable body nor of a light signal it could just as well be, for example, a group spee or the speed of the juncture point of two straigh edges in relative motion. It need not, then, be confined to values less than or equal to c. In this connexion, it may be pointed out that no escape, fo example by considering discontinuous fields, nee be made from the fact that group speeds ca exceed c.

A difficulty arises only if we attempt to compar our measurements with those made, on the sam events, in a relatively-moving co-ordinate system. I general, correlation is obtained by means of Lorentz rather than Galilean, transformations, and in particular, the effective speeds are found equal (for al directions) in those cases when $s = c$ rather tha when s is infinite. It is these circumstances that giv c its unique position in the establishment of co-ordinate systems. Cause–effect links and limitin velocities are not involved, and conclusions base on them are therefore irrelevant to the fundamental of relativity.

For those who may not agree with the foregoing I shall add the following remarks. There are alternative, though less popular, methods of introducin relativity which postulate neither a cause–effect lin nor limiting velocities. We are quite at liberty t adopt one of these other methods, and many woul choose to do so. Mr. Bondi's apparent preference fo P does not commit the rest of us to indeterminacy any more than Prof. P. A. M. Dirac's interpretation of his symbolism—whether it leads to quantizatio or not—commits us to an æther.

It is not clear why the subject of statistics shoul throw any light on this problem, as Dr. G. W. Scot Blair suggests. There are two possible logical foundations for the use of statistics in physics: either, i the framework of a fully deterministic theory, wherei statistics may be used for the discussion of problem of such complexity that the detailed application o the supposedly known physical laws is impracticable or within a non-deterministic theory, where the mo basic physical laws may be concerned with the stat ment of probabilities.

In the former case, time is a co-ordinate, that, lik space, is required for plotting the world lines of th particles. Whether this fixed pattern of world line is simple so that we can construct it directly fro the deterministic laws, or whether it is so complicate that we use statistical theorems as well as th deterministic laws in the calculation, does not alte the significance we attach to the various co-ordinate

In the case of indeterminacy, the passage of tim has a further significance, being concerned with th realization of probabilities. A variety of verbal methods of description can be used for this, from which Dr. Scott Blair has chosen some.

In the unique pattern of world lines appropriate to a completely deterministic world, it is not clear how an analysis would reveal the rules of causality (the physical laws). Since every set of events would be in some way unique, any selection of apparently recurring patterns would be arbitrary.

Such sets of recurring patterns would be the only way of investigating possible causal relations. It would, however, still require an arbitrary judgment to say which patterns represent direct cause–effect relations and which represent the various effects of some previous cause. In a deterministic world, it would be necessary to understand all causal connexions in the entire pattern before any particular laws of causality could be singled out.

In a non-deterministic system the situation is quite different. If it is found that certain events occur invariably after the occurrence of some uncaused event, but not in its absence, then a causal connexion can immediately be inferred, for no such events can be regarded as distant effects of earlier causes.

Mr. C. O. Hines presents a completely acceptable definition of the velocity c from the experimental verification of the Lorentz transformation. But he does not point out that this implies a limiting velocity c also for the transfer of information if cause–effect relations are to be unidirectional in time. We are therefore led back to what Mr. Hines calls principle P, and so to the starting point of this discussion.

The essential fact is that no *step-by-step* investigation of Nature is logically possible without some indeterminacy. This statement does not conflict with the possibility of constructing deterministic mathematical theories to cover any known field, but denies their scientific utility.

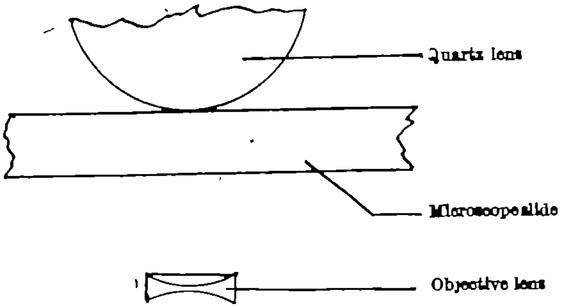
Measurement of Thicknesses of Fine Particles

A method for measuring thicknesses of particles in the sub-sieve range has been devised. Measurements are made using the Vickers projection microscope. The apparatus required is an attachment to the sub-stage condenser which replaces its front lens; it consists mainly of a quartz spherical lens, which is allowed to make contact with a microscope slide carrying a dispersion of fine particles mounted dry on its uppermost surface—which is most distant from the objective lens—as shown in the diagram.

Contact is made on a strip which has been wiped free of particles, near the left-hand edge of the slide. The point of contact is focused on to the screen and is arranged to lie at the middle of the left-hand side of the screen. When the slide is traversed from right to left, particles enter the field and are seen to meet the lens at varying distances from the point of contact of lens and slide. These distances are proportional to the square roots of the thicknesses of the particles.



By having interchangeable spherical lenses of different diameters and the choice of suitable magnifications, lens diameter being decreased when the magnification is increased, the thicknesses of particles of diameters in the range 76–3 microns can be measured with the same degree of accuracy throughout, the standard error of a single measurement being 5 per cent, if the smallest thickness measured is not less than 0·4 micron.

Transmitted light is used for all measurements, and the illumination and image definition do not deteriorate even when objectives of 4 mm. and 2 mm. focal lengths are used. When these particular objectives are used, rectangular No. 1 microscope cover slips carry the particles.

This method of measurement is eminently suitable for the Vickers projection microscope but is not easily adapted to the normal light microscope; it could be readily adapted to the inverted microscope, measurements being made with a suitable eyepiece graticule.

The method is the subject of a patent application and more details will be reported at a later date.

Scintillation Spectrometer Studies on the Decay Schemes of Silver-110, Antimony-124 and Iodine-131

In order to study the decay schemes of radioisotopes, we have used two scintillation spectrometers in coincidence. The construction of the spectrometers used and the measuring technique have been described earlier[1]. The pulses from one of the spectrometers are analysed by a single-channel pulse analyser. Pulses corresponding to a certain energy-range are selected by the channel, and the output pulses from the analyser are fed to the sweep-trigger of an oscilloscope. The pulses from the second spectrometer are led to the vertical deflexion plates of the oscilloscope. Only pulses which are in coincidence with those selected by the pulse analyser then appear on the screen. The coincidence-rate is 10–100 pulses per minute. The screen is photographed for a few hours. A picture of the pulse-height distribution is then obtained on the photographic plate; the density at a particular point is a measure of the number of pulses with the corresponding height. The density is determined by means of a microphotometer, and, from the known density curve of the plate, one obtains the pulse-height distribution curve. With the pulse analyser one thus selects pulses corresponding to a certain beta- or gamma-ray energy, and from the shape of the coincidence spectrum obtained one can infer what gamma-rays are in coincidence with the selected radiation.

The apparatus described here has been used to investigate some decay schemes. The following results have been obtained:

Silver-110. It has been possible to determine in a satisfactory way the coincidence relations of the two beta-components and of the strongest six gamma-rays. Our results are in complete agreement with the decay scheme proposed by Siegbahn[2].

Antimony-124. Our results agree on the whole with the decay scheme suggested by Kern *et al.*[3]. We have found, however, that the 2·06-MeV. gamma-ray probably does not go to the ground-state but to the first excited level at 0·60 MeV.

Iodine-131. From our measurements, we conclude that the only coincident gamma-rays are those at 80 keV. and 284 keV. The gamma-rays at 638 keV. and 720 keV. go directly to the ground-state. The results obtained thus support the decay scheme suggested by Metzger and Deutsch[4]. The coincidence measurements described here do not agree with the gamma–gamma coincidence experiments performed by Bell *et al.*[5]. On the other hand, they agree with the beta–gamma coincidence measurements published quite recently by Ketelle *et al.*[6].

A detailed account of this work will appear in *Arkiv för Fysik*.

Use of Radioactive Tracer in the Study of Insect Populations (Lepidoptera)

It has up to now been impossible to mark larvæ in the wild because of their frequent skin changes and their pupation; consequently, the method usually adopted in population studies of distinguishing an insect with a spot of cellulose paint is not applicable to them. It was therefore decided to attempt the marking of larvæ by feeding them on radioactive material.

A suitable isotope would require the following properties: a half-life long enough to survive the pupal period yet short enough to ensure against building up radioactive populations in the wild; easy ingestion and incorporation into the food plants and afterwards into the living tissue of the insect; slow elimination. Sulphur-35 answers these requirements, having a half-life of 87·1 days and being an essential element in both plant and insect physiology. However, it has the drawback of emitting a low-energy beta ray (0·168 MeV.). This difficulty was overcome by the use of a Geiger–Müller counting tube fitted with a thin mica window.

The species chosen for study were *Panaxia dominul* and *Arctia caja*. The food-plants selected for ther were dead nettle (*Lamium* spp.) and dock (*Rume* spp.), respectively, and these were treated wit sulphur-35. The following procedure was adopted t ensure its uniform incorporation throughout the plant proteins. Plants stripped of most of their olde foliage were established in water culture for two t three days, during which time root regeneratio occurred. They were then supplied with one par in a million of sulphur (given in the form of potassiu sulphate) and 100 micro-Curies of sulphur-35 per litre A balanced medium containing necessary material other than sulphur was then added at weekly interval and, after three weeks or more, the larvæ were fe on these. It was found that if the plants wer used shortly after treatment with sulphur-35, th bulk of this was concentrated in the young tissues so that the degree of radioactivity varied greatl from leaf to leaf, with the result that no uniformit of count was shown by the larvæ which had fed on them.

Nearly full-fed larvæ of *P. dominula* fed on suc treated material for 65 hr. were presented to a mica-window counter tube in a lead castle and the count for one minute recorded. These gave only low counts, while their excreta were highly radioactive. When returned to non-radioactive food plants, however, they continued to show increasing counts for some hours, the reason being, no doubt, that the soft-ray sulphur was in the process of absorption and had not yet been incorporated into the superficial structures. Larvæ near to pupation ate less and therefore gave low counts. An arbitrary figure was taken of about 20 counts per minute above the background and larvæ were placed in one of two groups—those which 'qualified' over this value, and those which did not. In due course, they pupated and the pupæ showed counts comparable with their larval stage.

Six to eight weeks after radioactive treatment, the imagines hatched and it was noted that they all gave counts far in excess of those obtained from the larvæ and pupæ, so that all the 'qualifiers' showed counts two to six times higher and many of the 'non-qualifiers' were easily recognizable (experiment *C/A*, No. *A* 17, pupa 13 counts per min.; imago 79). This, doubtless, is due to the fact that an imago has a much greater surface area than a larva, in the more bulky body of which the majority of the beta-rays must be absorbed. Furthermore, it has been shown that there is a concentration of sulphur in the wings of some Lepidoptera[1].

It should also be pointed out that holometabolous insects are, in general, an excellent medium for such work, inasmuch that there can be no 'sulphur exchange' during the pupal stage and thereafter; the only loss occurs in the excretion of a small amount of meconium on emergence, while the chitinous pupal case does not appear to contain much sulphur. Further experiments using *Arctia caja* confirmed these results. Other relevant points which arose during these experiments were: a batch of ova laid by a female *A. caja* with a count of 417 per min. gave 676 counts per min. Dead and dehydrated larvæ and pupæ gave higher counts than when living, as probably less absorption in the body takes place, a fact of use in substantiating doubtful instances of radioactivity. There was no evidence of decreased viability among the treated specimens compared with their controls.

It is hoped in the near future to release a known number of radioactive larvæ into a normal population. By recapturing the individuals as moths, by such neans as mercury vapour lamps and assembling raps, and at the same time estimating the total of he imagines by the methods used by Fisher and Ford[2], t should then be possible to estimate for the first time the mortality-rate in the early stages :

$$\text{Total larval population} = \frac{\text{radioactive larvæ released} \times \text{total imagines caught}}{\text{radioactive imagines caught}},$$

Mortality = total larval population — total population of imagines.

Similar methods might be applicable in modified vays to ascertain total populations, larval deathates, dispersal activity, and other aspects of population dynamics as well as pigment chemistry in many orders of insects.

I wish to thank Dr. D. F. Shaw, of the Clarendon Laboratory, Oxford, for his advice on suitable sotopes ; also Dr. Scott Russell and Dr. R. P. Martin, f the Department of Agriculture, Oxford, and their ssistants, who both prepared the radioactive food lants and offered me their amenities and equipment. am grateful to Prof. G. E. Blackman for his enouragement and Dr. E. B. Ford for helpful sugestions. I am indebted to the Nuffield Foundation or a grant which made this work possible.

A New Linkage in the House Mouse : Vestigial and Rex

IN 1947, Wright[1] (Mrs. M. E. Wallace) reported e remarkable discovery of recombination frequencies xceeding 50 per cent in linkage group VII of the ouse mouse. Such a phenomenon had been predicted a theoretical possibility by Jennings[2] in 1923 for stantially the right reasons, although he based his gument on a theory of two-strand crossing-over and simplified discontinuous theory of interference. Mrs. Vallace found that the genetic markers sh_2 (shaker-2) nd wv_2 (waved-2), which show loose linkage with ach other of about 30 per cent recombination frequency, both recombined with sex with a frequency f about 56 per cent. This finding was the first case f partial sex-linkage to be reported in any mammal ther than man. Rex (symbol *Re*), which was known be about 20 per cent from sh_2 and about 40 per nt from wv_2, assorted independently of sex in other ata from the same department.

A theory of interference between adjacent chiasata advanced by Fisher, Lyon and Owen[3] offered basis for the resolution of these apparent contraictions. From this theory it is calculated that the equency of recombination with an end marker rises, the map distance increases, to a maximum of bout 56 per cent before falling back to the 50 per nt level. They accordingly prepared a map of the x-chromosome as follows :

while specifically not excluding the possible order sex wv_2 sh_2 *Re*.

Dr. T. C. Carter[4] has very kindly sent me additional data on recombination between sex and *Re* collected since the above maps were proposed. His results, when combined with those of Fisher, Lyon and Owen, give 52·2 ± 1·1 per cent as an estimate of the recombination frequency, and suggest that the distance from sex to *Re* in the above map is a slight underestimate, and that the second alternative map should be given distances roughly as follows :

The purpose of this communication is to present evidence that : (i) the recessive mutant 'vestigial' (symbol *vt*), found and described by Heston[5], is linked with *Re*, and lies at a distance from it of about 19 centimorgans on the same side as sh_2 ; and (ii) females heterozygous for the two markers produce a much higher proportion of recombinant gametes than do males.

512 mice were raised from backcrosses of double heterozygotes of both sexes, in both the coupling and the repulsion phase. The results are summarized in the accompanying table.

Segregating parent	Phenotypes of progeny				Total	Recombination frequencies (per cent)
	+ *Re*	+ +	*vt Re*	*vt* +		
♂ $\frac{+\ Re}{vt\ +}$	80	9	19	59	167	17 99 ± 2·20
♂ $\frac{+\ +}{vt\ Re}$	11	57	56	16	140	
♀ $\frac{+\ Re}{vt\ +}$	29	15	15	33	92	27 55 ± 3 15
♀ $\frac{+\ +}{vt\ Re}$	13	39	48	13	113	

In order to allow for viability differences, the recombination frequencies for the two sexes are estimated from the combined coupling and repulsion data by the method of Fisher[6]. As shown in the table, the estimated recombination frequency for males, p_m, is 17·99 per cent, and its standard error, s_m, is 2·20 per cent. The estimate for females, p_f, is 27·55 per cent and its standard error, s_f, is 3·15 per cent. The corresponding estimates, p_c and s_c, for the sexes combined are 21·66 per cent and 1·82 per cent respectively. The significance of the sex difference is given by :

$$\chi^2_{(1)} = \frac{(p_f - p_c)(p_c - p_m)}{s_c^2} = 6{\cdot}52 \qquad P < 0{\cdot}02.$$

The more direct test afforded by a 2 × 2 contingency table runs the risk of a slight bias if both segregating genes affect viability.

In order to determine the position of *vt* relative to other marked loci in the same chromosome, tests were made of the joint segregation of *vt* with sh_2. The resulting estimate of recombination was 1·7 per cent, with 9·5 per cent as the upper fiducial limit at the 2½ per cent probability level. Hence *vt* lies within a few units of sh_2.

It should, therefore, according to either of the alternative maps given above, show more than 55 per cent recombination with sex. Extensive tests were made of the joint segregation of *vt* and sex. These gave an estimated recombination frequency of 51·64 ± 1·94 per cent, which accords poorly with expectation. This result, if combined with other data to which reference has been made, can only be accommodated by a map approximately as follows (map distances based on male gametogenesis) :

$$sex \overset{95}{\text{―――――――}} wa_1 \overset{35}{\text{―――――――}} (vt, sh_2) \overset{20}{\text{―――――}} Re$$

On the other hand, the position on the sex chromosome of the centromere, as described cytologically by Slizynski[7], militates against such an interpretation. I have discussed the problem with Sir Ronald Fisher and Mrs. Wallace; they have suggested to me that the true explanation of Mrs. Wallace's observations may lie not in partial sex-linkage but in 'affinity', a new genetic phenomenon which other work has led me to postulate, and on which both Mrs. Wallace and I hope shortly to publish preliminary evidence.

My thanks are due to Prof. L. C. Dunn for the gift of vestigial mice; to Dr. T. C. Carter and Dr. D. S. Falconer for the gift of Rex and shaker-2 mice; and to Dr. E. B. Ford and Sir Ronald Fisher for advice and encouragement. This work was done while I was in receipt of a research training grant from the Medical Research Council. I also wish to thank the Agricultural Research Council for the provision of facilities.

Body-Temperature of Arthropods

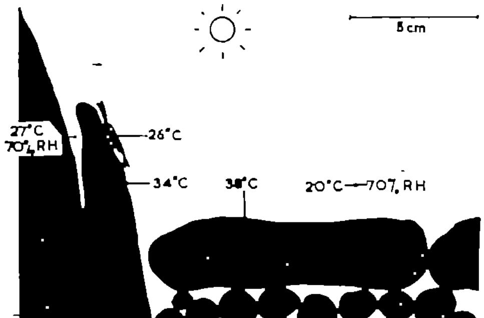
PARRY[1] has recently concluded that evaporation is insignificant as compared with radiation and convection in determining the equilibrium temperature of small animals in direct sunlight, except in unusual circumstances. While this is probably true for insects and spiders, in which evaporation of water is severely restricted at low temperatures, isopods and millipedes are known to evaporate water more rapidly, and I am prompted to report the following preliminary field observations on the body-temperature of *Ligia oceanica*.

Three of these animals were exposed to direct sunlight on the surface of a concrete quay at Dale Fort (Pembroke) at 2.0 p.m. G.M.T. in August 1951. One was alive, another was freshly killed by chloroform and a third was also dead and thoroughly dry. A fine thermocouple was inserted into the rectum of each, and another thermocouple was in contact with the surface of the quay. During a 30-min. observation period, the quay surface temperature varied between 34° and 36° C., while that of the living and freshly killed *Ligia* dropped to 28° C. That of the dry specimen rose during the first 10 min. to within 0·5° C. of the temperature of the quay surface and remained there. The air, of relative humidity 66–68 per cent, was moving gently (force 1 on the Beaufort scale), and its temperature 2·0 cm. above the quay was 21° C. These results suggest that evaporation was playing a large part in determining the equilibrium temperature; but on theoretical grounds this will only be so if the evaporation factor in the heat balance-sheet (radiation + conduction = convection + evaporation) is of the same order of magnitude as the other factors. (Metabolism as a source of heat may be neglected.)

As regards radiation, Parry has shown that the mean total radiation load (long and short wave) upon a rectangular plate or bar exposed to the sun, with a surface reflectivity of 50 per cent, varies from 9 to 22 mW./cm.², according to its orientation. The radiation load of *Ligia* may therefore be approximately estimated at 15 mW./cm.². Conduction is an unknown value. The convection coefficient for a disc 1 in. × 3/32 in. at a wind speed of 50 cm./sec. ha been shown (also by Parry) to be 1·4 mW./cm.²/° C. and this amounts to 9·8 mW./cm.² for a temperature difference of 7° C. (*Ligia*, 28°; air, 21° C.). No measurement of the rate of evaporation was made during the field observations recorded above, bu laboratory measurements show[3] that in slowly moving air (c. 5·0 cm./sec.) having a saturation deficiency of 32 mm. mercury, *Ligia* at 30° C. loses water at the rate of 11·5 mgm./cm.²/hr. On the quay referred to above, the saturation deficiency (assuming the surface temperature of *Ligia* to be 28° C. and that of the surrounding air to be 21° C. at 67 per cent relative humidity) was 16 mm. mercury, so that evaporation would be approximately 16/32 × 11·5, or 5·75 mgm./cm.²/hr. Now at low wind speeds, the rate of evaporation from a free surface is approximately proportional to the square root of the ai velocity. This was 5·0 cm./sec. in the laboratory and has been taken as 50 cm./sec. (force 1 on the Beaufort scale) over the quay. At a conservative estimate, we may therefore double the rate of evaporation, giving 11·5 mgm./cm.²/hr., and this is equivalent to 7·7 mW./cm.².

The heat balance is now as follows (in mW./cm.²): 15 (radiation) + x (conduction) = 9·8 (convection) + 7·7 (evaporation). Without evaporation, the balance would be maintained largely by increasing the loss due to convection (to nearly 17·5 mW./cm.²), and this would mean raising the temperature of the animal to 33·5° C. (which is approaching the temperature found experimentally in the dry *Ligia*). It seems clear, therefore, that in this case evaporation is significantly affecting the equilibrium temperature

These considerations may help to explain the fact that *Ligia* and *Porcellio* were often to be seen on rocks in direct sunlight. The accompanying diagram shows the temperature and humidity measured at various points near the foot of an insolated red sandstone cliff, and it seems not unlikely that the high body temperature of *Ligia* below the shingle, where the air was still, and nearly (perhaps quite) saturated



Vertical section of base of cliff and shingle inhabited by *Ligia* (diagrammatic) ith water vapour, may result in a temporary up-ard migration to the cliff face, where evaporation nd convection together lower the body temperature.

The humidity measurements referred to were made ith a small electrical hygrometer, about the size f *Porcellio*. The instrument is to be described lsewhere shortly.

The observations recorded above were made while ı receipt of a grant from the Agricultural Research ouncil.

Pelagia in Manx Waters

The occurrence of the scyphomedusan *Pelagia* near lymouth referred to recently in *Nature*[1] reminds one hat early in October of 1899 the genus invaded Port rin Bay, Isle of Man, in astonishing numbers. It as a truly remarkable spectacle. The sea looked s if converted into a solid mass of the jelly-fish. he species had not been reported in Manx waters efore, nor has it been seen there since. They ppeared suddenly, remained for a short time, and s suddenly disappeared. When the record was osted to the late E. T. Browne, he was at first ery sceptical as to our identification ; but an examnation of some actual specimens enabled him to ecognize the animal as *Pelagia perla*. He assumed hat its presence in Manx waters was due to "a ortherly current bringing down animals through the orth channel from the Atlantic shores of Ireland nd Scotland". Two of the specimens are preserved n the Zoology Museum, University of Reading. It nay be added that on August 10, 1903, a large shoal f *Pelagia* appeared in Valencia Harbour, along with huge drift of Salpas on which the pelagias were eeding[2].

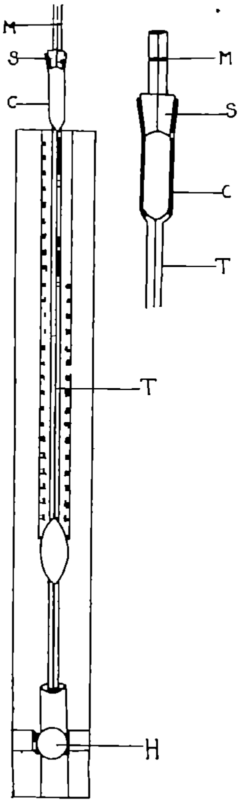
A Simple Device for measuring the Volume of an Aquatic Animal

DIFFERENT methods of determining the volume of mall animals have been described by Lowndes, Iolter, Kuenen and Smallman[1]. None of these is onvenient and simple for rapid measurements. I ave found the volumometer sketched here very seful. It consists of a long capillary tube T with a mall cylinder C closed with a stopper S to ensure a acuum seal. The capillary and the cylinder are lled with water and the cylinder is then closed with he stopper. By using the screw-head H at the ottom, mercury is forced from below and the water s raised up the capillary within the stopper to the nark M. Using a hand lens, the base of the water olumn in the capillary T is read to a fraction of a nillimetre. Water is lowered well below the stopper.



The creature whose volume has to be measured is dried with filter paper and dropped into the cylinder. When the stopper is replaced, the water is raised to the mark once more and the position of the base read. If the creature cannot be safely wiped with filter paper, the water in the cylinder is lowered until a short column of air enters the capillary and the animal is pipetted along with a minimum of water into the cylinder. The water around the creature is drained into the capillary, and a spill of filter paper is used to remove the last traces of water. The stopper is replaced and the column of water thus drained from the creature is measured. Next, the water is raised to the mark and its position read once more. The last reading minus the column of water drained from the animal will give the volume of the animal.

To test the accuracy of the apparatus, a copper wire, 0·315 gm. in weight and 35·1 c.mm. in volume, was cut into pieces ; the pieces were introduced into the apparatus with some adherent water and their votal volume was measured. The mean of ten readings was 34·928 c.mm.—an error of 0·57 per cent (S.D. ± 0·2207, S.E. ± 0·069). Volumes were measured on *Gammarus pulex*, using single specimens of different sizes, and the results were compared with volumes calculated from density measurements. The density was found by weighing groups of ten animals first in air and then in water ; from six such groups the average density at 20° C. was found to be 1·0665, varying from 1·032 to 1·087 (Lowndes gives the range as 1·065–1·086). To take an example, a specimen weighed 34 mgm. ; its volume calculated from density is 31·880 c.mm. The cross-sectional area of the capillary being 0·476 sq.mm., this volume corresponds to a scale-reading of 66·9 mm. When this specimen was introduced with some adherent water and drained into the apparatus, the mean of eleven readings was 70·3 mm., an error of 5 per cent (S.D. ± 0·511, S.E. ± 0·154) ; when the animal was dried before being introduced into the apparatus, the mean of ten readings was 63·9 mm., an error of 4 per cent (S.D. ± 0·679, S.E. ± 0·214).

I wish to thank Prof. J. Gray for permission to work in his Department, and I also wish to thank Mr. W. S. Darkin for assistance in the construction of the apparatus.

FORTHCOMING EVENTS

(*Meetings marked with an asterisk * are open to the public*)

Monday, October 6

Society of Engineers (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Mr. Hal Gutteridge: "Refuse-Sewage Composting—Engineering Aspects".

Society of Chemical Industry, London Section (joint meeting with the London and South-Eastern Counties Section of the Royal Institute of Chemistry, at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 6.30 p.m.—Dr. H. K. Cameron: "The Chemist in the Electrical Industry" (Chairman's Address).

Tuesday, October 7

Institution of Post Office Electrical Engineers (at the Institution of Electrical Engineers, Savoy Place, Victoria Embankment, London, W.C.2), at 5 p.m.—Mr. R. S. Phillips: "Engineering and the Postal Service" (Chairman's Address).

Chadwick Public Lecture (at the Royal Society of Tropical Medicine and Hygiene, Manson House, 26 Portland Place, London, W.1), at 5.30 p.m.—Dr. H. E. Magee: "Food as a Health Factor".*

Society of Chemical Industry, Agriculture Group (joint meeting with the Oils and Fats Group, at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Dr. F. B. Shorland: "New Zealand Researches on Animal Fats". (Members of the Food Group are invited.)

Wednesday, October 8

Institute of Petroleum (at Manson House, 26 Portland Place, London, W.1), at 5.30 p.m.—Mr. J. R. Joyce: "Methods of Atomizing Liquid Fuels".*

British Institution of Radio Engineers (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 6.30 p.m.—Annual General Meeting; Mr. W. E. Miller: Presidential Address.

Institution of Mechanical Engineers, Graduates' Section (at Storey's Gate, St. James's Park, London, S.W.1), at 6.30 p.m.—Mr. J. Halling: "Surface Finish Measurement".

Institute of Welding (at the Institution of Civil Engineers, Great George Street, London, S.W.1), at 6.30 p.m.—Mr. A. Robert Jenkins: Presidential Address.

Society of Chemical Industry, Corrosion Group (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 6.30 p.m.—Discussion on "Filiform Corrosion and related Phenomena".

Thursday, October 9

Linnean Society of London (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Dr. William J. L. Sladen: Colour Films and Slides of the Falkland Islands and Antarctic.

Institution of Electrical Engineers (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Colonel B. H. Leeson: Inaugural Address.

Friday, October 10

Royal Astronomical Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Scientific Papers.

Saturday, October 11

British Psychological Society (in the Department of Psychology, University College, Gower Street, London, W.C.1), at 2.30 p.m.—Mr. James Laver: "Fashion and the Freudians".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Assistant Lecturer or Lecturer in Geography—The Registrar, The University, Bristol 8 (October 10).

Physicist or Physical Chemist (with a good honours degree) to take charge of laboratory investigations of problems in coal preparation and treatment in which physical chemistry plays a major part (Ref. TT/534); a Scientist (with a good honours degree and an interest in physical chemistry or in the general properties of matter) (Ref. TT/535), and Scientific Technical Officers trained to degree standard (Ref. TT/536); in the Physics Department of the Central Research Establishment at Stoke Orchard, Cheltenham—The National Coal Board, Establishments (Personnel), Hobart House, Grosvenor Place, London, S.W.1, quoting the appropriate Ref. No. (October 11).

Physiologist (with a good honours degree in physiology, and research experience, preferably involving the perfusion of isolated organs) for research on the bovine udder—The Secretary, National Institute for Research in Dairying, Shinfield, Reading (October 11).

Principal Scientific Officers (Ref. 100) (with a first- or second-class honours degree in physics engineering or mathematics, or alternatively have high professional attainments together with suitable experience and responsibility, and for Position 1, extensive experience on radio receivers, including high-quality reception of radio communication, and experience in ionospheric reception; and for Position 2, extensive experience in circuit research and design particularly related to radar, electronic computors, or pulse communication systems) for the planning and supervision of the activities of a group undertaking research and development on all aspects of radio communications, a Senior Scientific Officer (Ref. 101) (with an honours degree in mathematics and physics and with some experience in the application of mathematical assessment to physical problems) as Mathematician in Telecommunication Group; a Scientific Officer (Grade 1) (Re 102) (with a degree, preferably with honours, in physics or electrica engineering, together with experience in ionospheric investigatio transmission and reception) to undertake, under supervision, researc and development work on all types of high-quality radio reception an Experimental Officer (Grade I) (Ref. 103) (with a degree i science and experience in radio communication) to undertake, unde supervision, the development of new defence equipment in the fields o radar and telecommunications, in the Commonwealth of Australi Supply Department, Electronics Research Laboratory, Salisbury—Senior Representative, Department of Supply, Canberra House, 8 Jermyn Street, London, S.W.1, quoting the appropriate Ref. N (October 13).

Station Chemists at Croydon A and B Stations, and Littlebroo Power Station—The Establishments Officer, British Electricit Authority, South Eastern Division, Lower Ham Road, Kingston-upo Thames (October 13).

Research Assistant in the Department of Pharmacolog and Therapeutics in the Medical School, Dundee—The Secretar The University, St. Andrews (October 15).

Electrical Engineers for service in the Admiralty—The Civ Service Commission, Scientific Branch, Trinidad House, Old Burlington Street, London, W.1, quoting S.210/52 (October 16).

Professor of Structural Engineering at the University of th Witwatersrand, Johannesburg—The Secretary, Association of Univer sities of the British Commonwealth, 5 Gordon Square, London, W.C. (October 25).

Analytical Chemist in the Government Analyst's Laborator Salisbury—The Secretary, Southern Rhodesia Government, 429 Strand London, W.C.2 (October 31).

Lecturer in the Department of Electrical Engineering University of Cape Town—The Secretary, Association of Universitie of the British Commonwealth, 5 Gordon Square, London, W.C. (Cape Town, October 31).

Smartt Memorial Scholarship for research in some subject o matter bearing upon agriculture, at the University of Cape Town o elsewhere in South Africa—The Secretary, Association of Universitie of the British Commonwealth, 5 Gordon Square, London, W.C.1 (Cap Town, October 31).

Agricultural Statistician (with a degree in mathematic statistics, as well as experience in the statistics of field experiments)—The Secretary, Tobacco Research Board, P.O. Box 1909, Salisbury Southern Rhodesia (December 1).

Agriculturist, Somaliland Protectorate, to take charge of experi mental scheme for date cultivation with a view to its eventual ex pansion—The Director of Recruitment (Colonial Service), Colonia Office, Sanctuary Buildings, Great Smith Street, London, S.W.1 quoting Ref. CSC.63/5/01.

Assistant Mechanical Engineer to the Sudan Gezira Board—The Sudan Agent in London, Wellington House, Buckingham Gate London, S.W.1, endorsed 'Engineer 2407'.

Chemists at Ministry of Supply Research Establishments i Southern England for (*a*) inorganic analysis (Ref. F.597/52A), (*b*) wor in laboratory providing chemical services, including effluents testing boiler water treatment, and process control (Ref. F.598/52A), an (*c*) physical chemistry research (Ref. F.599/52A)—The Ministry o Labour and National Service, Technical and Scientific Register (K) Almack House, 26 King Street, London, S.W.1, quoting the appropriate Ref. No.

Chief Veterinary Research Officer in the Sudan Veterinar Service—The Sudan Agent in London, Wellington House, Buckinghan Gate, London, S.W.1, endorsed 'Chief Veterinary Research Office 2207'.

Civil Engineers (Main Grade) in the Civil Engineer-in-Chief Department of the Admiralty, Pinner—The Ministry of Labour an National Service, Technical and Scientific Register (K), Almac House, 26 King Street, London, S.W.1, quoting H.149/52A.

Engineers and Physicists (particularly with electronics) in Seni Scientific Officer and Scientific Officer grades (Ref. A.246/52A) Senior Experimental Officer, Experimental Officer, and Assist Experimental Officer grades (Ref. A.247/52A), in the Royal Na Scientific Service, at Experimental Establishments in London, Portsmouth, Weymouth areas and Scotland—The Ministry of Labour an National Service, Technical and Scientific Register (K), Almac House, 26 King Street, London, S.W.1, quoting the appropriat Ref. No.

Junior Hydraulic Engineer, and a Junior Hydrologist, in the Public Works Department, Kenya—The Director of Recruitment (Colonial Service), Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1, quoting Ref. No. CSD.64/7/01.

Lecturer in Agriculture (Crop Husbandry)—The Bursar, Harper Adams Agricultural College, Newport, Shropshire.

Lecturer in Technical Chemistry—The Secretary, Royal Technical College, Glasgow, C.1.

Mechanical and Electrical Engineers in the Air Ministry, for design, operation and maintenance of ground mechanical and electrical works services on R.A.F. and Civil Aviation Stations home and overseas—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting D.290/52A.

Mechanical and Electrical Engineers (2) in the Public Works Department, Sudan—The Sudan Agent in London, Wellington House, Buckingham Gate, London, S.W.1, quoting 'M/E Engineer 1813'.

Meteorology and Hydrology Specialist, a Soils Classifier, an Estimator, a Soil Mechanics Specialist, a Concrete Design Engineer, a Chief of the Civil Engineering Research Laboratory, an Irrigation Operations Engineer, and Junior Engineers (10), to assist in the design, construction and supervision of numerous irrigation and drainage works for the Iraq Development Board—The Ministry of Labour and National Service, (A.S.12, Iraq Development Board), Almack House, 26 King Street, London, S.W.1.

Reader in the Department of Geophysics in the Research School of Physical Sciences, Australian National University, Canberra—The Administrative Officer in the United Kingdom, Australian National University London Office, 27 Russell Square, London, W.C.1.

Research Demonstrator in the Department of Biology—The Registrar, University College, Singleton Park, Swansea.

UTILIZATION OF FUEL IN BRITAIN

THE report of the Ridley Committee[*] is marked by a pronounced cleavage of opinion on one essential point and, in general rather than technical matters, seems to raise fresh issues as well as settle others. The report, however, contains many sensible and unanimous recommendations, and on the whole it carries us a step farther towards a national policy for the use of fuel and power resources. No government will, in future, be able officially to ignore the existence of a continuing rather than a temporary fuel shortage, and policy must be framed accordingly. Nevertheless, the Committee deals a shattering blow at any exalted ideas as to what can be achieved by central direction: its stricture, though implied, on the Ministry of Fuel and Power, is scarcely less severe than are its restrained comments on the warfare between the great nationalized industries which that Ministry is supposed to co-ordinate and which is displayed so frankly in the memoranda appended to this report.

The Committee was appointed to advise on possible measures to promote the best use of the fuel and power resources of Great Britain. It decided to interpret this as meaning that the general aims of a national policy should be: first, to meet in full the demands of the community for the different fuel and power services, when those services are sold at prices which closely correspond to the relevant costs of production and distribution; secondly, to provide for export fuels on such a scale and of such types as can be sold abroad with most gain for the country; thirdly, to promote the maximum economic efficiency in each use of each fuel; and to encourage the use for particular services of the fuel which gives the best return on the resources consumed. The first two of these aims raise questions of pricing policy, and the other two depend on comparative costs. Throughout the report, therefore, the importance of price policy is stressed. Furthermore, it is emphasized that all these aims must underlie a sound national policy at all times, even in the next few years when the gap between supply and demand makes it a first objective to divide what is available between different claimants so as to make the best use of it, and when immediate policy may require measures conflicting with the general aims of policy for the long run.

Reviewing first the prospects for fuel supply, on the evidence it examined the Ridley Committee expects a continued shortage of fuel and power in Great Britain. Future years may bring extra supplies from water, peat, wind and nuclear energy, but no significant return in power supplies is likely within the next few years from the development of power from ocean waves, the internal heat of the earth, solar heat, nuclear energy and other potential sources. Thereafter supplies should be easier, but it appears to the Committee that, to be able to meet in full prospective demands over the next decade, the National Coal Board may have to accelerate and expand its plans for future output. A certain complacency on the part of the Board in this respect left the Ridley Committee quite unmoved and, like Political and Economic Planning in its broadsheet last December, it considers that the Board's estimates of inland demand are too low and its production plans insufficiently related to national needs.

---

[*] Report of the Committee on National Policy for the use of Fuel and Power Resources. (Cmd. 8647.) Pp. v+242. (London: H.M. Stationery Office, 1952.) 6s. 6d. net.

Measures to improve the efficiency of the use of fuel in the next few years are thus essential if the fuel needs of the country are to be satisfied, and in the longer run will always be important as a means of economizing resources. Many constructive proposals are made in the report in this connexion, and to a number of them the Committee attaches special importance. It recommends, for example, that new standards of performance based on achieving a room efficiency of the order of 40 per cent with coal should be determined for solid-fuel room-heating appliances, and it suggests a 100 per cent purchase tax for solid-fuel room-heating appliances and their parts which do not achieve these new standards. It recommends encouragement of the production of high-efficiency open fires of 'utility' pattern capable of easy installation in existing fire-openings and with convection heating and a restricted throat, as well as of simple devices for adapting existing fireplaces, and financial incentives for the installation of fires of the new standards and for improved insulation in new houses.

Subsidies for new house building and the granting of building licences offer obvious opportunities of encouraging such developments, and the Committee thinks that there is a sound case for the provision of some special financial incentive for firms to install fuel-saving equipment. It recommends expansion on more attractive terms of the present experimental scheme, announced by the Ministry of Fuel and Power last March, of government loans for approved fuel-saving appliances. Stokers, too, should be encouraged to raise their efficiency by arrangements for improving their status, and the Committee refers pointedly to the responsibility of government departments and other public bodies for taking the lead in promoting fuel efficiency, and to that of the Railway Executive for planning for increased fuel efficiency and accelerating trials of new forms of traction. A great increase in the service for providing industry with advice on fuel efficiency is recommended; but the Committee wisely emphasizes the responsibility of industry for solving its own fuel efficiency problems, and it recommends that industry should be invited to organize its own fuel efficiency advisory service to supplement that of the Ministry.

There are other sensible recommendations on which also the Committee is unanimous. In view of the greater efficiency of fluorescent lighting, it recommends removal of the purchase tax on fluorescent lighting tubes. The need for training in fuel technology is seen against the background of the general problem of technological education, and it recommends that measures for dealing with the general problem should take full account of this particular need, including the provision of financial aid. There are words for nationalized fuel industries which stress particularly the great importance of pressing forward the investigation of methods for the total gasification of coal, and the Committee lends strong support, as a help both to fuel economy and the export trade, of the early introduction of petrol with a higher octane rating. Unmoved by blast and counter-blast from the rival industries, the Committee notes the costs to the country of overloaded electricity capacity in a period of shortage, and the damage done at all times by smoke pollution, of which the domestic use of coal is a main source. Its impartial analysis of rival claims regarding domestic heating, which is rather kinder than some surveys have been to solid fuel, leads to the conclusion that no fuel or combination of fuels can be selected as the 'best' for domestic fuels in all or most or even 'normal' conditions; the main room-heating and winter-heating services in new houses should normally be provided by solid fuel directly burnt in efficient appliances.

This conclusion is reached on the ground of cost, and it is on this question of costs and prices, especially the price structure for coal, that cleavage of opinion appears. The Committee is unanimous that, from the point of view of the community, the price of coal should not be less than cost. Half of the Committee, however, believes that it should continue to be based on the average cost of production; the remainder would raise the price to cover marginal cost of production by imposing an excise duty of £1 per ton. Without entering here on the merits of argument and counter argument, it might be observed that the price of coal already appears to be sufficiently high to compel attention to fuel economy, and that the proposed excise duty is more likely to penalize the efficient user who has already eliminated waste than those whose extravagance leaves them with a margin for economy. Apart from this, such a proposal prejudices any attempt to devise a price structure based on the quality of the fuel.

It is not, however, this division of opinion that leads the Committee to reject some of the grandiose proposals for the formulation and co-ordination of national fuel policy which were suggested to it i evidence. The Ridley Committee prefers to use tl price mechanism rather than physical controls on fuel consumption to achieve the desired ends, taking into account such factors as the expensiveness of electricity for domestic service at peak hours and its inexpensiveness off the peak. The small specialized Tariffs Advisory Committee, which it recommends should be set up to assist the Minister of Fuel and Power in his general control over the price policies of the nationalized fuel and power industries, is recommended to see that electricity tariffs discriminate, if possible, between peak and off-peak use, while the Committee also recommends that immediate steps be taken to make extensive practical trials of the various methods of measuring or controlling the consumption of electricity during peak hours.

Besides these, the Committee makes the important recommendation that full publicity should be given to the reports and recommendations of the proposed Tariffs Advisory Committee. It rightly attaches the utmost importance to public opinion being well informed on fuel- and power-pricing problems. This s essential if there is to be ready acceptance of price structures determined so as to promote the best use of fuel and power. The Ridley Committee may have also had in mind the restraining influence of such publicity on some of the struggles between the fuel and power industries, and the manifest tendency of uch vast monopolies to seek sectional rather than he national interest.

That is one of the most disturbing features revealed by the Ridley report, and it speaks well for the sound ense of the members of that Committee that they hold firmly and unanimously that the right policy, and indeed the only practicable one, is to leave the pattern of fuel use to be determined by the con-umer's own choice between competing services. The Committee does not believe that direct intervention by the central government would be effective in mproving the pattern of fuel use. Such intervention would unduly restrict the competition between the uel and power industries, which it regards as one ondition if 'freedom of choice' is to produce an conomic pattern of fuel use. The 'rationing' of ouse-coal is accepted as necessary, but only for the present. This, moreover, is not the only factor militating against 'freedom of choice' at present; and he Committee also puts forward three conditions essential for competition to be effective in the desired direction. First of all, the prices and tariffs for fuel nd power should correspond closely to the relevant osts of the particular services provided; secondly, he fuel industries should not impose on consumers any conditions of supply which may restrict their freedom of choice and are not justified by costs; nd thirdly, full and objective information of fuel services and fuel appliances should be made readily vailable to the public.

It will be noted, too, that the Ridley Committee rests its hope for the success of the measures it recommends largely on the willing and continuing o-operation of all fuel users. This presupposes a considerable educational campaign. No doubt the rliamentary and Scientific Committee will give ly attention to this aspect; from that Committee may well come a lead to many professional bodies of scientific men and technologists who could give invaluable help.

There is scope, however, for more co-operation etween the fuel and power industries themselves, nd the Ridley Committee also recommends that the Ministry of Fuel and Power should establish a joint lanning board through which the fuel industries ould concert policy, with the assistance of the Minister. This board would be concerned essentially ith the production and distribution of fuel and ower. Its functions are conceived as embracing ecision as to the selection of projects for investi-ation as possible joint enterprises, reference of the selected problems to the Board's staff for detailed study, the introduction of new projects to the fuel industries and possibly advising on the establishment of organizations to operate joint projects.

The Ridley Committee believes that such a planning oard, in collaboration with the Scientific Advisory ouncil of the Ministry, would accelerate the application of the results of research, and secure necessary routine collaboration at all technical levels. In the last resort, however, the board would, the Committee observes, "depend on the Minister to ensure collaboration when one industry was unwilling to join in a scheme because its particular interests appeared to be prejudiced". Elsewhere, in rejecting proposals made in evidence for the establishment of a single statutory body with executive powers to co-ordinate the activities of the nationalized fuel and power industries as a whole, the Committee observes: "To the extent that co-ordination measures have to be imposed on the Boards (or on any one of them) that, in our view, is a matter for the Minister. In fact we look upon this function of co-ordination and of the control of policy as the main reason for the existence of a Minister of Fuel and Power".

This clear statement that it is the technique or will, and not the power, to co-ordinate that is lacking is an indictment of successive Ministers of Fuel and Power; it is also an indictment of the failure of Britain to deal effectively with the question of Parliamentary control of the nationalized industries, and indeed of the ability of Ministers to ensure that the nationalized industries are administered in the national and not in a sectional interest. That is a failure for which both major political parties must share the responsibility. The Ridley report throws into such strong relief the critical importance of an early solution of this problem of control for the implementation of national fuel policy that it is to be hoped that both political parties will join in the attempt to find a satisfactory solution. Much fresh constructive thought will be required, but given goodwill and an unprejudiced approach the task is not impossible. The Ridley report, itself marked by so much sense and moderation on controversial subjects, may possibly give a further impulse to such inquiry; without it there can be small hope of a national policy effective to eliminate waste of a precious resource, to mitigate domestic hardship and social inconvenience, or to remove the handicap to industrial expansion and economic recovery of which the Federation of British Industries has complained.

ATOMS AND AXIOLOGY

Philosophic Problems of Nuclear Science

Eight Lectures. By Werner Heisenberg. Translated by F. C. Hayes. Pp. 126. (London: Faber and Faber, Ltd., 1952.) 16*s*. net.

ONE summer evening in 1925, a small and very select meeting of theoretical physicists took place in one of the Fellows' rooms in Trinity College, Cambridge. It was a special occasion, and the host may even have 'sported his oak' meanwhile. A brilliant young mathematical physicist, fresh from Munich, Göttingen and Copenhagen, was about to expound his work in the field of atomic physics to a handful of people capable of appreciating it. The speaker was none other than Werner Heisenberg, before long to become a celebrity for his 'uncertainty principle'. Subsequent events have added not only to his distinction but also to the debt which philosophers and scholars everywhere owe him for the profundity of his thought, and for the elegance of his expression. The present book does something to bring these things home to English-speaking readers. 'Something' is probably fair comment, for here is a collection of lectures, originally in German, translated with obvious sincerity but not always with complete *idiomatic* success. To this, some further reference will be made later in this review.

Meanwhile, with engaging humility, Prof. Heisenberg implies that his particular technique, though potent, was not the most beautiful, or even the most unusual. Yet concord upon all essentials concerning atomic configuration was achieved between his results—including the labours of his colleagues—on one hand, and those of Dirac on the other. Encouraging proof of the existence of "a bond unhampered", as Dilthey called it, in reference to seventeenth-century Paris, was near at hand.

History, however, does not repeat itself: these were no 'conversions' to mathematics such as that experienced by Hobbes, and brought about by the presence of Descartes. On the contrary, the twentieth century was to witness a forward surge by the specialists towards a deepening of physical science, and a fresh realization of its implications—for good or for ill—for all mankind.

The reader may well delight in the details elaborated in these eight lectures; but he will probably be the better rewarded if he takes them for what they are assuredly intended to be—an epistemology of Nature on the grand scale. An example (lecture 6) appears in the tracing of the beginnings of the modern era with Galileo and Kepler. Certainly there then existed a unified concept of Nature, namely, that conformable to Scriptural revelation. The aim of the men of science, in modern language, was "to find out God, and read Him everywhere". Later, however, as we all know, other motives gained the initiative.

Prof. Heisenberg brings his readers to the edge of the cliff in his last lecture. He almost invites them to look over and keep their heads. "The core of science is formed, to my mind, by the pure sciences which are not concerned with practical applications." Again, science *can* help international understanding, not because it succours the sick and so forth, but because it may direct our attention to a "centre" (call it what you will, the scholastics knew it as the *deus philosophorum*) in harmony with "the fact that the world is beautiful".

Now all this is exactly what one would expect from a mind of the author's calibre. He writes elsewhere of a region wherein science and art are scarcely separable, and, it might be added, "few there be that find it". This theme, laid before a university audience in Gottingen in 1946, was a brave confession to make before the Germany of that year. It may not be without influence over a wider company.

Philosophically considered, two questions arise. One is the relation of such a view as this to the scholastic doctrine of *analogia entis* (to which in structure it bears some likeness). The other is the marked contrast with the essential outlook of the great humanist architects, in the tradition of Vitruvius. They set out, deliberately, to build geometrically to the glory of God and erected many and great domes to declare His glory above the firmament. Taken together, the Thomist conception seems closer to that of Prof. Heisenberg—his "centre" and the visible world, while incommensurable, permi of a balance, enabling decisions to become real an living experiences.

The poise of the author's mind is perhaps bes revealed in his treatment of the age-long Newton Goethe conflict. This occupies practically the whol of lecture 5 and should be read as a worthy companion to the late Sir Charles Sherrington's Denek Lecture of a few years ago.

In the result, the battle was not pointless, but i may be all too easily taken to be so if the dichotom is not fully appreciated. For Newton, colour was t become an exact part of physics: Goethe was no wholly biased against mathematics, but he feare mathematical analysis and (for him) the destructio of the arena of sense-enjoyment. Yet, as Pro Heisenberg remarks, the loftiest science and th poet's vision are not far apart. It is in passage like these that a rare quality of insight stand manifest, to fortify troubled mankind.

Nobody can expect discussions at this level not t suffer in translation (not to mention being wrenche out of the particular circumstances in which the were originally delivered), but certain easily avoidable blemishes are surely out of place. Examples ar "experience" for "experiment", "apprehensible" fo "comprehensible", and [mental] "deformation" fo "deformity". They do not mislead, but merel annoy: one looks forward eagerly to their correctio in a later edition.

In a sentence of impressive restraint (spoken a Göttingen), these lectures end with a precept akin t the famous one of Wittgenstein—"Whereof one canno speak, thereof one must be silent".

F. I. G. Rawlins

CLINIC AND SOCIETY

The Psychology of Pierre Janet

By Elton Mayo. Pp. ix+132. (London: Routledg and Kegan Paul, Ltd., 1951.) 8s. 6d. net.

It is much to be regretted that the work of th eminent French psychiatrist, Pierre Janet (185 1947), was overshadowed during his lifetime by th of his greater contemporary Freud and, consequent is little known in English-speaking countries. W are therefore grateful to the late Prof. Elton May for his concise introduction to some of Janet's ideas Prof. Mayo addresses himself, not to the student o medicine or psychiatry, but chiefly to students o social and industrial administration, and he confine himself to theories of Janet which are relevant t these areas of activity. His aim is to show how th clinical study of individual psychopathology ma help us to understand how a person's social role become disorganized. He is concerned, of course with the psychopathology of everyday life, not th disorders of the psychotic safely tucked away in a institution.

Taking as his point of departure Janet's view tha "social actions are the most complex human activit and that the costs exacted by adaptation to th individuals around us are by far the heaviest" (p. 90) he proceeds to trace the various ways in whic obsession stultifies or distorts social action. He distinguishes two kinds of obsessive formula, one bein "The world is hostile, let me attack it", and th other "The world is dangerous, I must be careful" nd he devotes his analysis mainly to the second, which he thinks is much more common.

His theme, accordingly, is the social and intellectual neffectiveness of the obsessive person. Beyond a eference to the fact that Janet saw in the obsessive's difficulties a failure to develop in early life the skills necessary for ordinary social communication, the discussion avoids the etiology of obsession and attempts rather to elucidate its nature and effects. Since nearly every intelligent person suffers obsessive pisodes from time to time, the personal and social disruption caused by them must be of interest to all those concerned with human organization.

Janet's interest in the study of hysteria led him to revise his "method of distraction" and to develop his theory of the dissociation of the personality into primary and secondary selves. Retraction of the field of consciousness and dissociation he held to be the two characteristic features of the hysteric. This work gave him an appreciation of the complexity of the attentive act and enabled him to describe with great insight the nature of obsession, though he realized that he was now dealing with disturbances f a different order. In his studies of obsession he shows that every successful act of attention presupposes an ordered background of contributory eflexes and skills. On the interplay between acts of attention and reflective thinking, which gives unity to experience, depends the capacity for decision and ction. It is in the attentive act, according to Janet, hat the obsessive's disability manifests itself.

The reader may be somewhat surprised to find that Prof. Mayo omits any reference to the work of the late H. S. Sullivan who, more perhaps than any other modern psychiatrist, succeeded in synthesizing many of the ideas of Freud and Janet. Janet's notion of retraction of the conscious field becomes, in Sullivan's hands, the "principle of selective inattention". Sullivan supplements this principle with his important heory of "prehension", or perception without awareness (which I have elsewhere suggested needs to be ompleted by introducing a concept of 'apprehension', that is, apperception without awareness). In the writings of Sullivan, Janet's ideas seem to have so r found their most astute elaboration.

JOHN COHEN

FISH AND FISHERIES OF AUSTRALIA

Fish and Fisheries of Australia

By T. C. Roughley. Completely revised and enlarged dition. Pp. xv+344+81 plates. (Sydney and London: Angus and Robertson, Ltd., 1951.) 50s.

MORE than thirty years ago, Mr. T. C. Roughley published a book entitled "Fishes of Australia and their Technology", illustrated with sixty-eight colour plates of common Australian fishes. That book has long since been out of print and unobtainable; but a continuing demand for it has induced the author to write a new and larger volume—"Fish and Fisheries of Australia"—which is now available. The Publishers' description of the new book as a "completely revised and enlarged edition" of the former one seems scarcely accurate.

The book is in two parts. In Part 1 the occurrence, habits, edible qualities and commercial or sporting mportance of more than a hundred and fifty kinds of fish are described in detail and there are brief references to many more. In order, no doubt, to keep the book within reasonable limits of size, little information is included from which identifications can be made; for this the reader must rely on the plates. These are all of very high quality; but they are relatively few in number, and the absence of precise descriptions of distinguishing features limits the value of the book.

Part 2 is concerned with the industry and sport. The annual value of Australia's total fish production is small—less than one-fiftieth of that of the United States. Mr. Roughley's explanation is that "the southern hemisphere lacks the vast concentrations of fish characteristic of northern hemisphere waters", although he also admits that Australian exploitation of her pelagic fishes could probably be greatly stepped up. He offers little hope of any great expansion of demersal fishing, for already some of the most important estuarine and offshore demersal fishing grounds are being overfished, and conservation rather than expansion must be the future policy. In fresh waters, pond culture, which has not yet been tried to any great extent, is believed to offer possibilities, and the fisheries departments of both New South Wales and Victoria plan to investigate them.

Many other fishery activities are dealt with, including shark fishing, big-game angling, spear-gun fishing and fish canning. An interesting final chapter briefly describes some native fishing methods, several of which are still practised by Aborigines in northern Queensland, where the influence of the white man has not yet penetrated.

The author has gallantly attempted to present an Australian rather than a State picture. The attendant benefits of using so broad a canvas more than outweigh the disadvantages—which are many—and the book should have a ready sale in Australia, despite its high price. It should, however, be supplemented as soon as possible by companion volumes dealing in much greater detail with regional fish faunas and their fisheries.

G. A. STEVEN

SURVEY OF HORMONES

Hormones

A Survey of their Properties and Uses. (Published by direction of the Council of the Pharmaceutical Society of Great Britain.) Pp. xii+220. (London: Pharmaceutical Press, 1951.) 35s. net.

THE publication of a volume of some two hundred pages, which sets out to survey the properties and uses of hormones for "pharmacists, medical practitioners, students and other interested persons", raises hopes of a general review which would necessarily be compressed but would bring together the scattered contributions from different branches of science to the problems of endocrinology. Perhaps no one man could successfully write all such a book, and it might have to be a composite production, under the guidance of an editor with the necessary breadth of view. This book, with four named contributors, seems to have had no editor other than the anonymous writer of the preface, which, ominously enough, begins with a quotation from Starling in which ὁρμάω is misprinted ὁρμάω.

The result is a collection of articles pitched at different levels, making independent approaches to different aspects of the same subject, entirely without evidence of co-ordination. Many reiterations of summarized statements might have been avoided by cross-references, and an editor might have discovered, for example, that in spite of repetitive statements about propylthiouracil the chemical formula had not been given. The illustrations are a curious mixture of the frankly popular, such as the frontispiece, and the technical. Some of the sections are competently written; but each author seems to have had a different view of the educational level of his potential reader.

The chemistry of the steroid hormones is reviewed in the tight and abbreviated style associated with the "Annual Reports on the Progress of Chemistry" (and, rather surprisingly, the system of nomenclature is one abandoned by the Chemical Society four years ago). Dr. C. W. Emmens contributes a brief chapter on "Standardisation", but it is disappointing to find that in at least one instance, adrenocorticotrophic hormone, the information is far from up to date—in fact, less so than in the book on hormone assay which the same author edited and which was published in the United States in 1950. There is a section on "Action and Uses", perhaps necessarily superficial, and a chapter on "Pharmacy". The section on "Physiology" is an example of the worst type of scuffling and inaccurate compression. This may be illustrated by one quotation. Of the adrenal cortex it is stated: "Twenty-eight crystalline steroids have been isolated from the cortex. In 1934 Kendall *et al.* isolated a crystalline substance capable of maintaining the life of adrenalectomised animals. In 1936 Reichstein obtained from the adrenal cortex a sterol with androgenic properties which he named androsterone. Ingle isolated seven compounds which were effective in relieving different conditions associated with adrenal cortical deficiency, one of the most active being deoxycortone". It would be difficult to find a parallel to such a concentration of misrepresentations of facts.

It would be unfortunate if a book of this quality, appearing under the patronage of a scientific society of standing, should be taken to represent British knowledge and achievement in endocrinology.

R. K. Callow

PROTECTION OF COTTON IN PEACE AND WAR

Microbial Decomposition of Cellulose

With Special Reference to Cotton Textiles. By R. G. H. Siu. Pp. xi+531. (New York: Reinhold Publishing Corporation; London: Chapman and Hall, Ltd., 1951.) 80*s*. net.

Few textile problems owe so much to the expansion of our knowledge of cellulose and the fibres of which it is the major component as the growth of micro-organisms on cellulosic textiles. It is only necessary to compare the information available when the Fabrics Co-ordinating Research Committee of the Department of Scientific and Industrial Research began, in 1920, the first organized attempt to ascertain the causes of decay of cellulosic fibres, and to assess the value of preventive measures with the extensive literature of to-day, in order to realize the progress that has been made in the intervening period.

In peace-time, the textile technologist is content to protect cellulosic textiles against the growth of moulds at the humidities and temperatures to be expected during transport to, and storage in, tropica climates. The conditions rarely permit the growth o bacteria or even of the moulds which decompos cellulose, so that his main concern is to preven disfigurement. In service, chemical tendering by ai light and moisture is a more potent source of damag than microbial tendering, with the notable exception of fishing nets and lines and filter cloths.

In time of war, particularly in jungle warfare, us may be severe enough to reverse the relative importance of chemical and microbial tendering. Thi prospect has dominated the approach of the Unite States Army Quartermaster Corps to the problem o lengthening the useful life of textile equipment an has, naturally, tended to colour Dr. R. G. H. Siu' treatment of the subject. Nevertheless, Dr. Siu ha earned the thanks of every worker in the field fo undertaking the herculean task of summarizing more considerable body of work than the title of hi book would suggest. He covers successively th decomposition of cellulose in Nature; the structur and properties of cotton fabrics; the organisms whic have been isolated from them; the microbia degradation of cellulose; and methods of preventin microbial attack, including chemical modification.

The description of the mechanical and chemica processes applied to cotton might have been omitted it is unnecessary if the reader is familiar with textil technology, and inadequate if he is not. For the rest either by choice or by force of circumstance, Dr. Si has provided a comprehensive rather than a critica account. Thus, in Chapter 3 he stresses unduly th occurrence of chemical damage during the mechanica processing of cotton. In Chapter 4, the lists o cellulolytic and non-cellulolytic organisms would hav been more valuable if the taxonomy had bee brought up to date. In Chapter 5, it is not mad clear why the humidity of the atmosphere surrounding a textile may be more important than it moisture content from the point of view of moul growth. More attention might also have been devote to the greatly varying moisture requirements o different moulds, particularly as some of those whic decompose cellulose develop freely only at a ver high relative humidity. In Chapters 6 and 7, th comprehensive account of the mechanism of th degradation of cellulose is inevitably rather spe[illegible]lative, for many of the observations are contradictor and often lack adequate descriptions of experimenta materials and techniques.

The remaining chapters (8–12) are accounts o methods of biological testing and of the preventio of microbial attack, either by the use of antiseptic or by conversion of the cellulose into suitabl derivatives. The search for new antiseptics i described very thoroughly; the author's reliance o the soil burial test as the criterion of efficiency lead him, however, to reject treatments which hav proved valuable for specific purposes and to accep treatments which may be open to objection on othe grounds. As the soil burial technique is accepted a a satisfactory prediction of field behaviour, it i disappointing to find no assessment of the relativ importance of microbial and chemical tendering i the many practical uses of cellulosic textiles.

Dr. Siu has provided a book of exceptional valu to the specialist in any section of the field he ha covered; its merit is enhanced by the very comprehensive bibliographies appended to each chapter It is not, however, a book for the industrialist wh seeks a ready guide to the solution of his problems

The British National Bibliography Annual Volume 1951

Edited by A. J. Wells. (Published by the Council of the British National Bibliography, Ltd., British Museum.) Pp. ix+954. (London: J. Whitaker and Sons, Ltd., 1952.) £8 net.

THE objects of the British National Bibliography are to list every new work published in Great Britain, to describe each work in bibliographic detail and to give the subject-matter of each work as precisely as possible. The work is carried out at the British Museum by a team of fully qualified bibliographers. The first annual volume, which is classified according to the Dewey Decimal Classification, is provided not only with a full author, title and subject index, but also with a preface including some hints for tracing information which should smooth the path of the novice in bibliography. The fullest information about a book is given in the Subject Section; information in the Alphabetical Section is limited to author's name, short title, publisher and price.

The value of this Bibliography lies in the authoritative, full and accurate description of each book and in the detailed subject index, which facilitates the finding of books on the most specific subjects. On that it has met such tests as a leisurely examination and one person's experience has been able to apply, and its production appears to be reasonably in keeping with the scale and claims of the enterprise, though its price must restrict the use of the bibliography by the smaller libraries and by individuals. A few classes of publications, namely, cheap novelettes, periodicals (apart from the first issue of a new periodical and the first issue of a periodical under a new title), musical scores, maps, and the less significant Government publications, are omitted. On the last, the term 'significant' appears to be interpreted generously, for there are listed such minor papers as the White Papers on Higher Technological Education, issued last September, on the Future of the Overseas Food Corporation, and on Government Scientific Organization in the Civilian Field, as well as the annual reports of most departments or organizations of interest to scientific workers.

The Earliest Stages of Delinquency

A Clinical Study from the Child Guidance Clinic. By H. Edelston. Pp. vii+200. (Edinburgh and London: E. and S. Livingstone, Ltd., 1952.) 10s. 6d. net.

IT is now generally accepted that crime is the product of environment rather than inheritance. There are some factors—such as mental deficiency—which may be inherited and influence behaviour, but even with these good environment is able to prevent antisocial behaviour in the majority of cases. If environment is of such importance, it is essential that we should make the greatest possible effort to correct it as soon as there is evidence that it is having an evil effect on conduct. It is here that a child guidance centre is of such importance. The result of experience in this work is described by Dr. H. Edelston in his excellent book "The Earliest Stages of Delinquency". He states in the preface that "It is my claim that in this study I have introduced the new 'Psychiatric' approach without losing sight of traditional moral standards". In reality, it is doubtful whether any psychiatrist ever does neglect completely such standards, since he has to adapt his patient to society; but among the lay public the psychiatrist's emphasis on adjustment by removal of disrupting emotions rather than suppression of the personality in accordance with a moral code is sometimes misunderstood.

Dr. Edelston's book is divided into three parts. The first is concerned with the nature of misconduct and the use of the child guidance clinic; the second with treatment at home, by removal from home, and with those cases of severe characterological disorders which are unresponsive to the present modes of therapy. The third part is concerned with the actual administration of treatment and with practical procedures.

The author is the director of the Bradford Child Guidance Clinic, and obviously has had wide experience in this type of work. The book makes an excellent introduction to the problems of delinquency and should certainly be read by all who contemplate dealing with it. It would also be valuable to those interested more broadly in the nature of crime. If only such works were widely read we should have fewer wild statements on the imagined beneficial effects of pet remedies which have already been discarded as useless, and more real effort to cure those in need before they become hopeless recidivists.

CLIFFORD ALLEN

The Story of 100 Years of Phosphorus Making, 1851–1951

By Richard E. Threlfall. Pp. x+400 (58 plates). (Oldbury: Albright and Wilson, Ltd., 1951.) 25s.

FOR a century the firm of Albright and Wilson has been virtually the only maker of phosphorus in Great Britain, and the story of the introduction of the technical process, of its modification by the use of the electric furnace, of the collateral industries which have developed from it, and of the participation of the firm with others within the scope of its interests in two World Wars, could obviously make an interesting book. The task of producing such a book must have been difficult. Unpublished records and published material, personal details of the many who contributed to the success of the undertaking, and the traditions of the firm, have all been drawn upon. The associated companies, such as those at Niagara Falls and in Canada, come into the story. The book is well written and handsomely produced, the illustrations and plates, some in colour, being especially noteworthy. The book is interesting to read and also gives a valuable survey of an important branch of chemical industry.

Coal, Coke and Coal Chemicals

By Dr. Philip J. Wilson, Jr., and Dr. Joseph H. Wells. (Chemical Engineering Series.) Pp. ix+509. (London: McGraw-Hill Publishing Co., Ltd., 1950.) 68s.

THIS volume is intended as a text-book for those interested in carbonization; but its main emphasis is on the coke-oven industry in the United States. It is for this reason that the book has limitations for those requiring a general survey, including British and European practice.

The early chapters deal with the combustion of fuels, the origin, classification and properties of coal, and with laboratory and small-scale tests for the selection of coking coal. Detailed descriptions and drawings are given of coke-ovens in the United States, followed by a review of the chemical and physical changes taking place during coking, and a survey of the properties of metallurgical coke. Useful tables are provided of statistics up to 1946 of the coke-oven industry and the disposition of products, and modern trends are reviewed. In one appendix there is a list of all the carbonization plants in the United States.

About one-third of the book is devoted to the recovery and utilization of by-products. This section is informative and gives a very useful survey. The account of the gas industry is limited to some seventeen pages, and it is here that the book fails to give a balanced picture of modern gas-works practice. Reference is made to the growing interest in the United States in low-temperature carbonization; but processes operated within the United Kingdom are not described.

The book fulfils a useful purpose in reviewing the carbonization industry in the United States; it has endeavoured to cover a wide field in a limited space with considerable success. The printing and reproduction of diagrams and photographs are good.

A. C. MONKHOUSE

Tests for Colour-Blindness

By Prof. Shinobu Ishihara. (Published for Nippon Isho Shuppan Co., Ltd.) Tenth completely revised edition. Pp. 27+38 plates. (London: H. K. Lewis and Co., Ltd., 1951.) 75s. net.

PROBABLY the best known of the confusion chart tests for defective colour vision is the Ishihara series, in which the subject is required to read a number made up of coloured dots printed against a background of a different colour. By the appropriate choice of colours, the various charts have been designed so that the colour defective may either misread the number or fail to read any number at all. The charts may also be a guide to the type and degree of defect depending on the mistakes made by the subject.

During the Second World War, the charts were unobtainable from Japan, and Messrs. H. K. Lewis and Co., Ltd., produced an English edition which proved a very effective substitute. Now a tenth Japanese edition has been produced and is obtainable from Messrs. Lewis, who are acting as agents for the Japanese publisher, the English edition having been discontinued. The underlying principles of the charts are sound, and the merits of different editions depend on how successfully the quality of the colour-printing is maintained. Extensive tests carried out a few years ago in the United States showed significant variations between different editions, and only time will show how the new edition ranks with the old. In some of the charts the colours are darker and more saturated than in the earlier sixth and seventh editions, so that some inconsistency in the subject's reactions may appear. One or two new charts have been added which increase the versatility of the test, and perhaps, in a future edition, charts for testing tritanopia, the blue-green deficiency, could be included.

W. D. WRIGHT

Name this Insect

By Eric Fitch Daglish. Pp. xxvi+294+64 plates. (London: J. M. Dent and Sons, Ltd., 1952.) 15s. net.

IDENTIFICATION of insects is a difficult subject for the non-specialist, the species being so numerous—more than twenty-one thousand in Britain—with many closely alike. Most popular books offer illustrated descriptions of a selection, through which laborious search is frequently necessary. "Name this Insect" is a notable attempt to make the search swifter and more direct.

Attractively written and produced, it begins with a simple exposition of structure and metamorphosis. There follows a key to major groups of insects; thence the quest is directed to the appropriate chapter, which contains a general account of the group, and a key to the adults of a good selection of species (more than seven hundred altogether). The keys are largely non-technical, and opposite each species is a brief description with notes on habits, habitat, etc. Most of the 430 or so illustrations, of which more than eighty are in colour, are good and many excellent, but some are a little inaccurate.

The book will be useful to those for whom it is intended, but there are two inevitable criticisms. First, if a convincing identification is not achieved, the inquirer does not know if this is because he has somewhere made a mistake, or because the species has not been included. Second, the designed simplicity and breadth of field of the keys entails a lack of precision, and identifications will sometimes be incorrect. Careful checking with descriptions and illustrations is essential, and, unless these clearly fit, specialist books should be consulted if certainty is desired. Unfortunately, a list of these is not provided.

B. D. MORETON

From Atoms to Stars

By Dr. Martin Davidson. Third edition, revised and enlarged. Pp. 280. (London: Hutchinson's Scientific and Technical Publications, 1952.) 18s. net.

EVEN a short compendium of modern astronomical facts, theories and methods must perforce be presented fragmentarily in so small a book as this one of Dr. Martin Davidson. Items that especially interest the author, such as atom structure, comets, meteors and tidal theory, are represented by larger fragments. The whole of the universe beyond our local galaxy receives but a small fragment, as does the subject of stars, other than Cepheids, which are intrinsically variable. Some fragments seem to be missing, notably the interpretation of spectra in the light of atomic physics, the principle of the spectrohelioscope and spectroheliograph and others on which so much present-day astronomical knowledge is based.

Nevertheless, in spite of an unbalanced effect, slips, misstatements and inadequate proof-reading, the book will help the reader whose interest in such matters has lapsed to bring himself up to date in certain particulars, especially if he is of a mathematical turn of mind. Assuredly the reader will not have to complain that this department is represented by an inadequate fragment; indeed, if he does as the author suggests in the preface to the first edition, and checks the mathematics for himself, he may spend some profitable hours.

Commendable features are the bibliography and the index.

F. M. HOLBORN

Chymia

Annual Studies in the History of Chemistry. (Edgar F. Smith Memorial Collection.) Vol. 3. Henry M. Leicester (editor-in-chief). Pp. ix+251+15 plates. (Philadelphia: University of Pennsylvania Press; London: Oxford University Press, 1950.) 36s. net.

THIS volume contains thirteen papers dealing with various aspects of the history of chemistry and alchemy. Those on Lavoisier's apparatus, early American chemical societies, and on a comparison of Boyle the chemist and Bayle the historian, may be mentioned as examples of the wide range of interests. The publication has taken its place among the journals dealing with the history of chemistry, and the standard of the articles is being maintained.

CONSTITUTION OF COAL AND THE FORMATION OF COKE

By Dr. W. A. KIRKBY and Prof. R. J. SARJANT, O.B.E.

Department of Fuel Technology, University of Sheffield

A PRELIMINARY investigation here described, which was initiated in this Department in 1947 nd carried out by D. K. Datta, is concerned with he constitution of coal from the point of view of the nechanism of coke formation and forms part of a ider co-operative series of researches including xperimental studies in carbonization and coke roperties.

Four coking-coal slacks were selected for study, ach being of similar ultimate composition but orming cokes which were known to have shown onsiderable differences in behaviour in industrial ractice, particularly by their use in blast furnaces, upolas and lime-kilns. The composition of the oking slacks is given in Tables 1 and 2.

TABLE 1

Coking slack	Coal seam origin	Colliery	Ash-free dry composition (per cent) Carbon	Hydrogen	Nitrogen	Sulphur	Oxygen (diff.)	Gross calorific value
A	Blend of Brockwell and Busty seams	Langley Park, Durham	87·50	5·05	1·60	0·95	4·90	15,530 B.Th.U./lb.
B	Lower Mountain Mine	Scaitcliffe, Lancs.	86·75	4·90	2·00	0·45	5·90	15,370
C	Upper Mountain Mine	Moorfield, Lancs.	84·75	5·15	2·35	1·30	6·45	15,130
D	Blend of Barnsley and Parkgate seams	Thurcroft, S. Yorks.	84·50	5·50	1·85	1·75	6·40	15,010

TABLE 2

Coking slack	Moisture (per cent)	Ash (per cent)	Volatile matter, ash-free dry (per cent)	B.S. swelling No.
A	1·1	9·1	29·4	8½
B	1·5	5·7	30·9	8
C	1·8	10·9	34·1	7
D	1·4	6·8	36·6	7

The general method used is that of selective solvent xtraction of coal under such conditions that as mild esolution as possible is obtained. The experimental rocedures adopted comprise: extraction of the coals ith phenol, pyridine and other organic solvents, and f these extracts further with chloroform, in an tmosphere of nitrogen; chromatographic separation f the latter extracts on activated alumina, eluents sed including chloroform, benzene, acetone and -hexane; and infra-red absorption spectrometric nalysis of the extracts and elutes. The effect of ltrasonic fields[1] of various characteristics upon the xtraction of the coals is also being studied.

In Table 3 values are given showing the relative roperties of cokes prepared from these slacks in an xperimental oven in the Department and also of the ommercial cokes. The 'degradation factor' is an ndex of the physical properties of coke, obtained by he use of a variable-impact shatter machine, and is xpressed as the percentage degradation per ft.-lb. of mpact energy applied. The values given in the table ere obtained in these laboratories by J. E. Littlehild, who developed this impact test for measuring he 'hardness' of coke. It was found, however, in an nvestigation of the relation between carbonizing onditions and the physical properties of these cokes s assessed by this impact test, that the so-called 'hardness' of a coke was affected to such an extent by variation of carbonizing conditions and the position of the actual sample of coke in the oven that the inherent influence of the coal in determining such properties could be masked.

In determining the reactivity by a new method it was found that the parentage of the coal in the coking blend was more definitely related to the reactivity as determined by this method. The reactivity values given in Table 3 were obtained by S. Banerjee and R. J. Sarjant[2] in another investigation in the same series of researches, using a modification of a method suggested by A. C. Dunningham as used in the laboratories at Winnington of Imperial Chemical Industries, Ltd., in which coke is burnt in a sized bed with air supplied at a standard preheat to ignite the bed, the temperature of which is controlled by an external heater. The reactivity is expressed in terms of the ratio of the actual carbon found in the gases to the theoretical maximum carbon content which would be obtained by complete conversion of the carbon dioxide to monoxide, and based in both cases on unit volume of air supplied.

Solvent extraction of the coals. For the present experiments phenol was chosen as the solvent, as it can be obtained in a high degree of purity and can be comparatively easily removed from the extract. Moreover, it has a high internal pressure of 120 cal./ml. at 150° C. and may therefore be expected to give a relatively high yield of extract. The coal samples were ground to pass a B.S.72 mesh sieve, and the extractions were carried out in an atmosphere of nitrogen in a Soxhlet apparatus devised by W. A. Bone and R. J. Sarjant for their researches on coal[3]. Extractions carried out up to 240 hr. gave 31–38 per cent of extract; and as there appeared to be no limiting value of the yields up to that time of extraction, it would seem that the process is not

TABLE 3

Coking slack	Cokes prepared in an experimental oven, carbonizing temperature 1030–1250° C. Degradation factor	Reactivity	Commercial cokes Degradation factor	Reactivity
A	4·2–5·0 × 10^{-3} *	0·606–0·612	3·50 × 10^{-3}	0·573
B	3·12 × 10^{-3}	0·666	6·73 × 10^{-3}	0·642–0·664
C				
D	2·68 × 10^{-3}	0·629	4·03 × 10^{-3}	0·592

* Under the experimental conditions of coking, the full mechanical properties of this coke had not been developed.

merely one of solution, but of depolymerization as well. In a few experiments applying an ultrasonic field (frequency 650 kc./s.) to the coal–phenol mixture, with the coking slack *D*, whereas 35·8 per cent of extract was obtained under the ordinary conditions after a period of 240 hr., after 2 hr. at 50° C. with the field applied the amount of extract was increased to 39·9 per cent.

The phenol extracts (after 240 hr.) were then resolved further by extracting with chloroform, and similar yields of soluble (14–19 per cent on the original coal) and insoluble (16–21 per cent) fractions were obtained for all the coals examined.

Chromatographic separation of the chloroform-soluble extracts. Activated alumina was used for effecting a chromatographic separation of the chloroform extract. After percolation of the solution through the column, it was developed by means of chloroform. There were formed : (i) a narrow yellow zone, about ⅛ in. in depth ; (ii) a zone about ⅜ in. with a gradation of colour from bright yellow to dark brown ; (iii) a greyish-brown zone about ½ in. deep ; and (iv) a deep-brown zone of about ½ in. in depth. Liquid chromatograms were then prepared by eluting with different solvents as follows : chloroform, (i) light-yellow solution from the yellow zone, (ii,*a*) dark-red solution with green fluorescence, (ii,*b*) light-yellow solution ; benzene, (iii,*a*) dark-red solution from the grey portion of the greyish-brown zone ; acetone, (iii,*b*) from the brown portion of the greyish-brown zone ; and *n*-hexane, (iv) from the deep-brown zone.

Infra-red absorption spectrometric analysis of the chromatographic fractions. The instrument used for this purpose was a non-recording Hilger infra-red spectrometer *D*223, with rock-salt prism and absorption cells, and photoelectric relay amplifying galvanometer system. The equivalent slit-width for the range 2·5–15 μ varies from 0·08 to 0·42 μ.

The chloroform extracts and chloroform, benzen acetone and *n*-hexane elutes were examined for the infra-red absorption spectra. There were found to very few bands in the spectra of the chlorofor extracts for differentiation of the four coals.

In the chromatographic elutes, however, numerou absorption bands have been distinguished an tentatively identified, and among them are sever which may be used for differentiating the coals. Th four eluents used differ considerably in their chemic character, and there is, as may be expected, a larg degree of selectivity shown by these eluents in respec of the absorption bands revealed in the differen elutes of any one coal. An analysis of the spect given by the various elutes is given in Tables 4, and 6.

There is to be considered the possibility that th differing proportions of phenol – chloroform-solubl material extracted from the coals may be reflected i the differences between the coals as indicated by th absorption spectra of the elutes. If that were so, th relative amounts of material extracted would lead t the expectation that coals *A*, *B*, *D* would show con siderable similarities in their absorption spectra an that coal *C* would differ appreciably from them. . comparison of absorption bands common to differen groups of three of the coals shows that the numbe of similarities in the group *A*, *B*, *D* is not significantl greater than in any other group.

In view of this, there seems at least a *prima fac* case for dividing the coals into two groups—*A* an *D*, *B* and *C*—on account of the considerable numbe of absorption bands which are common to the coa in each group respectively, as shown in Table 6.

From the information available[4] on the inte pretation of infra-red absorption spectra of organ molecules, the chemical groups in the chromat graphic fractions shown in Table 7 may be tentativ identified from the position of some of the absorptio bands, neglecting their intensities.

In the large number of bands between 9 and 14 the skeletal absorption region, there appear to some which are characteristic of benzene substitutio and condensed aromatic systems.

A notable feature so far is that the differentiatio into groups, based on the absorption spectra of th coal extract elutes, is matched by a differentiatio of the coals in respect of the properties and behavio

TABLE 7

of the cokes made from them. As judged by the figures given in Table 3 for the degradation factor and reactivity for both the commercial cokes and hose prepared in the experimental oven, it will be seen that (with the exception already noted in Table 3) the cokes from coals A and D have lower values han those from coals B and C, that is, the former pair of coals give the harder and more unreactive cokes. Moreover, as regards the relative behaviour of the cokes in industrial practice, those made from coals A and D give a very hot and narrow zone in high-temperature shaft furnaces, as compared with a wider and not so hot zone with the cokes from coals B and C, as well as a higher temperature in cupolas.

From the results obtained so far in these preliminary experiments, it would appear that by the use of these techniques there is possible a differentiation of coals in respect of at least some of the properties of the cokes produced therefrom. A considerable number of coals are now being investigated to see if there can be found in this way an understanding of the fundamental differences in coals which affect their coking properties.

FIRST INTERNATIONAL CONGRESS ON ANALYTICAL CHEMISTRY, OXFORD

THE First International Congress on Analytical Chemistry, under the patronage of the International Union of Pure and Applied Chemistry, was held at Oxford during September 4–9, with Sir Robert Robinson as president. The Congress consisted of twelve sessions, at which forty-three scientific papers, under nine subject groups, were read and discussed, and of four Congress lectures. There were also a trade exhibition of instruments, apparatus and books, and an exhibition of analytical techniques and apparatus.

The success of the meeting was assured from the start by the attendance of about seven hundred chemists from all over the world, some of whom were also able to attend meetings of the Section Committee and Commissions of the Analytical Chemistry Section of the International Union before and after the Congress. The success of the Congress was a worthy tribute to the organizers, the burden of the work falling on Mr. R. C. Chirnside, whose ability was reflected in the smooth running of all the proceedings.

The first of the Congress lectures was given by Prof. I. M. Kolthoff, of the University of Minnesota, who spoke on the "Ageing of Crystalline Precipitates". The 'ageing' to which Prof. Kolthoff referred denotes the irreversible structural changes that occur in a precipitate after it has been formed, of which the classical 'Ostwald ripening', the growth of larger particles at the expense of the smaller, is an example.

Dr. R. H. Muller, of Los Alamos Laboratory, New Mexico, an authority on the subject of instrumentation, spoke on "Research in Analytical Instrumentation". His lecture was not a mere summary but reviewed the possibilities for the future. He discussed the need for perfected instruments such as high-speed, auto-recording balances and instruments for recording refractive index and for photoelectric titration.

Dr. L. H. Lampitt, chief chemist of J. Lyons and Co., Ltd., Laboratories, London, gave the third Congress lecture, with the title "The Value and Economic Importance of Chemical Analysis in Industry and Manufacture". He traced developments from the chemical revolution of the seventeenth century to the present time, and pointed out that to-day the analyst is in a position to aid industry in the main fields of commercial activities, namely, research, process development and process control. He stressed how, in industry, analytical control could, by means of instrumentation, be carried out by relatively unqualified (in the academic sense) persons, and their work could be assessed as a 'bench-rate', a prime charge against the article manufactured.

Finally, Prof. van Nieuwenburg, professor of chemistry in the Technical University of Delft, spoke on "A Contemporary Assessment of the Place of Classical Methods in Chemical Analysis". He spoke of the revolutionary changes in chemical analysis and of the fact that most of the papers read at the Congress were on matters or techniques unheard of twenty-five years ago. The classical methods, which are essentially chemical, may be losing ground, but they still have a future, as the new physical methods need them as a basis.

The papers read at the Congress and the discussions that followed are to be published in the November and December numbers of *The Analyst*, and the whole of the proceedings will be available as a separate bound volume for members of the Congress and others. Consequently, the papers are not here reviewed in detail, but a brief survey is given of the general and specialized subjects discussed.

Five papers on microchemical methods were read, that on the direct micro-determination of oxygen in organic substances being particularly interesting. The apparatus involved was shown at the apparatus exhibition. The micro-gravimetric determination of lead as sulphate and of silver and of mercurous mercury as chlorides was described, the determination of fluorine by the lead chlorofluoride method in compounds containing halogens, sulphur, phosphorus and arsenic was reviewed; and other papers included a description of a countercurrent micro-rotary extractor and a summary of some of the approaches that have been utilized in the development of spot tests, using either organic or inorganic reagents.

In the subject group of optical methods of analysis, there were six papers, covering two sessions. These papers served to illustrate the greater value of 'open' subjects when they are intended for general discussion at meetings. For example, an account of recent advances in infra-red spectroscopic techniques and a paper on the colorimetry of indicators both aroused keen discussion. On the other hand, the papers on ultra-violet absorptiometric determination of arsenic as 12-molybdoarsenic acid (designed for large percentages of arsenic) and on ultra-violet absorption spectra of pyridoxine and related compounds were only of interest to a limited number of people, although valuable in print. In addition, the application of emission spectrography to the routine determination of metals soluble in lubricating oils and the identification by X-ray diffraction of crystalline inclusions in glass were discussed.

The session on the presentation of data moved briskly under a forceful chairmanship. Two papers which were taken together and which aroused considerable interest were those on statistical aspects of analytical determinations, for the detection and correction of sources of error in analytical procedures, and on statistical design in the study of analytical methods, to determine the sensitivity of an analytical method. The third paper in this subject group was on statistical methods in radiochemistry.

The morning of September 6 was devoted entirely to the study of radiochemical methods, and this naturally attracted the chemists working in the newer fields of atomic research. A paper on the determination of trace quantities of the alkali metals by neutron activation analysis claimed that this type of analysis is unique because of its great sensitivity and the fact that other elements do not interfere. Two papers were read on the determination of small quantities of uranium by radioactivation and on precision counting of α-particles, while the preparation of astatine by bombardment of bismuth oxide with helium ions and the solvent extraction of Group *IIIB* metal halides with the aid of radionuclides were also discussed.

The session on organic complexes opened with a paper on some factors controlling the selectivity of organic reagents, in which a product ML_n, formed from a cation M and an acidic reagent HL, if it has suitable physical properties, may serve as a basis for a test for M. The stability of metal 'chelates' in relation to their use in analysis, and 1 : 10-phenanthroline and mono-, di-, tri- and tetra-methyl-1 : 10-phenanthrolines as chelated copper complex cations were studied; also discussions took place on the complexes formed by thorium and uranyl ions with complexones (that is, derivatives of iminodiacetic acid) and on the fractionation of ozokerites and the separation of optical isomers.

A general survey on a fundamental approach to the establishment of *p*H standards opened the session on electrical methods. It was emphasized that *p*H can never possess the absolute significance of a true thermodynamic constant. A method of determining the equivalence point in potentiometric titrations, applicable to instruments calibrated either in millivolts or *p*H units, was said to have been achieved by a numerical manipulation transforming potential-volume curves into straight lines intersecting at the equivalence point. Also included were papers on the replacement of the standard cell and salt bridge by indicator electrodes and the use of non-aqueous solutions in potentiometry, on square-wave polarography, and on polarography of the tetrathionate ion.

It was perhaps significant that nine papers were presented to the adsorption and partition methods group, involving three separate sessions of the Congress. Recent work on gas chromatography was illustrated by the separation and analysis of volatile organic mixtures by displacement chromatography from charcoal columns at 100° C. to an accuracy of better than 1 per cent. It was also suggested that some of the limitations of current chromatographic procedures are overcome by gradient elution analysis, although it has certain disadvantages. The theory of the partition column has been extended to include a compressible mobile phase of a permanent gas, and a method of determining the height equivalent to a theoretical plate of such a partition column has bee given. The apparatus involved was demonstrated a the apparatus exhibition.

The theoretical aspects of paper chromatograph have been studied with the aid of semi-automati instruments based on the square-law behaviour o the ascent or descent of liquid in a strip or sheet o paper. In the field of quantitative inorganic pape chromatography, working details were given for new chromatographic separation of aluminium titanium and iron in three individual spots within time of 330 min. and an accuracy of ± 2 per cent The separation of individual groups of water-solubl extracts of plant and animal tissues was achieved b displacement chromatography on ion-exchange resin a technique that led to the chemical characterizatio of new or unexpected components.

Other papers included one on the use of electro kinetic ultrafiltration to enable the larger molecule of the polysaccharides to enter the porous material used for chromatography, the inability to do so bein normally a serious difficulty, one paper on th applications of ion exchange to analytical chemistry and one on the quantitative determination o tantalum and niobium by inorganic chromatograph on cellulose. This last technique was demonstrate at the apparatus exhibition.

The less-exact science of biological method attracted more limited audiences. Papers in thi subject group included those on the use of protozo in analysis; the use of fungi for determining trac metals in biological materials, whereby increase growth in test fungi was stimulated by the additio of graded amounts of certain metals, from deficienc to sufficiency levels, to a culture solution containin all the other essential nutrients; and the quantitativ assay of pyrogens by the febrile response in rabbit using selected animals according to their body tem perature, body weight, sensitivity, excitation an tolerance.

In the session devoted to general subjects a titri metric method was described for the rapid analys of certain binary liquid mixtures to which alternativ methods may not be readily applicable, and th quantitative determination of organic halides b evaluation of reaction velocity curves was discusse

The exhibition of analytical techniques an apparatus, so efficiently organized by Mr. F. R Jones, was regarded by some as the most importan feature of the Congress. Sir Robert Robinson, i expressing the wish that the exhibits could b retained for his students to see, echoed the thought of many visitors who felt that it was a minor traged to have to dismantle these outstanding exhibit involving as they did a wide range of subjects an craftsmanship and ingenuity of design of a hig order. The usefulness of the exhibition was enhance by the fact that it was staffed at all hours by a enthusiastic team of demonstrators who were qualifie scientific workers specialized in their particular subject and always ready to answer questions or to discus the fundamentals of their exhibits.

It must be clearly understood that selection of th items for description in this article has been quit arbitrary and that only lack of space precludes th inclusion of them all. Some, it is understood, hav been, or are to be, published in the *Journal Scientific Instruments.*

In the case of three of the scientific papers describe above, reference was made to the fact that th instruments or techniques involved were also demon strated at the exhibition. These included: an apparatus for the determination of oxygen in organic compounds, in which the products of pyrolysis of the compound are passed in a stream of oxygen-free nitrogen over carbon at 1,120° C., the carbon monoxide produced being oxidized by iodine pentoxide at 120° C. and the liberated iodine oxidized to iodate and determined by thiosulphate; the use of partition chromatography involving a mobile gas phase and a stationary liquid phase to separate and estimate micro-amounts of volatile fatty acids from formic acid to lauric acid, including all the isomers of valeric acid; and the application of paper strip technique, widely used in organic separations, to inorganic materials covering a very wide range, and the application of the method to separations on a larger scale using columns of cellulose powder.

A popular exhibit was that demonstrating remote-handling devices for radioactive work. It comprised a 'gamma handling cell' for the safe handling of 100 mC. of 1-MeV. gamma-ray sources, tongs for changing tong-heads remotely and a mechanical simulator which is a model of a machine used for accurate manipulation from behind a dense shielding-wall—for example, 2–3 ft. of concrete. An excellent instrument was shown, known as the 'thermistor ebullioscope'. This instrument is intended for the rapid and precise routine determinations of molecular weight. Rapidity is achieved by employing thermistors as short time-constant differential thermometers, and precision by the use of specially designed vapour-jacketed ebullioscopes. Boiling-point elevations, accurate to 0·0005 deg. or less, can be read within about two minutes of adding the solute.

A large and beautifully laid-out exhibition of microchemical apparatus had been organized by the Norwood Technical College (London County Council). This exhibit aroused considerable interest, and the demonstrators were tireless in answering questions. Most of the items were of very simple construction, but the success of the exhibit lay in the fact that the large number of pieces of micro-glassware—methods of stirring in small-scale work, micro-conductometric and other electrochemical techniques and apparatus for small-scale organic syntheses and identification and for general microchemistry—had been made and assembled by a team of enthusiasts working in their spare time.

A fascinating demonstration of new methods of microscopy was organized by Dr. R. Barer, of the Department of Anatomy, Oxford. The subject was, of course, highly specialized, but was of considerable interest to all the visitors who saw the demonstration. There were also demonstrations of a new method of identifying crystalline substances by measurement of interfacial angles, and of the Federov universal stage for determining the optical constants of crystals.

Altogether there were eighty-seven exhibits provided by forty-one individuals, firms, laboratories, research associations or colleges. There was also a trade exhibition of instruments, apparatus and books, effectively organized by Mr. W. Thompson, in which forty-four trade exhibitors were represented.

Apart from the purely scientific side of the Congress, the social side was catered for in a simple but effective manner by the arrangement of tours and excursions. Several informal receptions took place, and a banquet was held in the Hall of Christ Church. The Congress was undoubtedly a great success, and the next one will be awaited with pleasurable anticipation.

ELECTRICAL DISCHARGES IN GASES

AT the recent Belfast meeting of the British Association, a session was held on September 8 by Section A (Mathematics and Physics) which was devoted to electrical discharges in gases. The rather full programme included six papers on important aspects of this subject and a discussion. Prof. A. M. Tyndall presided.

The application of the subject of electrical discharges to-day covers a wide range in physics, including, for example, the investigation of certain properties of matter; the nature of ion–atom reactions; metal surface phenomena in discharge tubes, Geiger counters, and electrical contact devices of every kind; radar switches and the generation of radio-frequency oscillations; high-voltage insulation by compressed gases; and ion sources for nuclear physics. The strong interest was reflected in the full attendance, which included a number of electrical engineers.

The session was opened with a paper by Prof. F. Llewellyn Jones (University College, Swansea) on the electrical breakdown of gases. Discharge phenomena at low pressures, at atmospheric pressures, in highly compressed gases and at electrical contacts appear very different, and different theories have been proposed. Recent work, however, suggests that there are basic principles common to all these aspects. Breakdown at low pressures has been shown to be controlled by primary ionization with a secondary process determined by the nature and geometry of the cathode. For sparks at atmospheric pressure an entirely different theory depending on space-charge effects has been proposed, but recent precision measurements of the ionization currents just prior to sparking show that breakdown in uniform fields at this pressure also is controlled by primary and secondary ionization processes the relative importance of which is controlled by the nature of the cathode[1]. No space-charge effects have been found. With high voltages and compressed gases breakdown appears to be different again in that Paschen's law fails, but this can be explained by the additional generation of electrons by field emission from the cathode. Similar effects can occur at electrical contacts[2]. On the generalized theory proposed, breakdown is a consequence of the development of ionization currents in the gas by primary and secondary processes. No single secondary process always predominates; several can and do occur, sometimes together, sometimes singly. The factors which mainly determine the predominant process in any particular case of breakdown are the nature and geometry of the cathode. In this respect, therefore, the physics of electrical breakdown of gases has much in common with the physics of surfaces.

Dr. C. Grey Morgan (University College, Swansea) described an investigation of cold-electron emission both from electrodes covered with thick oxide layers and from those with thin tarnish films. With heavily oxidized metals, of the type often encountered in heavy electrical engineering, emission of 10^4 electrons/sec. was obtained with low electric fields of about 10^5 V./cm. The fundamental physical process underlying this emission is considered to be the extraction of electrons from ionic sites on the thick contaminating oxide layers always present on surfaces operated in the atmosphere[1]. Another class of surfaces, of great interest in applied and theoretical physics, was also investigated; these were surfaces covered with thin tarnish films of but a few atoms thick. Again, unexpectedly high electron currents were obtained at the low electric fields of 10^4 V./cm., but investigation of the mechanism of this emission showed it to differ from that for thick films. While the mechanism was still a cold field extraction process, it is thought that the electrons actually came from the underlying metal by extraction in an intense surface field set up by the positive ions lying on the surface tarnish film. This effect can lead to a considerable enhancement of the Townsend secondary coefficient. This work directs attention to the important part played by the electrode surfaces in initiating spark breakdown.

Experiments designed to investigate the ionic constituents in gaseous discharges were described by Dr. R. L. F. Boyd (University College, London). The use of the magnetic mass-spectrograph as a probe is impracticable in this work because of difficulties of obtaining radial movement of the probe, screening the discharge from the magnetic field, and collimation of the beam of particles. A new small radio-frequency mass-spectrometer probe which avoids these difficulties was described. This employs a time-of-flight method of discrimination between ions of different mass/charge ratio. With this instrument measurements of the radial variation of negative ion density was measured in oxygen, where the negative oxygen ion concentration is only a hundredth of that in the halogens at the same electron concentration, although the probability of attachment of electrons to iodine atoms and to oxygen is about the same. Preliminary evidence indicates that associative detachment is the most likely process able to account for the sufficiently fast removal of negative ions in oxygen.

Prof. K. G. Emeléus (Queen's University, Belfast) described experiments on the generation of plasma electron oscillations by a hot-cathode discharge. The oscillations (5 cm. $< \lambda <$ 200 cm.) were picked up by a small probe projecting into the glow in the region near the filament. The frequency f of the oscillations was of the same order as that calculated on the assumption of electrostatically controlled vibrations of an electron cloud displaced from an equilibrium position in the discharge plasma, and is given by the Tonks–Langmuir relation

$$f = (Ne^2/\pi m)^{1/2},$$

where N is the number of electrons per c.c., and e and m the electronic charge and mass. With directly heated cathodes oscillations are detected at discharge currents below saturation values. Both with directly and indirectly heated cathodes, the oscillations appeared to be produced over a wide range of tube characteristics. The experimental observations of Merrill and Webb showed that the oscillations were confined to narrow layers of glowing gas near the filament; the primary electrons passing through these sheets were subjected to velocity modulations. These conclusions were confirmed by Prof. Emeléus and his co-workers. Experimental observations support the view that both a primary beam of electrons and a discharge plasma are essential for the generation of oscillations. It is suggested that the complicated motions of the ions and electrons in discharge tubes set up, for example, by the influence of the magnetic field due to the drift current, are analogous to hydrodynamical turbulent flow in fluids. The apparatus used in this work was described by Prof. Emeléus: the discharge tubes could be made easily demountable, as the results were not affected appreciably by impurities in the gas.

Present knowledge of the physical processes which initiate and maintain high-frequency discharges was outlined by Dr. A. H. von Engel (University of Oxford). Experiments covering a wide range of frequencies and pressures were described. At ultra-high frequencies ($\sim 3 \times 10^9$ c./s.) the work of MacDonald and Brown on the limits of the application of the diffusion theory of electron loss and the work of Prowse at atmospheric pressure were outlined. The case where the mean free paths of the electrons are much less than the dimensions of the tubes or electrode separations was next considered: Llewellyn Jones and his collaborators have established a general similarity theorem involving the oscillation frequency as well as the linear dimension of the discharge tube. The work of Gill and von Engel and of von Engel and Francis on the growth of the discharge was then described. The mean free paths of the electrons in these experiments were greater than the dimensions of the discharge tubes, and the field required to initiate the discharge was dependent on the nature of the end walls of the tube on which the electrons impinged. The growth of the electrodeless discharge was shown to depend both on the production of a space charge which reduced the amplitude of oscillation of the electrons until it was less than the length of the discharge tube, and on the establishment of an equilibrium state in which the generation of ions and electrons in the gas equalled the losses to the walls[1,2].

Mr. C. E. R. Bruce (British Electrical and Allied Industries Research Association) considered the case of discharges on both the largest terrestrial and on the cosmical scale; a certain resemblance between photographs of the largest laboratory spark, the lightning flash and solar flares has been found. In discussing the lightning flash, it was pointed out that the earlier recombination theory of the so-called leader stroke is incompatible with the large currents of the order of 1,000 amp. deduced both from magnetic field changes produced by the upward leader strokes from the Empire State Building, New York, and also from changes in the electric field observed to accompany propagation of normal downward leader strokes from the cloud. It was suggested that the leader stroke column has arc characteristics, and that there is a high radial loss of ions from this column by corona loss; the steps by which the leader stroke progressed may represent corona-to-arc transitions. Such a transition may represent the criterion of instability determining the breakdown of very long gaps.

An interesting discussion followed occupying all the time available. Prof. Emeléus discussed certain anomalous inductance and capacitance effects in neon discharge tubes. Mr. S. C. Haydon (Swansea) considered the case of photo-ionization of the gas as a possible secondary ionization mechanism in the breakdown process. He gave the results of calculations on the growth of pre-breakdown ionization currents when photo-ionization was taken as the predominant secondary ionization process. These showed that photo-ionization did not account for the observed growth of currents in air.

Prof. Tyndall raised the question of the possible micro-distortion of the electrode surface due to the sparks used in the experiments on the cold electron emission from surfaces, and pointed out that appreciable disturbance of the surface geometry can enhance the local electric field by producing sharp points. In reply, it was stated that the current in these measuring sparks is severely limited, and experiment shows that no significant distortion of the surface and field enhancement occurs throughout the whole period of measurement. Dr. J. Dutton (University College, Swansea) discussed the significance of the formative time-lag of breakdown, and pointed out that the magnitude of the formative lag depends on the particular Townsend secondary ionization process which is predominant in the generalized theory of breakdown here put forward. Assuming cathode electron emission due either to incidence of photons alone, or with positive ions, calculations showed that in both cases a rapid fall of formative lag from 10^{-4} sec. to 10^{-6} sec. is to be expected as the overvoltage increases from 0 to 2 per cent, although the shape of the two curves differs significantly in detail.

Dr. Boyd discussed further the case of recombination in helium and also gave a fuller account of the radio-frequency mass-spectrometer probe. The high recombination observed in a decaying radio-frequency discharge can be accounted for by the process, proposed by Prof. D. R. Bates (Queen's University, Belfast), of dissociative recombination involving a preponderance of molecular helium ions. This view has been confirmed by measurements with the radio-frequency probe. The reaction involving metastable atoms of helium with a hydrogen molecule was discussed in some detail by Prof. Bates and Dr. Boyd.

CHEMISTRY AND FOOD PROCESSING

A DISCUSSION on food processing, arranged by Section B (Chemistry) of the British Association, took place on September 8 during the Belfast meeting. The food processing industry is steadily developing in Northern Ireland, and Prof. W. Wardlaw's presidential address to the Section, on "The Advancing Front of Chemistry", had dealt *inter alia* with some recent aspects of this industry.

The chair was taken by Prof. H. D. Kay (Shinfield), who gave an introductory paper. He pointed out that a very large proportion of what modern civilized man eats (and much of what he drinks, including many town and country water-supplies) is processed, with the object either of increasing keeping quality, thus permitting the conservation or the long-distance transport of perishable foods, or of rendering the raw food more palatable or digestible or of removing danger of disease. Typical examples were given of foods in each category.

Better food processing would enable the very considerable loss—possibly 15 per cent or more—of human food between production and consumption to be markedly reduced, a matter of real significance in a world where food supplies are increasing less rapidly than populations. Further, many human inhabitants of the world to-day are more-or-less severely parasitized, and efficient food processing would reduce food-conveyed infestation and thus improve general health and working capacity.

The addition to food of chemical substances such as colouring, flavouring and preservative agents and 'improvers' is now under good control in the United Kingdom, and, continued Prof. Kay, there is little evidence that any of those which are at present permitted are dangerous to human health. In fact, some of these additions, like that of vitamins A and D to margarine, are nutritionally beneficial.

In the category of food processing come also the manufacture of new foods, not previously eaten, for human or animal consumption. An example is the production of acceptable human foods from the world's most important crop—grass—and another is the production of palatable, protein-rich food for man and for farm animals by growing yeasts and other organisms on waste carbohydrate (of which a great deal is available) in the presence of inorganic sources of nitrogen and phosphate. Circumstances in the near future will probably compel the active prosecution of further research on such problems.

Prof. Kay also mentioned the development in the United Kingdom of improved methods for the processing of home-produced feed for the winter keep of farm animals. He discussed modern ensilage technique and gave the results of some recent experiments at the National Institute for Research in Dairying, Shinfield, in which different methods for making silage from young herbage crops were compared.

A valuable summary of the science underlying modern bread-making was given by Dr. A. J. Amos (London). He described the biochemical processes involved in the steady production, from the starch of the wheat, of the sugar necessary for gas formation by the yeast incorporated in the dough. Sugar production, which usually requires several hours, depends in part on the quality of the original wheat and in part on the damage caused to the starch granules during milling. The addition of enzymes derived from cultures of *Aspergillus oryzae* is a recent development, now used commercially in the United States, for the correction of low diastatic activity in flour. Slides were shown illustrating the rather complex relationship between the amount of yeast present and the rate of gas production.

In addition to an ample supply of sugar for the yeast, and the satisfactory conversion of this into carbon dioxide, the physical nature of the flour proteins when made into dough must be suitable. Bread made from fresh-milled flour is quite unacceptable; the flour has to be 'aged' for some weeks, during which time changes due to the action of atmospheric oxygen take place, before it is fit for commercial use. In the ageing process the flour also becomes whiter owing to the oxidation of the yellow colouring matter—mainly xanthophyll.

Though beneficial and indeed commercially necessary, the natural ageing of flour is a process which demands the storage under appropriate conditions of several weeks supply of flour. It has been found that the addition to the fresh flour of minute amounts of ammonium persulphate rapidly brings about 'ageing'. Other oxidizing agents have also been discovered which 'improve' the flour by ageing it artificially. The beneficial effect of improvers is due largely to their direct action on the protein. The protein is present in the form of a three-dimensional network with cross-links between neighbouring molecules. 'Improvers' increase the number of such cross-links, probably by oxidizing contiguous sulphydryl groups on adjacent protein molecules to form new disulphide bonds.

A recent discovery which is the basis of a patent is that the improving and bleaching effects, obtained in several weeks by natural ageing, can be brought about in a matter of minutes by distributing atmospheric oxygen, applied by means of a special high-speed mixer, through a batter made from the wheat flour, in presence of a source of oxidases such as soya flour.

Dr. Amos discussed whether the addition of chemical improvers to flour has any harmful effect either on the nutritional value of the bread or directly on the consumer. There is no significant effect on the vitamins of the B complex, and though flour treated with nitrogen trichloride has been shown to cause hysteria in some dogs, there is no evidence whatever that it harms human beings. Nevertheless, because it could be detrimental to some animals, it is probably unreasonable to quarrel with the decision to discontinue its use. The other oxidizing substances used as flour improvers or bleachers have been thoroughly tested in both animals and man, at a level much higher than that in which they are added to bread (one part in 7,000–65,000 of bread) without any ill effects.

Dr. J. A. Lovern (Torry Research Station, Aberdeen) discussed some modern advances in fish processing. Our knowledge of the chemical composition of fish and the changes which occur in fish tissue subsequent to catching has steadily increased, and we now have a rational background for the introduction of improved methods of storage and processing. There is little doubt that any direct use of new chemicals for the preservation or processing of fish would conflict with existing food and drugs regulations.

It is to be remembered that the greater part of the catch obtained by the British fishing industry is in distant grounds—up to five or more days steaming from the home ports. This period, added to the week or so spent in actual fishing, means that much of the catch has to spend two weeks or more in ice before it reaches the consumer. The ice itself is at times made from water containing antiseptics such as hypochlorite, hydrogen peroxide, etc.; one of the most promising bacteriostatic agents is a high concentration of carbon dioxide in the fish-room atmosphere.

There are three broad phases in the course of changes in fish after stowing in ice: first, the period until the fish passes out of *rigor mortis*, during which no bacterial invasion takes place; second, bacterial multiplication and the conversion of trimethylamine oxide (originally present in the fish, but having no odour) into the strong-smelling trimethylamine; third, the progressive breakdown of fish protein, under the attack of bacteria, with the production of ammonia, indole, etc. For practical purposes the second stage is the important one.

While efficient freezing and cold storage of fish completely stop bacterial attack, other types of spoilage can occur, for example, autolysis and atmospheric oxidation. Cytochrome *c* and other respiratory pigments of the muscle have been found powerfully to catalyse the oxidation of fat in cold-stored fish. This oxidation is most effectively controlled by excluding air from the system, for example, by means of a coating of ice, with or without the addition of anti-oxidants.

The process of fish smoking was also discussed by Dr. Lovern. He said that the constituents of wood smoke, as produced in the usual smouldering fire, are not the same as those resulting from the destructive distillation of wood, since the primary distillation products are extensively hydrolysed in passing through the zone of hot damp wood above the smouldering area. The smoke is rich in polyphenols, presumably derived from the lignin fraction of the wood, which are deposited on the fish. When smoked fish is kept for some time, it is not until the concentration of phenols on the fish begin rapidly to decrease that microbiological attack on the damp fish begins. Present research is being directed to a study of the effective smoke constituents, as deposited on the fish, in relation to microbiological spoilage.

The last of the main contributions to the symposium was that of Mr. P. N. Williams (Unilever, Ltd.) on the processing of fats. He reminded the audience that most of the butter and lard consumed in the United Kingdom is produced overseas, so that the main oils and fats processed in Britain are of vegetable or marine origin. Much of the crude oil reaching the United Kingdom for processing (except the whale oil) is of poor quality.

It seems certain that, if the diet of the increasing population of the world is not to have a diminishing fat content, vegetable oils will have to be produced and processed in increasing quantities. At present, most of the crude vegetable and marine oils imported into Great Britain are first refined to edible quality and then further processed into margarine, or into 100 per cent fat products such as 'shortening' (cooking fat) or 'compound lard'.

In refining crude oils, impurities are removed by neutralization, bleaching and deodorizing. Free fatty-acid is removed by the first of these processes, which consists in the addition of alkali—usually fairly strong caustic soda—removal of the soaps so formed and washing with water. Bleaching is usually achieved by shaking under reduced pressure with activated fuller's earth, and deodorization by passing steam through the oil, also at reduced pressure. Subsequent hydrogenation of the oils, to produce end-products with the requisite physical properties, is brought about commercially by passing hydrogen through the warm oil in the presence of carefully prepared nickel carbonate-plus-hydroxide catalyst. If the oils are highly unsaturated, the heat of reaction with hydrogen is such as to require cooling water to be passed in through coils in the cylindrical hydrogenation vessel.

To prepare margarine, a mixture of the hard hydrogenated fats with liquid oil and separated milk (which has been soured under controlled conditions to produce a desirable flavour) is churned. The resulting emulsion is cooled on a rotating drum, and the cooled flakes obtained are afterwards worked to obtain the requisite rheological properties. An alternative modern method, which has the advantage of being continuous, employs an improved form of the 'rotator'—a refrigerated, stainless-steel cylinder, equipped with an agitating system, into which the fat–milk mixture is poured. After shaking, the semi-solid fat is extruded direct to automatic packers.

At a stage before the final churning, vitamin A in the form of a concentrate prepared from whale liver oil, and crystalline vitamin D, are added to the fat. Since a large part of the margarine sold in the United

Kingdom is coloured by the addition of the natural pigment and vitamin A precursor carotene, further vitamin A is produced in the intestine. The nutritional value of such margarine is at least equal to that of butter, and is constant throughout the year. Mr. Williams's paper, like that of the other speakers in the symposium, was illustrated by lantern slides.

In the subsequent discussion, Mr. F. C. Cooke (Ceylon) stated that if the United Kingdom is to secure a steady supply of vegetable fats from overseas for processing, an economic agreement is urgently required which would give some assurance as to future prices to producers of such fats. Another speaker said that, with the advance in the quality of processed vegetable fats and the steadily rising cost of butter, the future of the latter is becoming highly insecure. While there would doubtless be an increasing trend towards the consumption of liquid milk, of dried whole milk and of cheese, butter can scarcely escape the fate of becoming little more than a luxury product.

OBITUARIES

Prof. F. T. Hill

Frederick Thomas Hill, assistant professor of aeronautics in the Imperial College of Science and Technology, London, died on September 24 within a few days of his retirement.

Prof. Hill was born on November 13, 1886. He was apprenticed to the Great Eastern Railway Company and completed his education at Queen Mary College, London. He then worked on engineering design with the Whitehead Torpedo Co., until he joined the City and Guilds College, Finsbury, as an instructor in 1911. He developed an interest in aeronautics and became the first teacher of that subject in a British institution. During the First World War he joined the Royal Flying Corps as a designer and reached the rank of captain.

He joined the newly formed Department of Aeronautics at the Imperial College of Science and Technology as a lecturer in 1920, and he became assistant professor with special responsibility for design in 1924. For twenty-five years this was the only entirely postgraduate department of aeronautics in Great Britain. It was dominated by Hill and Sir Leonard Bairstow, head of the Department. Few of the senior technical people in the British aeronautical world have not passed through their hands, and many will have had their first experience of wind tunnels in the Imperial College 'channel' designed by F. T. Hill. In later years he fought a losing battle for the recognition of design as a postgraduate university subject. However, the more recent generations of students must have benefited from his documented accounts of earlier mistakes.

His particular interest was in the materials of aircraft construction, and the many editions of his book on that subject have become a classic since it first appeared in 1933. He was working on a new edition at the time of his death.

Hill's life was devoted to his work, and this left time for little else. However, he was a founder member of the Institution of Aeronautical Engineers, a Fellow and sometime Member of Council of the Royal Aeronautical Society and a member of many committees of the University of London and of his College. He is survived by his wife, a son and a daughter.

P. T. Fink

We regret to announce the following deaths:

Dr. W. T. Calman, C.B., F.R.S., lately keeper of zoology, British Museum (Natural History), on September 29, aged eighty.

Dr. Philipp Ellinger, formerly of the Lister Institute, on September 12.

Prof. F. C. Lea, O.B.E., emeritus professor of engineering in the University of Sheffield, on September 30, aged eighty-one.

NEWS and VIEWS

Surgery in the University of Otago: Prof. M. Woodruff

Mr. Michael Woodruff, senior lecturer in surgery in the University of Aberdeen, has been appointed Ralph Barnett professor of surgery in the University of Otago, New Zealand. Mr. Woodruff, who is the elder son of Prof. H. A. Woodruff, formerly professor of bacteriology in the University of Melbourne, was born in Britain but educated in Australia, where he graduated at Melbourne in both electrical engineering and medicine. During the Second World War he served in Malaya with the 10th Australian General Hospital, his experimental work on deficiency diets during the captivity at Changi Camp having been the subject of a recent publication by the Medical Research Council. In 1946 Mr. Woodruff was appointed tutor in surgery and lecturer in surgery to dental students at the University of Sheffield, but went to his present post in Aberdeen two years later. He will take up duty in Dunedin early in 1953.

European Cortina-Ulisse Prize: Prof. E. H. F. Baldwin

The European Cortina-Ulisse Prize of a million lire (about £600) has been awarded to Prof. E. H. F. Baldwin, professor of biochemistry in University College, London, for his book "Dynamic Aspects of Biochemistry". This Prize is promoted by the cultural magazine *Ulisse* for the best publication, produced in Europe during the past five years and written in a European language, dealing with an assigned topic (not necessarily scientific). When the Prize was first instituted in 1949, the set subject was the popular exposition of physics or chemistry, and the winner was Prof. John Read, professor of chemistry in the University of St. Andrews. The topic for 1952 was that of biochemistry considered exclusively in its relation to the human organism and with special emphasis on its application to medicine.

International Laboratories in Latin America

A group of scientific workers recently met in Montevideo under the auspices of the Unesco Science Co-operation Office for Latin America in order to study the possibility of establishing international and regional laboratories in Latin America. The meeting stressed the importance of the special conditions existing in Latin America (geographical situation, flora, fauna, etc.) for research work of international interest, and there was complete agreement that such work could best be done by the common effort of the countries concerned through the medium of the Science Co-operation Office. It was decided that the most urgent need was to create a net-work of laboratories of marine biology. Secondly, a certain number of 'service laboratories' should be organized on a regional scale, in the first place by giving some laboratories now operating on a limited national scale the facilities for extending their services to the whole region; the laboratories so selected are to be those dealing with chemical analysis, conservation of microbiological type-cultures, X-ray analysis and scientific films. Finally, the meeting recommended that an Inter-American Institute for Cosmic Ray Research should be set up, with the task of establishing a net-work of cosmic-ray research stations at appropriate altitudes and latitudes, taking into account the stations already in existence; the Institute would have the responsibility of standardizing the equipment and co-ordinating and facilitating the research work in these stations. Those attending the meeting were: Profs. M. O. de Almeida (Brazil), V. Deulofeu (Argentina), I. Escobar (Bolivia), C. Estable (Uruguay), A. G. Domínguez (Argentina), J. Ibañez (Chile), C. Lattes (Brazil), M. S. Vallarta (Mexico), R. Tálice (Uruguay) and F. De Venanzi (Venezuela).

Science for Peace: Statement on the British Atom Bomb

The National Committee of Science for Peace, 49 Flower Lane, London, N.W.7, has issued the following statement: "The recent announcement that an atomic bomb has been made in Britain has been welcomed in some quarters as an illustration of British scientific and technical skill. As an organization of practising scientists, we feel that it serves rather to provide yet another instance of wasteful and dangerous misdirection of scientific effort. . . . To those who argue the priority of defence, we have an obligation, as students of the technical possibilities of modern warfare, to point to the fact that Britain is the most vulnerable of all the great powers to atomic attack. By permitting the installation of N.A.T.O. atomic bases in this country, successive governments have ensured that in the event of war Britain will become the target for a type of offensive to which we are satisfied there can be no practical defensive answer. . . . We call on our government to abandon the path of the atomic arms race. . . . The only practical defence of Britain to-day lies in a programme, to be undertaken by men who have the moral courage to dissociate themselves from indiscriminate massacre as a military policy, with a twofold aim: the use of scientific resources for the development of our own economy and the raising of world living standards, and the sincere and tireless pursuit of conciliation. This organization has never advocated the unilateral surrender of a legitimate defensive weapon. At the present time, the measure of agreement already reached between the powers is, in our opinion, adequate to enable international renunciation of atomic warfare to be achieved without delay, on a basis of reasonable compromise".

European Seismological Commission: Meeting in Stuttgart

During the week September 21–27 the first meetings of the European Seismological Commission, as constituted by the International Union of Geodesy and Geophysics at Brussels in 1951, took place in Stuttgart. The meetings were attended by representatives from twelve European countries, three being from Great Britain. Seismologists from Algeria and South Africa also attended. The main subjects discussed were the seismicity of the European continent, the structure of Europe, the thicknesses of the continental layers as determined by elastic waves set up by explosions, earthquakes and gravity anomalies, near earthquakes in Europe, the motion at the focus of an earthquake and the determination of the depth of focus, seismological observatory work in various European countries, seismogram interpretation including graphical methods, and wave theory. The meeting, the arrangements for which were in the hands of Prof. W. Hiller, was eminently successful, and it is intended to issue a report in due course.

Mathematical Research Institute of Oberwolfach

The Mathematical Research Institute of Oberwolfach (State of Baden), in the French Zone of Germany, has been functioning regularly since it was first opened in 1945 under its honorary director, Prof. W. Süss, of Freiburg (editor of the German Fiat reviews in mathematics), and a large number of informal conferences have been held there, the most recent being one at the end of September on algebra and number theory. All grades and ages, from newly graduated research students to professors of world renown, from inside and outside Germany, are represented in the visitors' book, and the atmosphere of stimulating homeliness, friendliness and freedom to which all testify is due to the quiet management and personalities of the hosts, Prof. and Mrs. Süss. The Institute is attached to the University of Freiburg and receives a small annual government grant for running expenses and equipment. It welcomes all working mathematicians (and their families, as far as space permits) and offers them, at a minimum charge to cover the cost of food, an excellent library, facilities and leisure for relaxation or work, in a comfortable modern country house which is the gift of the State of Baden. It is open all the year round; but, owing to the prohibitive cost of central heating, only a few rooms are in use during the winter. In summer-time, the typical Schwarzwald scenery makes it very attractive, and many of the meetings are held in the open. Proposals for future work are gladly received. Following a suggestion by Prof. Martin Eichler, of Münster, the ideas of Hecke and his school in the field of automorphic functions, algebraic functions and analytical number theory are to be discussed, probably during the second half of this month.

Museum of Leathercraft, London

Considering the great importance of leather in the past and its not inconsiderable value at the present time, it is strange that only recently has there been established a museum devoted to its study and its relation to the development of civilization. The Museum of Leathercraft has now been founded, and is housed in temporary quarters in the National Leathersellers College, Tower Bridge Road, London, S.E.1. Although the formation of a collection is its main purpose, the scope is much wider. Its aims have been set out in the following terms: "The establishment of as complete a historical record as possible of the preparation and use of leather, in all ages and in all countries, by the acquisition of actual examples and of documents, prints and books. The undertaking and encouragement of research into all historical aspects of the subject. The stimulation of research into the best ways of using leather, into possible new uses and into the production of new and special types of leather. The preservation and encouragement of high standards of craftsmanship and design". During the preparatory period, the Museum staged a comprehensive exhibition entitled "Leathercraft through the Ages", planned by Dr. C. H. Spiers and Mr. J. W. Waterer and shown at many provincial centres as well as in London.

Brotherton Collection of the University of Leeds: Annual Report for 1950–51

The sixteenth annual report of the Brotherton Collection Committee of the University of Leeds covers the session 1950–51 (pp. 9; University, 1951) and records the virtual completion of the cataloguing of those books in the English literature section which had not been incorporated in the new catalogue. A start has been made on cataloguing the Romany Collection. On June 30, 1951, the Brotherton Collection contained some 23,726 books, 15,927 pamphlets, 585 manuscripts, 4,106 deeds, 31,555 letters and 25 maps. The first main exhibition of the session consisted of books, manuscripts and other items from the Romany Collection presented earlier in the year by Mrs. McGrigor Phillips. The second exhibition, of English grammars and dictionaries, designed to illustrate their development from the seventeenth to the nineteenth centuries, drew upon the resources of the whole University library, and a third exhibition of books and other documents of 1851 was planned to illustrate the life, thought and literature of a century ago. Some thirty organized parties were included among the yearly total of more than a thousand visitors to the Collection, and the report includes some details of items presented during the year.

Breeding Biology of the Spotted Flycatcher

Using data on the breeding biology of the spotted flycatcher which he had obtained from observations carried out by different investigators at 548 nests, D. Summers-Smith has shown that the normal laying period for this bird in Britain extends from mid-May until the end of July, a small number of birds being double-brooded (*British Birds*, 45, No. 5, May 1952). The average clutch-size decreases from about 4·5 eggs at the end of May to less than 3 eggs by the end of July. A slightly, but significantly, higher average clutch-size occurs in north England and Scotland than in the rest of England and Wales throughout the breeding season. It is probable that the spotted flycatcher can only successfully rear a brood of five young in Britain when the conditions are very favourable. Summers-Smith also reports that no significant variation in nesting success with season has been detected. The average incubation period is 13·2 days and the nestling period 13·4 days.

An Alternative to Regular Clear-Felling in Forestry

Up to the outbreak of the First World War, at which period the bulk of the woods in Great Britain were on private estates, the general forestry method in force was clear-felling and replanting chiefly with conifers. The true practice of sylviculture and correct forest management, as found in Western Europe and enforced by trained British forest officers in India and a few other parts of the British Empire, was at that time little understood in Britain beyond clear-felling and planting and coppice woods. In a recent issue of *Scottish Forestry* (6, No. 1; 1952), the journal of the Scottish Forestry Society, an article appears entitled "The Alternative to Extensive Regular Clear-Felling", by M. J. Penistan, which shows a considerable departure in practice on a large estate in the south of Scotland. On this estate the management recently decided to limit very extensively the existing policy of clear-felling and replanting, especially in the old hardwood areas. As a result of this decision, an interesting situation arose both from the point of view of instructing the forestry staff and securing enough timber to maintain the estate sawmills—a position which has often faced the trained forest officer overseas in the past over far larger areas than the 650 acres maintained by Mr. Penistan. The difficulties in the management were the outcome of the fellings of the two World Wars. The new treatment is described as mixed forestry, and four so-called new rules are drawn up on sound premises for the existing conditions of the crops: to obtain on every acre a continuous yield of the largest volume of timber; to cut only such timber as is ripe and suitable for conversion; to get rid of all uneconomic growth at an early stage in life and to introduce trees of high quality by natural seed or planting; and to secure conditions for adequate recruitment of timber, that is, enough from which to select fine poles to grow to timber. For a private estate the proposed management is a great departure in forestry practice in Great Britain. Mr. Penistan says that his article, showing how this is to be carried out, has been compiled from the notes made after discussions of the necessary steps to be taken. It is a pity that these notes are not reproduced in a rather more lucid form. To the forester who has been in charge of forest areas managed on professional technical lines they will be understandable; but it may be suggested that some rearrangement would appear to be advisable for those who, though they have not had this experience, may wish to follow Mr. Penistan's admirable departure.

Leicester Museum and Art Gallery: New *Bulletin*

Leicester Museum and Art Gallery is to be congratulated on the issue of the first number of a *Bulletin*. It is envisaged that each number shall be a coherent whole, and that all articles shall be linked by some common and fundamental idea. The present theme is "Origin", and the second will be "Growth". Regular publication is not promised; but future issues will appear as the necessary material is forthcoming. Following a general editorial article, several examples of origin are discussed. These are arranged in order of their natural development, the earth, the animal, the artefact, recorded knowledge, and art. The first paper thus describes igneous intrusions in the county of Leicester and is followed by a description of the pentadactyl limb and the changes it has undergone in mammalian evolution. An archæologist then stresses, with illustrative examples, the importance of origin; knowledge is represented by a paper on the early history of the Town Library, and art by a discussion of a drawing of two horsemen by Sir James Steuart.

Reporting Research in Education

In the second pamphlet published by the University of Manchester School of Education (Manchester Univ. Press. Pp. vii+24. 3*s*. 6*d*. net), Stephen Wiseman has provided some useful information for research students who are preparing their material for publication. The first part of the pamphlet deals with the preparation of a thesis submitted for higher degrees in education and includes useful sections on the length and form of the thesis, the general pattern, outline of the research, statement of the problem, review of the pertinent literature, descriptions of the design of the experiment, description of the techniques, statement of the results, interpretation and discussion of the results, how to summarize the conclusions and the setting out of the bibliography. In the second part of the booklet Wiseman examines how a paper should be prepared for publication and deals with such topics as preliminary planning, the form of typescript to be used, the use of tables and diagrams, the question of proofs, the taking of off-prints and typography. The whole pamphlet is well written and would be of value not only to research students in education but also to those who have investigations to report in any academic study.

Petroleum Films Bureau

The Petroleum Films Bureau has recently published its 1952 list of 35-mm. and 16-mm. documentary and instructional films. It contains certain features not found in the previous 1951 list, and included among the new films are "Oil for the 20th Century", "The Persian Oil Dispute", "Grangemouth Project", "Air Parade", "Highlights of Farnborough, 1951", "Model Flight", "Festival Log Book", "XXIst Monte-Carlo Rally 1951", "An Introduction to the Heat Engine", "Machining of Metals", "The Gas Turbine goes to Sea", "Weed Control", and also some additions to the film magazine series. All 16-mm. films are printed on 'non-flam' stock; the 35-mm. films are on 'flam' stock. As previously, films are available free of charge (return postage to be paid) to educational institutions, societies, clubs and the like, and application should be made to the Bureau at 29 New Bond Street, London, W.1.

Colonial Service: Recent Appointments

The following appointments have recently been made in the Colonial Service: E. G. Harmer (senior produce officer, Department of Marketing and Exports, Nigeria), principal produce officer, Department of Marketing and Exports, Nigeria; F. A. Squire (entomologist, Sierra Leone), director of tsetse control, Gold Coast; R. M. Arnold (veterinary investigation officer, Jamaica), deputy director (livestock), Jamaica; K. D. S. Macowan (senior veterinary officer, Kenya), deputy director of veterinary services, Kenya; E. P. Rice (senior veterinary officer, Kenya), assistant director of veterinary services, Kenya; J. G. Ross (veterinary officer, Cyprus), veterinary officer, Uganda; Dr. F. D. Ommanney (principal scientific officer, East African Marine Fisheries), director of the Regional Marine Fisheries Research Station, Singapore; D. R. Brewin and B. R. Tarr, agricultural officers, Tanganyika; E. L. Drake, entomologist, Nyasaland; A. D. S. Duff, plant pathologist, Kenya; L. J. Hart, agricultural chemist, Tanganyika; R. J. Harvie, agricultural officer, Uganda; W. Hirst, botanist (plant pathologist), Uganda; O. T. Roberts and R. A. Sands, agricultural officers, Kenya; A. L. Wharton, plant pathologist, West African Cocoa Research Institute, Gold Coast; A. J. Radford, government chemist, Mauritius; B. Douglas, assistant conservator of forests, Northern Rhodesia; J. A. Seymour, geologist, Somaliland Protectorate; W. Hardie, veterinary officer, Fiji; B. M. Brown, meteorologist, Nigeria; L. J. Dyke, field officer (research), Mineral Resources, Uganda; F. C. F. Wickery, technical assistant, Mineral Resources (Research) Committee, Uganda.

Announcements

Prof. P. A. M. Dirac, Lucasian professor of mathematics in the University of Cambridge, has been awarded the Planck Medal for 1952. This Medal is awarded annually by the Association of German Physics Institutes for special accomplishments in theoretical physics which have a connexion with Planck's work. The Medal was founded some twenty years ago and the first recipient was Planck himself. The award is announced to the recipient each year on Planck's birthday, April 23, and the presentation is made at the autumn meeting of the Association of German Physics Institutes.

A dinner to mark the centenary of Sir William Ramsay (see *Nature*, October 4, p. 554) will be held at University College, London, on October 15. The guest of honour will be H.R.H. The Duke of Edinburgh.

An exhibition illustrating the work on logic of W. Stanley Jevons has been arranged in the Christie Library of the University of Manchester, and will be open during October 15–31. It includes Jevons's original logical machine, loaned by the History of Science Museum, Oxford, and more modern machines.

The Committee of Privy Council for Agricultural Research and Nature Conservation has re-appointed Prof. G. R. Cameron, Sir James Turner and Sir James Scott Watson to membership of the Agricultural Research Council for a further term. The Committee has also appointed, after consultation with the President of the Royal Society, Prof. E. J. Maskell, Mason professor of botany in the University of Birmingham, Prof. P. B. Medawar, Jodrell professor of zoology and comparative anatomy in the University of London, Prof. L. P. Pugh, professor of veterinary medicine in the University of Cambridge, and Prof. J. S. Young, professor of pathology in the University of Aberdeen, to fill the vacancies caused by the death of Prof. F. T. Brooks and the retirement from the Council of Prof. A. C. Chibnall, Sir Thomas Dalling, Sir Alan Drury and Dr. Joseph F. Duncan.

The Manson Lectures for 1952 of the Royal Institute of Philosophy, on the general topic, "Mind and its Place in Nature", will be given at University Hall, 14 Gordon Square, London, W.C.1, on Fridays, at 5.30 p.m., beginning October 17. The speakers will be Prof. J. Z. Young, Dr. C. G. Phillips, Dr. Macdonald Critchley, Dr. O. L. Zangwill, Prof. A. W. P. Wolters and Dr. A. C. Ewing.

The Printing, Packaging and Allied Trades Research Association is holding a conference and exhibition at the Jackson Hall, Westgate Street, Cardiff, on October 27, at which there will be two sessions, on "Research and the Printer" and a "Brains Trust", respectively. The whole programme will be repeated at the Grand Hotel, Bristol, on October 29, where in addition there will be a technical discussion on October 30 and a further viewing of the exhibition. Further information can be obtained from the Association at Patra House, Randalls Road, Leatherhead, Surrey.

ROYAL PHOTOGRAPHIC SOCIETY'S EXHIBITION

THE ninety-seventh annual exhibition of the Royal Photographic Society was opened in London on September 12 for one month and will also be shown in the City Art Gallery of Leeds during October 25–November 23 and in the Art Gallery of Bristol during December 6–31. The exhibition is divided into seven sections: pictorial, scientific, medical, nature, stereoscopic, record and kinematic photography, with a total of 849 exhibits.

Within the Scientific Section, exhibits confined to photographic applications of physics and chemistry are small in number, though not in quality, while entries of biological interest are reasonably well represented. The Aerodynamics Division of the National Physical Laboratory is showing three prints consisting of *Schlieren* patterns of the air disturbances emanating from aerofoils mounted in an air current of Mach number 1·6. Two of these prints are in colour and show the various regions of compression and rarefaction by making use of the familiar technique which employs polarized light for the exposure. P. H. Harris shows an electron micrograph of a sheet of etched aluminium foil in which the etching had eaten away the metal, apparently by boring it out in the form of minute tunnels. A. V. C. Cross is exhibiting a series of photomicrographs in which are shown the gradual erosion of a film of rosin naphtha varnish by sea water. A number of aerial survey photographs by Hunting Aerosurveys, Ltd., principally concerned with the site for a dam in Iraq, are of considerable geological interest. In addition, an aerial photograph of the ruined Palace of Persian Kings of Persepolis gives a strong impression of the beauty and splendour that such a building must have possessed in ages past. One of the biological exhibits by H. J. Howard consists of a series of four photomicrographs of progressively increasing magnification from × 10 to × 350 of the apparently simple bird's feather. First the shafts of the feather, then the barbs and finally the barbules are progressively brought into prominence, the fibres of the last interlocking almost at right angles to produce an intricate and effective protection. The selective absorption of silver on the gills of a freshwater crab is shown in an exhibit by S. F. Bush, yet the particulars of what is clearly a process of considerable interest to the chemist are left unexplained. A good example of phase-contrast microscopy by B. A. Jarrett consists of the micro-organism *Stentor roeselii*, in which it can be seen how movements of the cilia enable the cell to swim. An excellent series of colour transparencies by G. H. McLean shows the effects of five different diseases on the leaves of the sugar-beet plant.

In the Medical Section, many of the exhibits hold more than a morbid interest to the lay spectator, because they adequately describe some cycle or technique rather than illustrate some more-or-less distasteful specimen under an obscure Latin title. For example, a virus culture technique shown by the Institute of Ophthalmology, London, is most clearly demonstrated in a series of pictures in which, starting with an eleven-day old fertile incubated egg, part of the shell has been cut away and the egg inoculated. Incubation was continued for about three days, after which the membrane was covered with virus lesions. Perhaps one of the most noteworthy exhibits is from the Hospital for Sick Children, Great Ormond Street, London, in which photographs of a patient taken as a boy and also as a man forty-seven years later show what was probably the first successful surgical removal of a brain tumour with survival over this period. From the same hospital there is also shown, in another exhibit, the system employed for the identification and recording of the particulars of each patient. The technique employed in testing such antibiotics as aureomycin, chloromycetin, penicillin, streptomycin and terramycin is shown by S. E. Veronique. Small paper disks impregnated with the antibiotic are placed on the surface of agar upon which *Staphylococcus* is seeded, and the clear area around the paper disks in which growth of the organism is inhibited is a measure of the effectiveness of the antibiotic. The Manchester Royal Infirmary is showing how enlargement of a radiograph can prove to be worth while, and illustrates this with × 10 enlargements of pathological bone specimens originally exposed on ordinary commercial fine-grain film. Further exhibits by the Institute of Ophthalmology demonstrate techniques and apparatus for retinography and keratography together with colour prints of the human retina. A series of mounts from Guy's Hospital, London, are interesting in that they record limiting movements of the hand, foot or eye either by taking more than one exposure on the same negative or else registering the pictures showing extremes of movement and making tracings from the separate pictures. Photographs of some of the appliances which come to the aid of a hand deprived of normal movement are also shown by K. G. Moreman.

There are numerous excellent exhibits in the Nature and Record Sections of the Exhibition which make it difficult to review with justice; but perhaps the entries on the life-histories of marsh fritillary, gipsy moth, vapourer moth and emperor moth by S. Beaufoy and J. D. C. Boyes deserve special mention.

MODERN METHODS IN THE TREATMENT OF TUBERCULOSIS

THE figures for tuberculosis mortality (England and Wales) since the end of the Second World War show a marked decline. In 1946 the deaths from respiratory tuberculosis were 19,365; in 1950 they were 14,079. In 1946 the deaths from other forms of tuberculosis (bone and joint disease, meningitis, glandular disease) were 3,485; in 1950 they were 1,890.

The mortality from tuberculosis in England and Wales, moreover (with the exception of temporary set-backs during two World Wars), has been steadily declining since 1912, when the national scheme for combating tuberculosis, now merged in the National Health Service, was established. Even allowing for the potential influence of a hypothetical epidemiological cycle, it is not unreasonable to assume that increased knowledge and wisely directed administration have contributed to this decline.

There are certain methods of prevention, diagnosis and treatment which are powerful allies in the anti-tuberculosis campaign. These are as follows.

(1) *Research.* There is close association of research work in tuberculosis with practical application by clinicians. Important work in this field is done by tuberculosis committees of the Medical Research Council, the Ministry of Health, the Prophit Trust of the Royal College of Physicians, the Papworth Research Institute, the Tuberculosis Association and other research bodies. Studies are being made on immunization with B.C.G.

(2) *Pasteurisation of milk.* It is estimated that 30 per cent of non-pulmonary tuberculosis is due to infection by bovine strains of the tubercle bacillus, almost always conveyed by milk. In England some 80 per cent of liquid milk is heat-treated, and if only the remaining 20 per cent were so treated a further large reduction in these deaths might well follow.

(3) *X-rays.* In the past twenty years the improvement in X-ray technique has helped the diagnosis of pulmonary tuberculosis and the control of collapse therapy. The value of tomography was established by the work of McDougall and Turning in Great Britain. Lastly came mass radiography, which has developed much of late years for the diagnosis of the early case of pulmonary tuberculosis.

(4) *Surgical treatment.* The extended use of artificial pneumothorax from 1920 onwards marked a great advance. It may be associated, however, with certain severe complications, such as air embolism, spontaneous pneumothorax, empyema and bronchopleural fistula. Difficulties also arise in the termination of an artificial pneumothorax, for the lung will not always re-expand. The type of case, a limited lesion, which did well with this treatment is often treated by chemotherapy to-day. Artificial pneumothorax is still of value in appropriate cases, although some practitioners, especially in Holland, have abandoned it in favour of other surgical measures. Pneumoperitoneum is still employed, both as a useful accessory to chemotherapy and as a temporary procedure to prepare a patient for operation; but phrenic crush, which partly paralyses the diaphragm, often permanently limits respiratory function and is seldom advised. R. Laird is of opinion that thoracoplasty (usually done in two stages) has still a definite place in the treatment of pulmonary tuberculosis. In the six years 1944–50, of 580 patients treated in this way there was a mortality-rate of less than 1 per cent per operation, and 72 per cent of these patients were sputum-negative during the two months before their discharge. Various extrapleural and extrafascial operations may be grouped with thoracoplasties. A one-stage operation followed by no deformity is attractive, but the fate of the dead space and its plastic packing has yet to be determined. Cavity drainage is not often done in Great Britain. Excision of diseased lung formerly had a high mortality from the risk of spread of tuberculous infection. Improvement in operative technique and the use of antibiotics, notably streptomycin, have made pneumonectomy, lobectomy, segmental resection and wedge excision safer and of benefit to many patients unsuitable for collapse therapy. In Laird's series, resection of lung gave a sputum-conversion rate of more than 90 per cent, and the mortality among 132 patients so treated was 4·5 per cent. Despite the increased risk, excision in the United States has largely replaced thoracoplasty, and it is an operation which has now a definite place in treatment.

(5) *Chemotherapy.* The clinical application of antibiotics, streptomycin and *p*-aminosalicylic acid is being actively pursued with encouraging results. Many patients with pulmonary tuberculosis are initially thus treated at home, and, consequently, a higher proportion of those admitted to sanatoria for active treatment have become sputum-negative. This favourably influences medical and surgical treatment alike in sanatoria.

Prevention and treatment must go hand-in-hand in the attack on tuberculosis. As infected cases in the community become fewer, so will the prevalence and mortality of the disease further decline. The new methods of treatment here discussed are highly encouraging; but the older and simpler methods of prevention, notification, contact examination, environmental hygiene and good nutrition must be associated with them. CARNEGIE UNITED KINGDOM TRUST

REPORT FOR 1951

THE thirty-eighth annual report of the Carnegie United Kingdom Trust, covering the year 1951*, refers to the impeding of the village-hall building programme by the general restrictions on capital expenditure: work proceeded on twenty-one schemes throughout Great Britain, and grant instalments amounting to £11,679 were paid; a sum of £30,000 remains available for schemes approved before the end of 1947 but still awaiting a starting date.

Sums of £15,000 were allocated to the Family Welfare Association and to Family Service Units for the quinquennium. The former is conducting an experiment in the approach to personnel problems from the point of view of community relationships and also another experiment involving the employment of a specially trained worker to deal with problem families as part of the case-load at one of the Association's centres. The Family Service Units undertake practical work in the homes of problem families and, as a corollary, practical research in close association with the field-work of the separate units now established in some of the larger cities. A grant of £6,000 to Stanley House, a community centre in Liverpool for coloured people and their friends, is for a development plan involving structural alterations and provision of additional facilities to make the centre a house of friendship for everyone, irrespective of colour, class or creed. The Joint Committee on Museums Policy is surveying several provincial museums which have been selected as potential centres for installing experimental demonstration galleries embodying the most modern ideas of the technique of presentation.

---

* Carnegie United Kingdom Trust. Thirty-eighth Annual Report, 1951. Pp. viii+48. (From the Trust, Dunfermline, Fife, 1952.)

The trustees are defraying the cost of twelve small experimental alphabet-into-braille machines, which are to be given an exhaustive trial by the two National Institutes for the Blind and Deaf, and a grant of £2,000 over five years on a diminishing scale has been promised to the newly formed Scottish Institute of Adult Education; also, on certain conditions, £5,000 to the British Association for the Advancement of Science for the adaptation of Down House as a residential centre for scientific work and courses in natural science. The survey of agencies and activities concerned with juvenile delinquency was concluded during the year, and the report is being drafted; Miss E. L. Younghusband's supplementary report on the employment and training of social workers, published in September 1951 under the title "Social Work in Britain", had a very favourable reception. The bulk of the report is devoted to a review of the trustees' policy in regard to music and drama, a field from which they have withdrawn now that it is a statutory responsibility of local education authorities.

ENERGY IN THE SERVICE OF MAN

It is not yet too late to be worth while directing attention to the series of papers presented in Paris last year under the auspices of the United Nations Educational, Scientific and Cultural Organization (Unesco, 19 Avenue Kléber, Paris 16^e). One such theme for discussion is to be proposed annually. The first was "Food and People"; now we have "Energy in the Service of Man", which covers an equally wide field. There is some duplication in the six papers; but this is not very important, as the subject is treated from widely different points of view, the authors being free to express their own opinions.

Sir Alfred Egerton, of the Imperial College of Science and Technology, London, discusses "Civilization and the Use of Energy". This long paper considers energy as a determining factor in the growth of civilization, emphasizing the tremendous effect of the new discoveries in the era following the Renaissance. The extent to which available energy resources are at present utilized is also discussed. There are tables and charts provided, but this very general historical approach does not make easy reading. It provides a background against which the ideas in the other papers can be more usefully assimilated.

Dr. L. C. McCabe, of the U.S. Bureau of Mines, in "World Sources and Consumption of Energy", considers the different forms of energy reserves—those such as coal, oil and nuclear fuels, which will ultimately be consumed, and others like water-power, tides, wind and solar radiation, which are continually renewed. He believes that, even with the present rate of technological advance and ever-increasing energy consumption, the world's annual energy requirements in the year 2000 are not likely to exceed 1 per cent of even the known mineral reserves. There are numerous tables giving precise data.

Dr. G. Eichelberg, of the Federal Polytechnic, Zurich, presents a very thought-provoking paper on the "Utilization of Energy". He emphasizes that solar radiation is the ultimate source of all our energy; the greater part of that which we use is stored as chemical energy, which must be converted to mechanical energy by combustion in a heat-engine plant. Dr. Eichelberg discusses the fundamental thermodynamic relationships and traces the thermodynamic evolution of the steam engine, the steam turbine, the internal-combustion reciprocating engine and finally the internal-combustion turbine. His remark that "for the great air-liners jet-propulsion is therefore scarcely a practical proposition", because of its low fuel-efficiency, is already out-dated. He ends with a mention of the theoretical merits of binary-vapour systems, both with independent and combined circuits, and advocates a more intensive research in the field of solution thermodynamics. There are some revealing statements as to the efficiency of domestic heating and the possibility of greatly improved efficiencies by coupling to industrial plant or the use of heat pumps.

Prof. P. Ailleret, of the National School of Roads and Bridges, discusses "Energy in its International Aspects". Since the geographical distribution of natural sources of energy bears practically no relation to the distribution of human needs, great international exchanges of energy are desirable. He gives very interesting maps which demonstrate world movements of fuel, continental electricity grids and oil and natural gas lines. He gives facts to show the scale on which energy exchanges exist at present. He shows that a continental area is usually adequate to form an economic grid—little gain would accrue from intercontinental linkage. Prof. Ailleret discusses the convenience of different forms of energy from the point of view of transport; the ease of transport of oil and gas and the difficulty of transporting electricity economically over great distances are remarkable. He also considers energy storage: it is, of course, cheaper to carry alumina to the electrical generating station and then transport back the aluminium produced from it than to transmit the electrical power to the mineral source. The aluminium metal, having a higher 'potential' energy content than the alumina, represents a form of energy storage. This paper is full of interesting ideas: it is not so much the facts that are new as the way in which they are presented and their interrelation shown.

Prof. M. S. Thacker, of the Indian Institute of Science, Bangalore, treats "The Role of Energy in the Under-developed Areas". This is also a long paper, and the typographical arrangement is different from that of the remaining contributions. It does not make easy reading, largely because of the author's elaborate prose style. He discusses the comparative development of the countries of the world and the distribution of resources among them, considering the factors responsible for the backwardness of various countries. Finally, he outlines a programme of development, including technical and material assistance. He supports his arguments with many tables and much statistical data.

Prof. F. E. Simon, of the Clarendon Laboratory, Oxford, considers "Energy in the Future". Like Prof. Ailleret's paper, this is a challenging and readable document, which ought to provoke much thought and discussion. This is exactly what was intended of the series. The exposition is masterly in its lucid and scholarly approach, while retaining and exploiting the inherent interest of its theme. After dividing energy into its two main categories of 'free' or ordered energy and 'heat' or disordered energy, Prof. Simon recalls the limitations and difficulties inherent in converting the latter into the former, as determined by the second law of thermodynamics. This leads to a consideration of the heat pump as an alternative use of the refrigeration cycle. He then discusses the present efficiency of energy utilization in domestic heating and in industry: there are some striking and unpalatable truths revealed here—it is a pity that more of those recently engaged in controversy on these topics had not read Prof. Simon's paper. The next section surveys available power sources: the wind, earth and ocean heat, the tides and water-power. A carefully reasoned account is then given of the prospects of obtaining significant quantities of energy from nuclear sources and from solar radiation: the conclusion is reached that, from a 'peaceful' point of view, the prospects of the latter are fully as great as those of the former, and that an equivalent amount of research ought rightfully to be expended upon it. It is a sobering thought to consider what the ratio actually must be. Finally, Prof. Simon summarizes his views on the prospects for the near and distant future.

Each of the papers has a bibliography attached, and a more extensive English bibliography, prepared by the Department of Scientific and Industrial Research, is included as a final contribution. It will be seen that the papers presented vary from the very general to the rather detailed; but the most successful are those which strike a mean between these extremes. It would be valuable if they could be made available in more permanent form at a reasonable price.

R. H. MACMILLAN

PHYSICS IN THE UNITED STATES

ANNUAL MEETINGS OF THE AMERICAN PHYSICAL SOCIETY AND OF THE AMERICAN ASSOCIATION OF PHYSICS TEACHERS

THE annual meeting for 1952 of the American Physical Society was held at Columbia University, New York City, during January 31–February 2. The attendance reached the unprecedented figure of 2,215, and approximately three hundred papers were contributed. The twenty-first annual meeting of the American Association of Physics Teachers took place simultaneously at Barnard College. At the joint ceremonial session of the two bodies held in the afternoon of February 1, the retiring presidential address of the Society was delivered by Dr. C. C. Lauritsen, of the California Institute of Technology, who took as his subject "Some Investigations of Light Nuclei"; the Oersted Medal of the Association was presented to Prof. A. A. Knowlton, who responded by commenting on opportunities and rewards in physics teaching[1]; and the tenth Richtmyer Memorial Lecture was delivered by Prof. E. Fermi, who spoke on "Large-Cyclotron Research at the University of Chicago".

At the joint banquet in the evening the after-dinner speakers were Dr. O. E. Buckley, chairman of the board of the Bell Telephone Laboratories and of the Science Advisory Committee of the Office of Defense Mobilization, who described the relationship of the Advisory Committee with the government departments which it is designed to serve, and Prof. R. E. Peierls, of the University of Birmingham, who spoke about the status of physicists in Great Britain.

At the business meeting of the American Physical Society the following were elected to hold office for 1952: *President*, J. H. Van Vleck; *Vice-President*, E. Fermi; *Secretary*, K. K. Darrow; *Treasurer*, G. B. Pegram. The main business before the meeting was to consider urgently the extremely grave financial position of the Society. The treasurer reported that the surplus had been eaten away to such an extent that within a few months the Society would find it impossible to meet its commitments. This was due to the almost explosive expansion of the *Physical Review*, which again increased in 1951 by a thousand pages to a total of five thousand. The Council agreed to attack the problem not by limiting the size of the *Review* and thus excluding many worthy papers, but by increasing subscriptions, etc. The by-laws have been amended so that increased subscriptions may be obtained from members and fellows of the Society; at a recent meeting of the Council these have been fixed for 1953 at 20 and 30 dollars, respectively. The non-member subscription and the page charge for papers and letters in the *Review* have also been increased. An extra charge has been imposed on members who wish to subscribe to *Physics Abstracts*, and a registration fee for meetings has been imposed. The National Science Foundation has agreed to make a generous grant, and this will help to defray the deficits which the *Review* has incurred during 1951 and is bound to incur this year and next.

Twenty-seven invited papers were contributed at the scientific sessions held during the meeting of the American Physical Society. These included a special symposium of the Division of Electron Physics at which M. A. Biondi, P. Kusch and S. A. Korff spoke, respectively, on ionization and recombination processes in the afterglow, the magnetic moment of the electron, and recent developments in the physics of counters. In another session on electron physics, reports were given of the conference on gaseous electronics, held during October 1951, and of the National Bureau of Standards symposium on electron physics, held during November 1951. In the Division of Fluid Dynamics invited papers included one on flows in the vicinity of Mach No. 1 by a member of the Wright-Patterson Air Force Base. In nuclear physics there were contributions by K. T. Bainbridge and V. C. Weisskopf on nuclei, by members of Columbia University on pions, by J. H. Van Vleck on the significance of microwave spectroscopy for the theory of magnetism, and from Great Britain by R. E. Peierls and E. P. George, respectively, on non-local field theories and cosmic rays underground. Other branches of physics were also represented, with three papers on optical physics and others dealing with shock waves, high centrifugal fields and large molecules in biological systems. The complete list of papers, together with abstracts, is given in the minutes of the meeting[2].

The programme of the meeting of the Association of American Physics Teachers included a session of ten contributed papers and two invited addresses. A symposium of four papers by members of the Oak Ridge Institute of Nuclear Studies discussed various forms of nuclear reactors and accelerators. Another symposium was devoted to a discussion of methodology in the teaching of physics and included an address by J. B. Conant.

ACTION OF CARBOXYPEPTIDASE ON TOBACCO MOSAIC VIRUS

By Dr. J. IEUAN HARRIS and Dr. C. A. KNIGHT

Department of Biochemistry, University of California, Berkeley

THE chemical composition of tobacco mosaic virus has been investigated in considerable detail[1,2]. As a logical expansion of these and other studies, it becomes necessary to investigate the structural characteristics of the nucleic acid and protein moieties of the virus.

Several methods[3-6] are available for the identification of N-terminal groups in peptide and protein molecules, but no generally satisfactory method has been developed for the elucidation of corresponding C-terminal groups. The use of carboxypeptidase for the identification of the C-terminal residue of glutathione was reported by Grassman *et al.*[7], and Lens[8] has attempted to use the enzyme to determine the nature of the C-terminal groups of insulin. Results obtained from a study of the digestion of adrenocorticotropic hormone (ACTH) protein and peptide preparations by carboxypeptidase[9] led one of us[10] to re-investigate the potentialities of this reaction as a general method for the identification of C-terminal groups in polypeptide molecules. In this way the C-terminal groups of insulin, of fractions *A* and *B* derived from oxidized insulin, and of lysozyme were identified[10]; similar results for insulin have been reported by Sanger and Thompson[11], and for lysozyme by Thompson[12]. In the present investigation it has been found that threonine specifically is released by the action of carboxypeptidase on tobacco mosaic virus.

In preliminary experiments, an aqueous solution of a highly purified preparation of tobacco mosaic virus (containing 1·5 mgm. N/ml.) was incubated with carboxypeptidase (0·0028 mgm. enzyme N/ml.) at *p*H 7·0 and 25° for three hours. Enzyme action was terminated by spinning down the virus in the Spinco Model L ultracentrifuge. The presence of 0·8–1·0 per cent of non-protein nitrogen in the supernatant solution suggested that some proteolysis had occurred, and chromatography on paper led to the identification of threonine as the only product of the reaction (Fig. 1,*A*). No further reaction was found to occur when the treated virus was isolated and incubated with higher concentrations of enzyme for 24 hours (Fig. 1,*B*), and no ninhydrin-reacting substances were detected when control supernatant solutions from virus and enzyme, respectively, were chromatographed under the same conditions.

After it had been established that threonine was the only significant product of the action of carboxypeptidase on the virus, experiments were designed to investigate the nature of the reaction and to estimate the amount of threonine liberated. In a typical experiment, an aqueous solution of the virus (containing 1·4 mgm. virus N/ml.) was incubated with carboxypeptidase (0·0028 mgm. enzyme N/ml.) at *p*H 7·0 and 25°. Aliquots of the resulting solution were withdrawn at suitable intervals during a three-hour digestion period, and enzyme action was stopped by addition of 0·1 *N* hydrochloric acid to *p*H 3. After removal of the virus by ultracentrifugation, supernatant solutions were collected and their threonine content estimated by microbiological assay[1] at different dilutions. As shown in Fig. 2, liberation of threonine was essentially complete after 90 minutes and amounted to 74 μgm. threonine/9 mgm. of virus; this corresponds to approximately 7 per cent of the threonine content of the virus. In its initial stages the liberation of threonine appears to be a zero-order reaction with a *K* value of 2·0 (± 0·4) × 10^{-3} mgm./min.

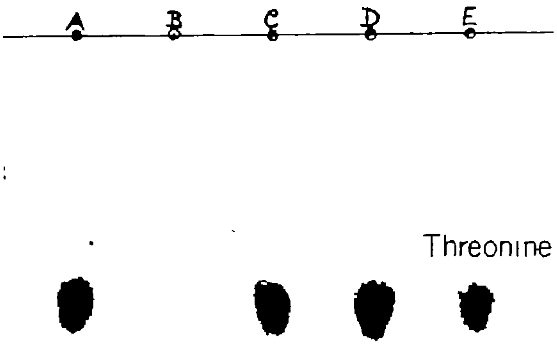

Fig. 1. Chromatography of supernatant solutions from carboxypeptidase-treated virus preparations (butanol/acetic acid/water, 4/1/5) *A*, tobacco mosaic virus-3; *B*, 'dethreoninized' tobacco mosaic virus-3, re-treated; *C*, control progeny; *D*, 'dethreoninized' progeny; *E*, threonine

The tobacco mosaic virus nucleoprotein appears to have a molecular weight of the order of 50,000,000[13]; on this basis it can be calculated that carboxypeptidase liberates more than 3,400 residues of threonine per mole of tobacco mosaic virus. The origin of this threonine is a matter of considerable interest. On the assumption that carboxypeptidase attacks only those peptide bonds adjacent to free α-COOH groups in polypeptide chains, it can be postulated that the protein moiety of the virus complex has more than 3,400 C-terminal threonine groups. As another possibility, one could envisage polythreonine components attached in some way to the virus molecule so that they are readily accessible for stepwise degradation by the enzyme. Several tobacco mosaic virus preparations, and a highly purified preparation of the Holmes's ribgrass (*HR*) strain, have

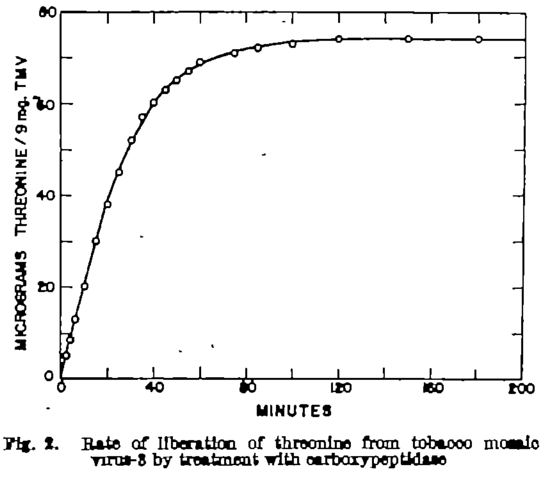

Fig. 2. Rate of liberation of threonine from tobacco mosaic virus-3 by treatment with carboxypeptidase

been found to yield similar amounts of threonine (see table) when treated with carboxypeptidase as described above. Other strains of tobacco mosaic virus and other viruses are currently under investigation. In this connexion, a preparation of tomato bushy stunt virus was examined and found to yield small quantities of several different amino-acids when treated with carboxypeptidase under conditions similar to those described for tobacco mosaic virus.

A tobacco mosaic virus preparation which had been treated with carboxypeptidase until liberation of its available threonine was complete was found to retain full virus infectivity when assayed by the half-leaf method. At the same virus concentrations, the control and 'dethreoninized' tobacco mosaic virus gave 21 and 20 lesions, respectively, as averages for twenty-nine half-leaves. In this respect, the virus resembles insulin and lysozyme, for it has been shown[14,15] that C-terminal alanine and C-terminal leucine, respectively, are apparently not essential for the biological activities of these proteins.

MAXIMUM YIELDS OF THREONINE OBTAINED FROM TOBACCO MOSAIC AND *HR* VIRUS PREPARATIONS BY REACTION WITH CARBOXYPEPTIDASE*

Virus preparations	μgm. Threonine per 10 mgm. virus
Tobacco mosaic virus-1	81
Tobacco mosaic virus-2	86
Tobacco mosaic virus-3†	82
Control tobacco mosaic virus progeny	93
'Dethreoninized' tobacco mosaic virus progeny	92
HR	88

* See text. † See Fig. 2.

It was of considerable interest to see whether the 'dethreoninized' virus represented a laboratory-produced mutant capable of reproduction in its modified form. To test this possibility, two sets of young, healthy tobacco plants were inoculated with high dilutions of 'dethreoninized' and control virus, respectively. The disease symptoms observed on the two sets of plants were indistinguishable, and, after sixteen days, highly purified preparations of virus were obtained from the plants in the usual manner. When these preparations were treated with carboxypeptidase, it was found that threonine was released from both samples (Fig. 1, *C* and *D*) and that it was released in equivalent amounts (see table). Thus it appears that about 7 per cent of the threonine of the virus can be removed without changing quantitatively or qualitatively the host–virus relationship.

This work is being extended and will be published in greater detail at a later date. We are grateful to Miss Theresa Litwin for the microbiological assay results and to Ning G. Pon for valuable technical assistance.

ISOLATION OF PORPHOBILINOGEN FROM THE URINE OF A PATIENT WITH ACUTE PORPHYRIA

By R. G. WESTALL

Medical Unit, University College Hospital Medical School, London, W.C.1

THERE is, in the urine of patients suffering from acute porphyria, a substance which gives a red colour with Ehrlich aldehyde reagent. This compound, porphobilinogen, is, so far as is known, only present in the urine of such cases and has, hitherto, never been isolated in the pure state. It has been the subject of study by several workers (Waldenström and Vahlquist[1], Prunty[2], Brockman and Gray[3], and Herbert[4]) since it was originally discovered by Sachs[5]. Waldenström and Vahlquist[1] suggested from diffusion measurements made upon partially purified porphobilinogen that it might be a dipyrrylmethane. They produced evidence that it was convertible under suitable conditions into a 'uro-type' porphyrin and/or porphobilin, a red pigment with urobilinoid characteristics. The view that porphobilinogen is a precursor of uroporphyrin has been generally accepted; but recently Hawkinson and Watson[6] have disputed this. In their view, uroporphyrin arises from an Ehrlich-negative substance.

All investigations, so far, have been carried out on porphobilinogen 'concentrates' of varying degrees of purity. Isolation of the crystalline substance has now provided the opportunity of making a further study of its properties.

Preliminary experiments showed that porphobilinogen was retained on a column containing the cation-exchange resin 'Zeo-Karb 215' and could be displaced by dilute ammonia. Similarly, it was held on the anion-exchange resin 'Dowex 2' and could be recovered with dilute acetic acid or ammonium acetate. By utilizing these resins and also acetic acid-treated alumina (Prunty[2]), concentration has been greatly facilitated, but recoveries have been low—partly due to instability of the compound in solution at room temperature and partly to a considerable loss, by degradation, on the 'Zeo-Karb 215' column. It has been found that porphobilinogen can be completely precipitated from urine by mercuric acetate and recovered without loss by treatment with hydrogen sulphide. Such concentrates are readily freed from accompanying bases and ampholytes by anion-exchange resin and alumina columns.

In a typical preparation, crystalline porphobilinogen has been obtained from the urine of a patient (I. McL.) with acute porphyria (admitted to the Metabolic Ward of University College Hospital under Dr. C. E. Dent and Dr. E. A. Blake Pritchard). 20 l. were adjusted to *p*H 4·5 with glacial acetic acid and shaken with 400 gm. of talc to remove preformed porphyrin. After filtration, warm, saturated, mercuric acetate solution was added in slight excess. The precipitate was washed twice with 1 per cent w/v mercuric acetate. The mother liquor and washings gave no red colour with Ehrlich's reagent (20 gm. *p*-dimethylaminobenzaldehyde in 500 ml. of 36 per cent w/v hydrochloric acid and 500 ml. of water). The precipitate, suspended in 2 l. of water, was saturated with hydrogen sulphide. The filtrate and washings from the sulphide were aerated and an assay carried out which showed that the solution contained 53·5 units/ml. (Vahlquist[7]) of porphobilinogen. The solution was then passed through a system of columns containing the prepared anion-exchange resin 'Dowex 2'. This set was made up of three glass tubes of decreasing size connected in series with narrow glass tubing (Westall[8]). When all the solution had passed on to the columns, water (500 ml.) was applied, and this was followed by 0·1 *M* ammonium acetate at a rate not exceeding 200 ml./hr. Under these conditions, the coloured substances, which had been carried down with the mercuric acetate precipitation, were firmly held by the resin, while the effluent containing porphobilinogen was practically colourless. This was collected in 50-ml. fractions which were assayed (Fig. 1). The total recovery was 86,000 units (80 per cent). Paper chromatography of the main fractions revealed the presence, besides porphobilinogen, of two unknown substances, one giving a bright blue and the other a green fluorescence in ultra-violet light.

The richest fractions were combined, and the porphobilinogen was again precipitated with mercuric acetate. After removing mercuric sulphide and hydrogen sulphide as before, the solution (300 ml.) was applied to an alumina column previously treated with acetic acid (Prunty[9]) and washed with water. The column (diameter 3·5 cm.) contained 80 gm. of alumina (Savory and Moore, Ltd.). A narrow dark band of porphobilin remained at the top of the column, and just below this a yellow band (the green fluorescent substance) was observed. The substance which gave the blue fluorescence in ultra-violet light passed quickly through in the effluent, and by following the original solution with several applications of water this substance was completely eluted before porphobilinogen was detected in the effluent. 0·1 *N* ammonia was run on to the column, and porphobilinogen was eluted, contaminated only with ammonia and ammonium acetate. On adjusting the solution to *p*H 4 with acetic acid, the free base crystallized immediately. After standing overnight at 0° C., the crystals, which were faintly pink in colour, were filtered, washed thoroughly with water and dried over phosphorus pentoxide. The first crop yielded 210 mgm., and a further crop of 90 mgm. was obtained by rechromatographing the tail fractions which were contaminated by material from the yellow band. The final yield was approximately 40 per cent of that calculated to be present in the original urine.

Properties of porphobilinogen. The pinkish-white crystals (Fig. 2) darkened on heating to 120–130° C. and decomposed with evolution of gas at 175–180° C. Microanalysis gave the following—found: C, 52·75; H, 6·80; N, 12·08 per cent; $C_{10}H_{16}N_2O_4$ requires C, 52·64; H, 7·02; N, 12·28 per cent. Approximately one-half (6·5 per cent) of the total nitrogen was liberated as nitrogen by nitrous acid in the Van Slyke apparatus, and a similar amount (5·9 per cent) was obtained as free ammonia on distillation in phosphate buffer (*p*H 8·5) at 100° C. No ammonia was obtained, however, when the distillation was carried out at 40° C.

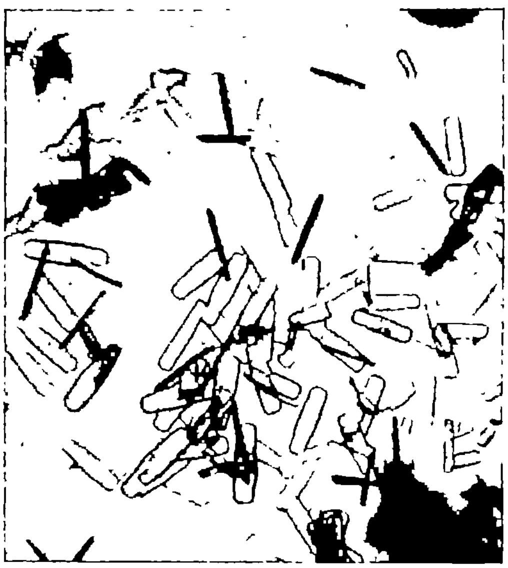

Fig. 2. Porphobilinogen crystals. × 480

Porphobilinogen crystals were almost insoluble in cold water and in the common organic solvents; they dissolved readily in dilute ammonia and could be recrystallized by bringing the solution to *p*H 4 with acetic acid. The use of sodium or potassium hydroxide instead of ammonia and subsequent neutralization with hydrochloric acid or acetic acid caused the solution to darken quite rapidly. Using Vahlquist's[7] technique and definition, the crystals were assayed at 130 units/mgm. On dry-heating a few crystals to 170° C. and dissolving the residue in dilute hydrochloric acid, the red fluorescence typical of porphyrins was observed under ultra-violet light, and paper-chromatographic analysis using lutidine (Nicholas and Rimington[8]) revealed a slow-moving spot due to 8-carboxyl porphyrin together with faster-moving weaker spots probably due to other partially decarboxylated porphyrins. Porphobilinogen formed a readily crystallizable hydrochloride which was soluble in water but less soluble in 2 *N* hydrochloric acid, m.p. 165–170° C. (decomp.).

Uroporphyrin formation from porphobilinogen. Solutions of porphobilinogen in inorganic buffers darkened on standing in the light at room temperature with the formation of a purplish-red pigment which, on reaching a critical solubility, formed a black deposit. This material gave the typical absorption band of porphobilin and a positive biuret but negative Ehrlich aldehyde test; there was no evidence of any trace of uroporphyrin. If, however, similar porphobilinogen solutions were boiled, with or without the presence of buffers at any *p*H between 1 and 8, a proportion of uroporphyrin was formed and was identified chromatographically as an 8-carboxyl porphyrin. Herbert[4] maintained that the maximum

5·5 *N*	17·1	8·5	9·4

uroporphyrin yield was obtained by boiling porphobilinogen solutions in the presence of 0·05–0·2 *N* hydrochloric acid and that the presence of buffer salts led to lower yields. This view has been confirmed in the present work, except that it would appear that slightly greater strength of hydrochloric acid (0·3–0·5 *N*) is required for optimum conversion to uroporphyrin (Table 1).

In an early experiment, using a 'Dowex 2' resin for separating porphobilinogen, a number of serial fractions containing this substance were assayed for the colour given by Ehrlich's reagent and also for the uroporphyrin developed by boiling with acetate buffer at *p*H 4·2 for twenty minutes (the optimum conditions were then unknown). These results, which are presented graphically in Fig. 3, indicated that a constant ratio existed between the Ehrlich colour and the uroporphyrin yield throughout the fractionation. If some substance other than porphobilinogen was yielding uroporphyrin, some variation, however slight, of this ratio would have been expected.

Paper chromatography of porphobilinogen. Porphobilinogen can be detected on paper chromatograms (Consden, Gordon and Martin[10]) in amounts as small as 0·25 μgm. by spraying with Ehrlich's reagent. By this means it has been possible to assess the purity of the various fractions obtained during the isolation procedures. It is also possible to demonstrate the formation of uroporphyrin from porphobilinogen by heating the paper strips for fifteen minutes at 100° C. in a vessel containing acetic acid vapour and then viewing under ultra-violet light. This test, however, is not as sensitive as the Ehrlich reagent, and it is necessary to use 3–4 μgm. of porphobilinogen. A number of fractions containing porphobilinogen and also solutions of the pure substance have been run on duplicate paper strips using different solvent mixtures. After drying, one strip was sprayed with Ehrlich reagent, while the other was heated for uroporphyrin development. In all, six different solvent mixtures have been used, and in every case the position (R_F value) of the Ehrlich-reacting spot has coincided with the position of the uroporphyrin (Table 2).

Discussion. While the results recorded above concerning the elementary composition of porphobilinogen, its basic properties, reaction with nitrous acid and its conversion to uroporphyrin, etc., when taken in conjunction with established facts concerning the biosynthesis of protoporphyrin, obviously suggest certain structural possibilities, it is felt that any present discussion of these would be premature. Porphobilinogen, the excretion of which represents the main apparent metabolic error of the acute porphyria patient, is not necessarily a normal step in the biosynthesis of uroporphyrin, and *in vitro* yields of uroporphyrin from it have not, so far, exceeded 40 per cent; moreover, some conversion also occurs, under the same conditions, to porphobilin, a pigment having urobilinoid rather than porphyrin characteristics.

A molecular weight cannot yet be assigned to porphobilinogen, so the question of its pyrrolic or dipyrrylmethane character must remain open. The substance is unstable, and experimental work with it presents many difficulties. The investigation is proceeding along both chemical and pharmacological lines in collaboration with Prof. C. Rimington and Dr. W. D. M. Paton, and a full account will be published in due course.

I wish to thank Prof. C. Rimington for advice and encouragement and for carrying out the Ehrlich and uroporphyrin assays. I am also indebted to Mr. J. Smiles and Mr. J. Harmer, of the Optical Department of the National Institute for Medical Research, for the photograph of crystalline porphobilinogen. The microanalyses were made by Mr. F. H. Oliver, of the Microanalytical Laboratory of the Organic Chemistry Department, Imperial College of Science and Technology, London.

Motor End-Plate Differences as a Determining Factor in the Mode of Action of Neuro-Muscular Blocking Substances

In consequence of the results obtained with decamethonium in the cat[1,2] and in human beings[3], we felt justified in putting forward the thesis that decamethonium produced a neuromuscular block in mammals only through a persisting depolarization of the motor end-plate. But work undertaken with other mammalian species (monkeys, dogs, hares) during the past few months reveals that decamethonium can produce in these three a neuromuscular block which differs in many ways from the block produced by pure depolarization. Thus in these species the tetanus is poorly sustained, and antagonizes the block, which is also antagonized by anticholinesterases. The white muscles show an acute decreasing sensitivity to decamethonium, a second injection of a dose which at first produced almost complete paralysis failing to produce any effect. If one records simultaneously from a red muscle and a white one[4], a transition from a depolarizing type of block to a block by competitive inhibition is seen.

Succinylcholine, a pure depolarizing substance, when used on the cat, gave similar results to decamethonium on the monkey and the dog. These findings clearly indicate that decamethonium and succinylcholine can no longer be described as purely depolarizing substances in these species. What, then, are they ? Undoubtedly they are not just competitive inhibitors, because in the first place they produce features of a depolarizing substance, and in the second place the muscles of the species under consideration show an acute decreasing sensitivity to decamethonium and to succinylcholine. Such a result is never obtained from a competitive inhibitor like *d*-tubocurarine. The impression resulting from the study of these facts is that the picture obtained in the monkey and the dog is similar to that obtained in the cat when an injection of *d*-tubocurarine is interposed between the first and subsequent doses of decamethonium.

A tentative suggestion I should like to put forward is that there may be a dual mode of action of decamethonium and succinylcholine upon the muscles of these animals. It seems possible that, while the molecules at first adhere in the specific way necessary to produce a depolarization at the end-plate, their grip eventually changes, with the result that from depolarizing substances they become competitive inhibitors.

This idea is strengthened by two other observations. A higher member of the same series as decamethonium, tridecamethonium, produces in the cat a similar picture to that produced by decamethonium in the monkey and in the dog. This shows that if the polymethylene chain is lengthened, the molecule loses the specific property required to produce a neuromuscular block by pure depolarization even in the cat. The other observation relates to the action of these substances on avian muscle[5]. In birds, *d*-tubocurarine produces the usual paralysis, whereas decamethonium and succinylcholine produce a pure contracture characterized by extension of the limbs and retraction of the head[5]. If the dose is small, recovery is abrupt ; if large, the animal dies in contracture and never exhibits paralysis. But when an injection of tridecamethonium is given, a completely different picture is produced. First contracture appears ; but slowly, while the legs are still extended, the head drops forward in paralysis and finally the paralysis extends to involve the muscles of the leg so that the whole animal becomes flaccid. In the bird, as in the monkey, we start with a decamethonium picture and finish with a *d*-tubocurarine one.

Hitherto it has generally been assumed that results obtained from experiments upon one mammal could safely be regarded as typical for mammals in general. It is now clear that results obtained from the muscle of any one mammalian species are valid only for this species, and perhaps for the particular muscle upon which the experiment was made.

These findings seem to provide an explanation for the varying sensitivity of different species to decamethonium. In species where depolarization is the only mode of action of decamethonium, sensitivity is great. But immediately the dual mode of action comes into play, the muscle becomes more resistant to decamethonium, most probably because these two modes of action are antagonistic.

The variations of the cat, monkey and dog muscles in response to substances like decamethonium and succinylcholine show that there must be distinct physical differences between the muscle membranes of these mammalian species, in spite of the similarity of their reaction to acetylcholine— a fact revealed so far only by such pharmacological analyses. These normally occurring differences in certain species may appear as pathological changes in the muscles of any one species. Taking into consideration results obtained by Churchill-Davidson and Richardson (see succeeding communication), we may reasonably conclude that the myasthenic syndrome is due to changes developing at the motor end-plates of these subjects ; these changes make them react to their own acetylcholine as if acetylcholine were a competitive blocking substance.

[5] Buttle, G. A. H., and Zaimis, E. J., *J. Pharm. Pharmacol*, 1, 991 (1949)

The exact mechanism responsible for the muscle weakness and rapid fatigue characteristic of myasthenia gravis remains unknown, although it has long been recognized to be associated with a failure of neuromuscular transmission. Three main factors have been suggested as the possible cause of this neuromuscular block: first, a reduction in the amount of acetylcholine liberated at the myoneural junction ; secondly, an excessive rate of its destruction due to increased esterase activity; and thirdly, the prevention of its depolarizing action on the motor end-plate by a curare-like substance.

There is no adequate evidence to indicate an abnormality in the production or destruction of acetylcholine in myasthenia, and one could not explain on such a basis the properties of the neuromuscular block found in this condition. This block exhibits the properties of one due to competitive inhibition in that it is greater at high rates of neuromuscular stimulation and reversed by substances having only an antagonism for competitive block in common; for example, neostigmine, tetraethylpyrophosphate, adrenaline and potassium salts. Direct evidence for the presence of a curare-like substance is based on the claim of Wilson and Stoner[1] to have detected it in blood samples obtained from myasthenic patients. Their claim, however, remains unconfirmed.

Recent investigations into the action of decamethonium salts on voluntary muscles indicate that another mechanism must be considered as a factor in this abnormal neuromuscular transmission of myasthenics. In normal human muscles decamethonium (*C*.10) has been shown to produce neuromuscular block by depolarization[2], such as it does in certain other species; for example, the cat[3,4]. Electromyographic recordings taken from normal human muscles show that the characteristic features of such a decamethonium block are that it is potentiated by anti-cholinesterase substances; twitch and tetanus are equally well sustained; a steady but progressive fall in the height of the action potential follows the administration of the drug, and finally, muscle twitches and tightness are a marked feature, especially in the jaw and calf muscles.

The muscles of myasthenic patients, however, show a very different response. We have previously demonstrated that they exhibit a diminished sensitivity to the neuromuscular blocking action of decamethonium which is most marked in those muscles showing little clinical weakness[5]. We have now carried out further investigations into the neuromuscular block that can be induced in the clinically weak muscles of myasthenic patients by decamethonium and have observed that it differs radically from that induced in the muscles of normal subjects under identical conditions. The block in myasthenic muscle is rapidly and completely reversed by anti-cholinesterase substances; tetanic rates of stimulation are not so well sustained as twitch; there is often a marked and prolonged rise in the height of the action potential following decamethonium, and muscle twitching and tightness are absent in this group of subjects. These changes in the mode of response of myasthenic muscle to decamethonium can only be explained by the production of a neuromuscular block due to competitive inhibition by this compound. They are in contrast to the depolarizing block induced by decamethonium in normal subjects.

The conception of decamethonium acting as a competitive inhibitor in myasthenia could be accounted for in two ways: first, by an alteration in the composition of the drug, and secondly by a change in the mode of response of the receptor—the motor end-plate. Biological assays of the urine of our myasthenic patients and normal control subjects show that in both groups the decamethonium is excreted at identical rates and unchanged. It must be concluded, therefore, that in cases of myasthenia gravis the affinity of the motor end-plate for decamethonium changes, so that its threshold is raised for this compound and a block characteristic of competitive inhibition results.

A dual mode of action of decamethonium is suggested by Zaimis in the preceding communication. Her observation that tridecamethonium, decamethonium and succinylcholine exhibit this dual action in different species and, indeed, in different muscles of the same species, leads us to suggest that acetylcholine—a depolarizing substance for all normal muscle—may under certain conditions exhibit this dual mode of action. When it does so in the human species, the result is the weakness and fatigue characteristic of myasthenia gravis.

We believe that the production of competitive inhibition of neuromuscular transmission by decamethonium and acetylcholine in myasthenia can result from changes in the motor end-plates. This hypothesis would explain our results and all the features of the disease, including notably the involvement of isolated muscles.

An Antifungal Polypeptide produced by *Bacillus subtilis*

DURING work on cultures of *Penicillium roqueforti*, a contaminant was isolated which caused pronounced inhibition of the growth of that mould. The contaminant, when purified and characterized according to Bergey[1], proved to be *Bacillus subtilis*.

The isolate, when grown in shallow broth cultures on the medium used in the production of mycosubtilin[2], produced active solutions. Activity was determined according to the procedure described by Turner-Graff[3], with *P. roqueforti* as test organism. The optimum temperature was 25°–30° C., and maximum yield was obtained in four to six days. The cell-free fluid was active up to a 1 : 10 dilution.

The following procedure was developed for the preparation of the inhibitor. The cell-free fluid from cultures grown as described above was extracted with half its volume of *n*-butanol. The butanol layer was separated and vacuum-distilled at 60°–70° C. A viscous brown residue was obtained which was taken up in water and treated with hydrochloric acid until there was no further precipitation. The precipitate was separated and dissolved in a minimum amount of sodium hydroxide. The solution was diluted with water and reprecipitated with hydrochloric acid. The precipitate was rinsed with water and dissolved in a small volume of ethanol. The solution was then treated with an excess of ethyl ether, and a voluminous white-to-brown precipitate was obtained. Further purification was accomplished by repetition of the above alcohol–ether procedure. The ether precipitate was filtered and dried at 105° C. to a yellow-brown substance.

The inhibitor proved to be a non-dialysable heat-stable polypeptide. It gave positive biuret and xanthoproteic reactions. The Molisch test was negative. The nitrogen content of the dried product was 11–11·5 per cent.

A single counter-current distribution run with 25 tubes, in the system *M*/10 phosphate buffer *p*H 8·7 and *n*-butanol, indicated that the peptide was homogeneous. It is an acid polypeptide with a *p*K of about 5·5 and an equivalent weight of approximately 1,000 when titrated with sodium hydroxide. The polypeptide is insoluble in distilled water, soluble above *p*H 6. It dissolves without difficulty in methanol, ethanol and *n*-butanol.

Paper-partition chromatography of an acid hydrolysate with a phenol – water system using the capillary ascent method of Williams and Kirby[4] showed the presence of seven amino-acids. Glutamic acid predominated. The other amino-acids identified were aspartic acid, serine, alanine, valine, leucine and phenylalanine.

The antibiotic spectrum of this compound is now being investigated. Results obtained so far indicate that it is active against *Penicillium roqueforti* at concentrations of 0·05–0·1 mgm./ml., and against *Aspergillus niger* at 0·2 mgm./ml. At these concentrations, there was no effect on *Staphylococcus aureus*, *Klebsiella pneumoniæ*, *Escherichia coli*, *Streptococcus fæcalis* and *Streptococcus lactis*.

The inhibitor is therefore mainly antifungal. A comparison of its properties with those of the other two known antifungal polypeptides produced by *B. subtilis*, mycosubtilin[2] and fungistatin[5], shows it to be different.

A more detailed report of this work will be published elsewhere.

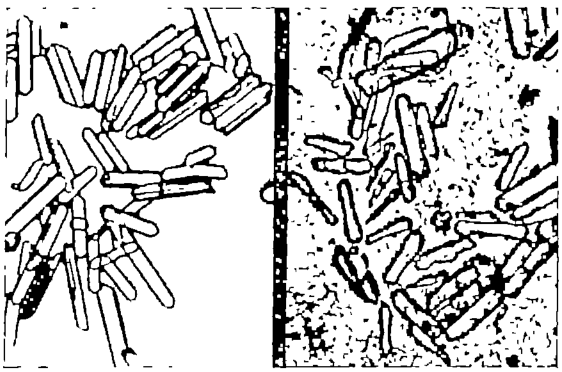
Lipoid Solubility as a Factor in the Toxicity of Contact Insecticides

Contact insecticides as a class are lipoid-soluble, and it is reasonable to surmise that the first step in their uptake or pick-up by the insect might be generally their dissolution in the epicuticular waxes. All the same, experimental evidence of this phenomenon does not seem to exist, and relative solubility of insecticidal chemicals in cuticular waxes of insects has not been studied so far as known to us. Recently, it has been possible to develop a fairly handy technique for such studies and to collect thereby some experimental evidence of the existence of correlation between lipoid solubility and insecticidal action.

Lipoid solubility. Cuticular waxes were extracted from the larval exuviæ of two species of insects, namely, *Euproctis lunata* Wlk. (Lymantridæ, Lepidoptera) and *Trogoderma granaria* Everts. (Dermestidæ, Coleoptera), which had been found in earlier experiments to show very wide differences in their susceptibility to suspensions of DDT crystals. The extract from *E. lunata* formed 2·95 per cent of dry weight of the exuviæ and was a grease-like wax with a deep yellowish-green colour and a melting point range of 47–54° C. That from *T. granaria* formed 3·93 per cent of the dry weight of the exuviæ and was hard brittle wax, light yellow in colour and with a melting point range of 77–83° C. Both were readily soluble in cold chloroform, benzene and xylol, and were sparingly soluble in alcohol and acetone. In order to study the solubility of DDT in these extracts. they were dissolved separately in chloroform, giving a 0·05 per cent separate solution of each. Then 1 c.c. of this solution was spread uniformly on a glass cover slip (2·25 cm. square) and the chloroform allowed to evaporate, leaving a more-or-less uniform wax film on the cover slip. Taking the relative density of insect waxes as 0·96 gm./c.c.[1], the approximate thickness of this wax film was about 10 µ. The films thus made from the two cuticular extracts were uniformly sprayed under a spraying tower with a suspension of DDT crystals (8 × 32 µ in size), in acetone – water medium, and examined under the microscope. Particular areas on the film were marked out, and the fate of the DDT crystals in those areas observed at very short intervals. It was observed that: (*a*) as soon as the crystals settled on the wax films they started sinking into the wax; this process was very rapid in the case of *Euproctis* wax, the crystals being completely covered by wax in about one minute, whereas the same process took 15–30 minutes in the case of *Trogoderma* wax; (*b*) DDT crystals started showing signs of dissolution (see accompanying illustration) within five minutes and completely disappeared in 30–45 min. on *Euproctis* wax, whereas very few crystals showed any sign of dissolution on *Trogoderma* wax during the corresponding period; (*c*) a few crystals which were left undissolved on *Euproctis* wax were found on close examination to be enveloped in a film of water which obviously hindered their dissolution. No such reason could be adduced for DDT crystals not dissolving on *Trogoderma* wax.



(*a*) (*b*)

DDT crystals: (*a*) on glass slide, and (*b*) on film of *Euproctis* wax showing signs of dissolution in losing their shape, and dwindling in size. The respective enlargements of (*a*) and (*b*) are not the same

Relative susceptibility. Correlated with the difference in the relative solubility of DDT in the cuticular extracts of the two species, there was a great difference in their relative susceptibility to suspensions of DDT crystals as shown in the accompanying table.

When sprayed grubs of the resistant species *T. granaria* were observed under the high power of a binocular microscope, the DDT crystals could be easily detected even after a week with their outline more or less intact on the insect body, indicating that the DDT crystals were not being absorbed quickly.

TOXICITY OF DDT CRYSTALS TO *E. lunata* AND *T. granaria* LARVÆ UNDER ALMOST IDENTICAL CONDITIONS

% concentrations	Mortality % in *E. lunata* 4 days after spraying				Mortality % in *T. granaria* 50 days after spraying			
	S	*M*	*B*	*C*	*S*	*M*	*B*	*C*
0·125	80	80	64	73	26	22	28	30
0·0625	62	64	44	56	20	18	8	14
0·03125	44	44	31	38	4	8	2	6
0·0156	31	33	24	27	0	2	0	2
Control	4				0			

S, DDT crystals 2 × 10–12 μ in size; *M*, the same, 4 × 12–16 μ; *B*, same, 8 × 30–32 μ; *C*, same, of nearly colloidal dimension.

Effect of temperature. This film technique also made it possible to have some idea about the effect of temperature on the solubility of DDT crystals in these waxes. Films with DDT crystals on them were kept at 32° C. and in a refrigerator (10–15° C.). It was found in the case of *Euproctis* wax that all the crystals were dissolved within one hour at 32° C., but only a very small number did so even in 24 hours at 10–15° C. The crystals on *Trogoderma* wax showed only slight change at both these temperatures.

Oxidative Degradation of Testosterone by Adaptive Enzymes

THE study of steroid synthesis by micro-organisms and certain oxidations and reductions of reactive groups at positions 3 and 17 of the steroid skeleton have been previously reported[1]. Turfitt[2] has studied more extensive degradations of cholesterol by bacteria and has isolated products in which the side-chain has been removed and ring *A* opened. We should like to report the application of adaptive bacterial enzymes to the study of the oxidative degradation of steroid hormones.

An unidentified, Gram-negative, flagellated bacillus (probably a non-fluorescent *Pseudomonas*), which can utilize testosterone as its sole source of carbon, has been isolated from the soil by enrichment cultures. Colonies growing on agar plates in which testosterone has been finely dispersed produce extensive zones of 'clearing' at some distance from their margins (Fig. 1). When testosterone is the only source of organic carbon in the medium, relatively poor growth of this micro-organism is obtained. We have grown cells as a routine in well-aerated liquid cultures at 30° C. in a medium containing 2·5 mgm. per ml. of finely dispersed testosterone and 2·5 mgm. per ml. water-soluble yeast-extract, in addition to ammonium sulphate and requisite mineral salts (magnesium sulphate, sodium chloride and potassium mono- and di-hydrogen phosphate). Washed cell suspensions of organisms grown in this manner carry out vigorous and extensive oxidations of testosterone. These oxidations may be conveniently studied manometrically with 1–2 μ*M* of steroid suspended in 0·03 *M* phosphate buffer *p*H 7·2 at 30° C. in air. Under such conditions, the activity of oxidation may vary in different preparations from $Q = 60$–200 μl. oxygen/mgm. dry weight/hr., whereas the endogenous respiration amounts to 20–25 per cent of this. The total oxygen consumption is proportional to the quantity of testosterone added, and usually amounts to 40–60 per cent of the theoretical amount for complete oxidation to carbon dioxide and water. In the presence of critical concentrations of 2,4-dinitrophenol, the total oxygen consumption may approximate to the theoretical for complete oxidation.

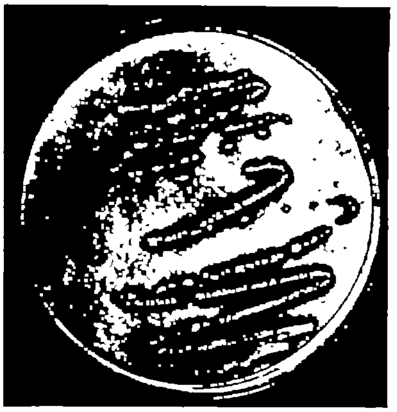

Fig. 1. Colonies growing on agar containing finely dispersed testosterone, ammonium sulphate and mineral salts

The enzymes involved in these oxidations are adaptive, as the organism grown on yeast extract alone will not immediately oxidize testosterone. Washed cells grown on yeast extract, when placed in Warburg vessels in phosphate buffer at *p*H 7·2 and 30° C. in air, will, in the absence of an exogenous nitrogen source, become adapted to oxidize testosterone after a lag period of 8–10 hr. The specific activities obtained during *in vitro* adaptation are considerably lower ($Q = 5$–10 μl. oxygen/mgm. dry weight/hr.) than those achieved by growing the organism in the presence of the steroid.

Testosterone-adapted cells will also vigorously oxidize a series of related 19-carbon steroids, such as androst-4-ene-3,17-dione, androstane-3,17-dione, 17-epitestosterone, dehydroepiandrosterone, epiandrosterone, and dehydroandrosterone. The presence of a side-chain at carbon 17, for example, methyltestosterone, precludes oxidation. Natural œstrogens, such as œstrone and œstradiol, as well as synthetic œstrogens, such as *bis*dehydrodoisynolic acid methyl ether and diethylstilbœstrol, are not attacked by this micro-organism. Adrenal cortical steroids (compound *E*, compound *F* and deoxycorticosterone) are likewise resistant to oxidation.

The terminal oxidative pathway appears to be by way of the tricarboxylic acid cycle, as the oxidation of testosterone is inhibited by tricarboxylic acid enzyme inhibitors (malonate and fluoroacetate), and certain of the cycle enzymes (*iso*citric dehydrogenase and fumarase) have been demonstrated in cell-free extracts of the organism.

Cell-free extracts prepared from washed testosterone-adapted cells by grinding with alumina[3] will carry out the initial oxidation step of testosterone, whereas extracts of unadapted cells grown on yeast fail to do so. The adapted extracts contain a diphosphopyridine nucleotide-specific enzyme which will oxidize testosterone and dehydroepiandrosterone. This enzyme is distinct from ethanol dehydrogenase. The steroid oxidations can be studied spectrophotometrically by measuring the appearance of

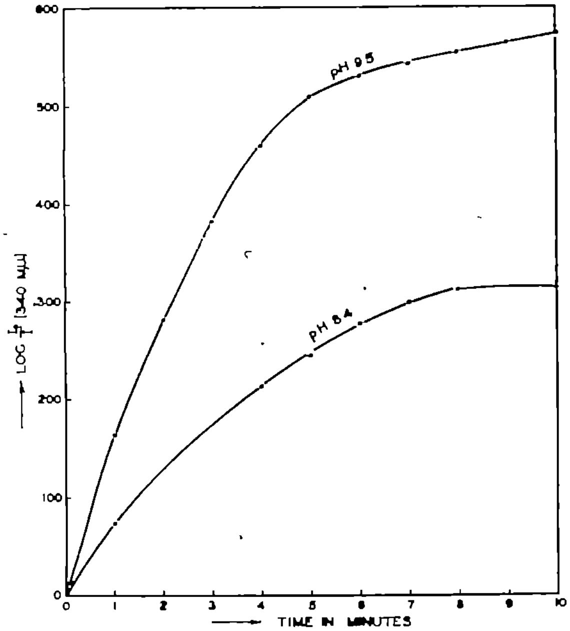

Fig. 2. Reduction of diphosphopyridine nucleotide by enzyme extract of testosterone-adapted cells in presence of testosterone at 25° C. and pH 8 4 and 9·5. Optical density readings at 340 mμ, corrected for endogenous reduction of the nucleotide (c. 15 per cent of total). System: Phosphate buffer 0·03 *M*, 0 05 ml. enzyme, 0·1 ml. diphosphopyridine nucleotide (0 34 μ*M*), 2·0 ml. aqueous testosterone (0·1 μ*M*). Total volume 3 ml. Reaction started by adding the nucleotide

reduced diphosphopyridine nucleotide at 340 mμ (Fig. 2).

The rate and equilibrium are markedly sensitive to *p*H, the rate being greater at *p*H 9·5 than at lower *p*H, and the equilibrium shifts in favour of the complete oxidation of testosterone as the *p*H of the reaction medium increases. The product of testosterone oxidation has been isolated by paper chromatography (using formamide-impregnated paper and a moving phase consisting of a mixture of equal parts of hexane and benzene) and behaves chromatographically like androst-4-ene-3,17-dione.

A few micrograms of testosterone can be detected by measuring the reduction of diphosphopyridine nucleotide with the aid of this enzyme extract, and fractionation of the latter is being undertaken in the hope of developing a sensitive, specific assay for testosterone and related steroids. Full experimental details will be given in a future publication.

This work was supported by grants from the American Cancer Society, recommended by the National Research Council Committee on Growth and the Jane Coffin Childs Memorial Fund for Medical Research. We are indebted to Chemical Specialties, Inc., New York, and Schering Corporation, Bloomfield, New Jersey, for generous gifts of a variety of steroids.

Enzymes of *Vibrio choleræ*

BURNET'S discovery[1] of an epithelium-desquamating enzyme in *V. choleræ* filtrates has opened up a new line of approach in the investigation of the pathogenesis of cholera.

Using pure collagen prepared by the method of Highberger[2] from buffalo tendo Achillis, we have been able to demonstrate, in culture filtrates of *V. choleræ*, a collagenase with an optimum *p*H of 8·0. This enzyme could not be detected in culture filtrates of *B. coli*. The method employed for this study was as follows. 4-ml. quantities of a Seitz filtrate of an 18–20-hr. culture in 1 per cent nutrient agar of *V. choleræ* (Inaba), after being adjusted to *p*H's ranging from 4 to 9 and made up to the same total volume of 6·4 ml. with distilled water, were treated with 0·2 gm. each of the collagen preparation and incubated for 48 hr. at 37° C. A boiled cholera filtrate – collagen control was also run in parallel. At the end of the incubation period, the undigested collagen was separated off and samples from the clear solution were taken out in duplicate for nitrogen analysis by micro-Kjeldahl method. The average nitrogen content in mgm. per ml. of the solution of closely agreeing duplicates is given in the accompanying table.

Nature of filtrate	*p*H	Nitrogen per ml of supernatant	Increase in nitrogen/ml of fresh filtrate incubates over control
V. choleræ, type Inaba	4 0	0 66	0·0
	5 0	0 814	0·154
	6 0	0·941	0 281
	7 0	0·947	0 287
	8 0	0·961	0·301
	9 0	0·918	0 258
Boiled *V. choleræ* filtrate (control)	6 0	0 66	
B. coli filtrate	7·0	0 972	0·013
	8 0	0 995	−0 015
Boiled *B. coli* filtrate (control)	7·0	0 959	
	8·0	1 01	

The increase in the dissolved nitrogen of the collagen–cholera-filtrate incubates over that of the control, with a maximum at *p*H 8·0, shows the presence of a collagenase in *V. choleræ*. This enzyme is capable of acting over a wide range, optimum effect being at *p*H 8·0.

Further work on vibrio enzymes is in progress. The evidence collected so far shows that collagenase is also present to some extent in culture filtrates of vibrios of non-choleragenic origin. Details of these investigations will be published shortly.

Chromatographic Isolation and Estimation of the Natural Œstrogens from Tissue

THE separate isolation and estimation of the three œstrogens in tissue at present entails the use of a large amount of material, with a separation by partition in solvents which is by no means perfect. The resulting product is very impure and has to be assayed biologically rather than chemically. Various chromatographic and other techniques have been tried to find a method of purification and separation[1-3], all of which for various reasons were found to be unsatisfactory for tissue extracts.

To avoid streaking, and to give reproducible R_F values for the œstrogens when run on paper chromatograms in the presence of the large amount of greasy impurity found in tissue extracts, it has been found essential to use an elevated temperature under the carefully controlled conditions recently described by Bush[4] for adrenal steroids. On this basis, and utilizing a new spotting technique, a method has been evolved for complete isolation and estimation.

Fresh human placenta has been used for these experiments, and extracts of up to 200 gm. were taken for a single run. The tissue was minced and extracted in a Soxhlet apparatus with methanol, which was removed *in vacuo*; the remaining sludge was extracted with ether. Where a hydrolysate was required, this was obtained by refluxing with 1·5 *N* hydrochloric acid and subsequent extraction with ether. The ether was washed with 9 per cent sodium bicarbonate, removed *in vacuo*, and the residue taken up in benzene. At this stage œstriol was separated from œstrone and œstradiol by thorough extraction of the benzene with water. The water was extracted with ether, and one volume of carbon tetrachloride added to 18 volumes of ether, which was then extracted with *N* sodium hydroxide. The sodium hydroxide was brought to *p*H 9 with sulphuric acid[2] and extracted with ether, which was evaporated to give the œstriol fraction. The œstrone and œstradiol fraction was obtained by extraction of the benzene with *N* sodium hydroxide and subsequent treatment as for the œstriol fraction.

The final extracts dissolved in ethanol were placed on strips, 5 in. by 18 in., of Whatman 541 filter paper, the ethanol being evaporated by a stream of air directed under the paper. (For quantitative work the paper must be extracted with methanol in a Soxhlet apparatus for several hours to remove impurities soluble in methanol.) The chromatograms were run overnight (16 hr.) by the descending technique in glass tanks in a uniformly heated cabinet containing an efficient fan, at 32° ± 0·5° C. The precautions described by Bush[4] regarding saturation of the atmosphere in the tanks must be taken. Equilibration is complete after 1–1¼ hr.

The mobile phase for œstrone and œstradiol was made from 1,000 ml. petrol ether (b.p. 100–120° C.), the stationary phase being methanol (1,000 ml.). For œstriol these were, respectively, benzene (1,000 ml.) and a mixture of methanol (500 ml.) with water (500 ml.).

The œstrogens were shown up as blue spots (minimum detectable, 0·5 μgm./sq.cm.) by spraying the paper with Folin and Ciocalteu's reagent[5] freshly diluted with five volumes of water, and hanging in a tank, the bottom of which was covered with 0·88 ammonia solution, until the spots reached maximum intensity (about 5 min.). The papers were dried at room temperature to give permanently stable chromatograms.

The œstrogens in the tissue extract are shown as sharply defined spots with no streaking after a 16-hr. run. The spots are well distributed over the paper, and the R_F values in the respective systems are œstrone 0·2, œstradiol 0·07 and œstriol 0·13.

Quantitative removal of the œstrogens from the paper was achieved by hanging the paper containing the spot at the base of a condenser, and refluxing with methanol for 15 min. In this case, the spots have to be found by running the extracts parallel with pure standards, and spraying only the standard strips so formed. The identity of the substances removed was proved by measuring their absorption spectrum, coupling with azo dye[1] and bio-assay. The amounts of œstrogens present have been determined by fluorimetry, bio-assay and absorption spectrophotometry, with good correlation of results. From 100 gm. of hydrolysed placental tissue, 3 μgm. œstrone, 1 μgm. œstradiol and 10 μgm. œstriol were obtained. Provisional recovery experiments, excluding the action of the hydrolysis, give results for the respective œstrogens of 80, 40 and 60 per cent. Most of this loss may probably be accounted for by trouble with emulsions, and fatty impurities disturbing the distribution coefficients. This is being investigated.

These figures agree with those obtained by Huffman *et al.*[6], who worked with more than 400 kgm. of placenta. The small amount of material required for the above method (minimum 50 gm.), and the comparatively short time taken for complete purification and chemical estimation, should now facilitate work in the field of œstrogen metabolism.

I would like to thank Dr. R. E. Davies for his help, also Prof. H. A. Krebs and Dr. C. G. Paine for interest and encouragement.

Transplantation of Mouse Sarcoma with Small Numbers of Single Cells

Although transplantation of leukæmia has been secured by the intravenous inoculation of a single leukæmic cell[1], transplantation of a solid tumour by a single malignant cell has not, so far as is known, been demonstrated. The fact that a leukæmic cell can normally exist as an isolated viable cell in a fluid environment is a special feature which has left open the possibility that single cells of a solid tumour may not so well survive the manipulations required for transplantation.

Single-cell suspensions of a spindle-cell sarcoma which arose in this laboratory in a transplantable mammary carcinoma of *C3H* mice have been prepared by prolonged sedimentation under gravity of tumour mince suspended in Tyrode solution containing 0·5 per cent gelatine. It has been found that between 80 and 90 per cent of the cells in such suspensions can be presumed to be non-viable, as indicated by diffusion of trypan blue into the nuclei[2] and by other evidence of degeneration apparent in phase-contrast microscopy. In recording the cell density of a suspension, therefore, account is taken only of the cells of which the nuclei fail to take up dye in the presence of 0·2 per cent trypan blue. 0·1-ml. volumes of serial dilutions of a single-cell suspension were inoculated subcutaneously into *C3H*

Dilution factor	Calculated number of cells in inoculum	Number of inoculations	Number of tumours	Positive inocula (per cent)
100	1,200	12	10	83
300	400	12	10	83
900	133	12	10	83
2,700	44	12	7	58
8,100	15	12	4	33
24,300	5	12	4	33

mice of between two and four months of age. The accompanying table shows the percentage of inocula, containing various numbers of viable cells, which gave rise to progressively growing tumours within the 40-day period of observation. The cell numbers given in the table are calculated from the viable cell density in the original suspension and the dilution factor.

From the table it will be seen that tumours arose from one-third of the inocula containing a calculated number of five cells. When the percentage of tumours arising from the various cell doses is calculated from the accumulated results according to the method of Reed and Muench[3], and plotted against the logarithm of the numbers of cells in the inocula, a sigmoid curve is obtained which approaches zero for both ordinate and abscissa. The number of cells required to give 50 per cent of positive inocula, read from the graph, is 14.

The technical error most likely to result in gross under-estimation of the number of cells in the most dilute inocula is contamination by cell clumps. This possibility is considered to be ruled out by the observations that (1) the viable cells showed no tendency to clump even in the most dense suspensions, and (2) no cell clumps could be seen in a volume of the undiluted suspension which contained 12,000 viable single cells. Other technical considerations, such as the possibility that a proportion of the cells not taking up trypan blue may nevertheless not be viable, and that some cells may be lost or damaged in the course of inoculation, make it probable that less than five cells was in some cases responsible for starting a fresh tumour. Since the volume of the inocula was 0·1 ml., it must be presumed that the single cells in the most dilute inocula were deposited in the tissues at some distance from one another. Assuming that such cells have no influence on one another, it must be concluded that fresh tumours arose from single isolated cells.

The necessity of absolute criteria for the exclusion of cells from the inoculum in experiments intended to demonstrate cell-free transmission of tumours is made clear when it is realized that, as implied by the results here reported, a tumour can result from the inoculation of 10^{-4} c.mm. of tumour tissue.

Similar experiments to the above have shown that about 2,000 viable cells of sarcoma 37 are required to give 50 per cent of positive inocula in a colony of mice uniformly susceptible to massive grafts. No successful transplantations have resulted from the inoculation of single-cell suspensions of transplantable *C3H* mammary carcinoma into *C3H* mice.

A more detailed report of these investigations will be published elsewhere in due course.

Possible Identity of 'Lactobacillin' with Hydrogen Peroxide produced by Lactobacilli

STRAINS of lactobacilli were recently isolated from Gruyère cheese which gave zones of inhibition against *Staphylococcus aureus* 20–30 mm. in diameter. This inhibition appeared to be antibiotic in nature, perhaps similar to that described by Grossowicz, Kaplan and Schneerson[1], and the active principle was called 'lactobacillin'[2]. The tests were done on agar buffered to *p*H 7·0 with 1 per cent phosphates to avoid false positive effects due to lactic acid[2,3]. Ritter has described similar experiments[4]. His strains were isolated in Switzerland from Emmenthal cheese and through his kindness they were included in this investigation. Most of our cultures have now been identified serologically by Dr. M. E. Sharpe as *Lactobacillus lactis*.

It was known from previous experience that inhibition observed on agar media needs to be confirmed by dilution assay, because toxic metabolic by-products are less likely to interfere with this type of assay[5]. The lactobacilli, which were initially cultured in milk, were therefore 'trained' to grow in a peptone–glucose medium supplemented with 'Tween 80' and malt extract. These culture fluids could not be sterilized without loss of activity, so that a dilution assay against *Staph. aureus* was devised by culturing the test organism in plain nutrient broth in which the lactobacilli failed to grow[2]. Average titres of 1/1,280 were obtained in these assays, and in similar assays against *Cl. butyricum* titres of 1/100 were frequently obtained.

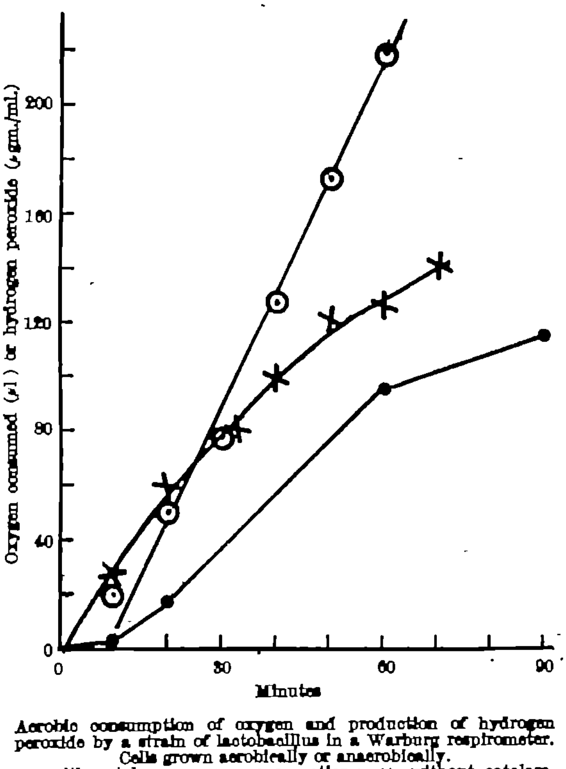
Hydrogen peroxide was not at first suspected. The culture fluids which were obtained in the malt extract medium were tested for the presence of hydrogen peroxide by a modification of the method of Main and Shinn[6]. In our hands, this method detected as little as 0·0002 per cent hydrogen peroxide (2·2 μgm./ml.). The sensitivity of *Staph. aureus* to hydrogen peroxide was given as 10 μgm./ml. by Coulthard *et al.*[7]; our test organism was slightly more susceptible, being inhibited by 4 μgm./ml. Moreover, when the assays were done in freshly boiled media and each tube was placed under a seal of alkaline pyrogallol, titres of about 1/640 were still obtained.

Two strains were then selected for further work in an endeavour to obtain the inhibitory substance free from cells. A wide range of organic and inorganic solvents at different *p*H's was used, but without success. Later, we attempted by physical and chemical means to disrupt the cells. Microscopic examination showed this to be very difficult; but whenever some measure of success was obtained the antibiotic activity was lost. It then became clear that the activity was always associated with living, though not necessarily multiplying, cells. In an experiment designed to check this point, the number of viable organisms was progressively decreased by alternate freezing and thawing at decreasing temperatures (refrigeration, solid carbon dioxide and liquid air). A parallel decrease in the assay titres was observed. It thus appeared that the cells produced the inhibitory substance, possibly hydrogen peroxide, during the assay.

Catalase prepared from *Micrococcus lysodeikticus* by the method of Herbert and Pinset[8] and a commercial pig liver preparation both abolished the antibiotic effect when 0·001 per cent was included in a dilution assay. However, catalase inactivated by adjusting to pH 2·5 and incubating at 42° C. for 2 hr. had no effect on the assay. Similarly, when catalase or fresh serum was included in the agar, no zones of inhibition were obtained. Pyruvate (0·01 per cent) also abolished the titre. In the 'anaerobic' assays which were done with tubes under a seal of alkaline-pyrogallol, all these substances were equally effective. It appears, therefore, that hydrogen peroxide is very readily produced by these strains of lactobacilli, even when only traces of oxygen are present. Hydrogen peroxide estimation in the actual assay tubes further confirmed these findings. In the last tube of these assays showing no growth, 4 μgm./ml. hydrogen peroxide was usually found, whether the assay was set up aerobically or 'anaerobically'. This figure agrees well with that previously found for the sensitivity of the test organism to hydrogen peroxide.

At this point all our strains were re-assayed by the dilution method against *Staph. aureus* with and without catalase in the medium. In all cases catalase abolished the inhibition.

It was still difficult to understand why the lactobacillus was some twenty-five times more resistant to hydrogen peroxide than the staphylococcus, being inhibited by 100–200 μgm./ml. As there is no catalase in lactobacilli, their much greater resistance could be attributed to destruction of hydrogen peroxide similar to that described by Seeley and Rio-Estrada with *Str. fæcalis*[9]. They found that aerated cultures of this organism developed a mechanism for utilization of hydrogen peroxide through riboflavin. In this case, however, we did not succeed in developing the adaptive mechanism, although in one series twenty-three consecutive sub-cultures were grown at 37° C. with vigorous shaking. When tested in a Warburg respirometer, the resting cells produced hydrogen peroxide from glucose whether they were grown on the shaker or under an anaerobic seal (see graph). In both cases catalase was stimulatory. At intervals estimations were made of the hydrogen peroxide in the contents of the Warburg flasks. In the absence of catalase, self-inhibitory levels of hydrogen peroxide (*c.* 120 μgm./ml.) were quickly reached and the rate of respiration declined. Further confirmation was obtained when hydrogen peroxide was added to resting cell suspensions and this was not decomposed. Finally, the sterile malt extract broth, but not other media, was found to contain an unidentified mechanism either for removing added hydrogen peroxide or masking the test. This explains the failure to find hydrogen peroxide in the culture fluids without affecting its presence in the assays, which were done in a simple nutrient broth.



Aerobic consumption of oxygen and production of hydrogen peroxide by a strain of lactobacillus in a Warburg respirometer. Cells grown aerobically or anaerobically.

○, with catalase, oxygen consumption; ×, without catalase, oxygen consumption; ●, hydrogen peroxide produced.

Each flask contained 0·8 ml. of a cell suspension, 1 ml. M/15 phosphate buffer (pH 7·0), 0·2 ml. of catalase (0·1 per cent) or 0·2 ml. distilled water. 0·2 ml. 5 N potassium hydroxide in centre well and 0·5 ml. M/10 glucose in side arm. Total volume, 2·7 ml.

It is possible that where these lactobacilli may naturally predominate, for example, in cheese, the hydrogen peroxide produced may have a beneficial effect. This part of the work is still in progress and full details will be published in due course. Meanwhile the evidence suggests that hydrogen peroxide is involved in the inhibitory mechanism and the name 'lactobacillin' is withdrawn.

Relationship between Reduced Glutathione Content and Spontaneous Hæmolysis in Shed Blood

Many enzymes contain sulphydryl groups essential to their activity; they are readily inactivated by oxidation. It is known that reduced glutathione protects them against oxidation[1]. In this respect hæmoglobin behaves in a similar manner to the 'SH-enzyme' in that its spontaneous oxidation to methæmoglobin is inhibited by glutathione[2].

It has been found that red cells in which all the hæmoglobin has been converted to methæmoglobin by sodium nitrite contain no reduced glutathione. When stored in the cold they hæmolyse spontaneously in apparently a shorter time than the normal cells[3]. These observations suggest that the hæmolysis of shed blood may be connected with methæmoglobin formation or with glutathione oxidation.

This communication gives an account of experiments which support the hypothesis that there is a relationship between the rate of spontaneous hæmolysis and the extent of oxidation of glutathione, and that this relationship is not influenced by methæmoglobin formation. The spontaneous hæmolysis was studied in samples of whole horse blood (pH 7·4–7·5) or in horse red blood cell suspensions in Ringer solution containing glucose (pH 7·0). The samples were exposed to air, or an oxygen and nitrogen–carbon dioxide (6 per cent) mixture, at 20° C. or at 37° C. during a period of time ranging between 1 hr. and 24 hr. The concentration of extra-cellular hæmoglobin (converted to cyanmethæmoglobin) was determined spectrophotometrically (at 540 mμ), at intervals of time. Parallel determinations of reduced and, in some experiments, total glutathione were made by Woodward and Fry's method[4].

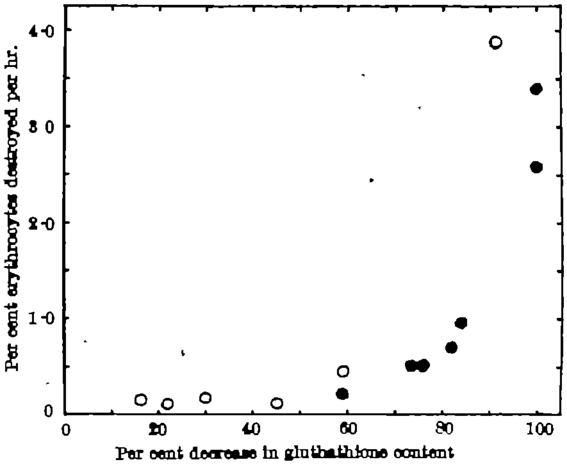
Blood exposed to oxygen for a period of time, ranging between 1 hr. and 6 hr., showed a more distinct hæmolysis than the blood exposed for the same period of time to air. The extent of hæmolysis in air or oxygen was increased on exposure to a temperature of 37° C. Under similar conditions, blood exposed to a nitrogen – carbon dioxide mixture showed no determinable concentration of free hæmoglobin.

In samples exposed to air or oxygen, the reduced glutathione gradually decreased during the period of observation, and the extent of its oxidation for the same period of observation was distinctly greater in samples exposed to oxygen. Exposure, for the same period of time, to air or oxygen at 37° C. produced a more marked decrease in the glutathione content than exposure at 18° C. In deoxygenated samples, the amount of glutathione present after exposure of 15 min. was greater than that in aerated or oxygenated samples and did not change with further exposure.

No significant change in the total glutathione was found in blood exposed to air, oxygen, or to a nitrogen – carbon dioxide mixture. The amount of methæmoglobin found at the end of an observation period did not exceed 3 per cent of the total hæmoglobin content.

Another series of experiments was carried out to determine whether the elimination of reduced glutathione by oxidation with iodine would increase the rate of spontaneous hæmolysis. It was found that: (*a*) no immediate hæmolysis was produced by the addition of iodine in final concentration of 0·6–6·0 μM in 1·0 ml. of blood or red blood cell suspension; (*b*) the decrease in glutathione content caused by iodine is related to the concentration of iodine added, and the glutathione reaches its lowest concentration (corresponding to the amount of iodine added) almost immediately after the addition of the iodine; (*c*) a complete oxidation of the glutathione could be achieved by the use of iodine, without any extensive formation of methæmoglobin (not more than 3 per cent of total hæmoglobin content); and (*d*) the rate of hæmolysis bears a certain relation to the extent of oxidation of the reduced glutathione.

The results of the six experiments in which iodine (solid circles) was used and the six experiments in which exposure to air or oxygen was employed (open circles) are given in the accompanying graph, in which the percentage decrease in reduced glutathione is plotted against the rate of hæmolysis determined from graphs.



The graph shows that there is no marked increase in the rate of hæmolysis until the glutathione content drops to about 40 per cent of its mean initial value, when a further decrease in glutathione content is connected with a rapidly growing rate of hæmolysis. This relationship applies to hæmolysis in blood exposed to oxygen as well as to the blood treated with iodine. This suggests that in both procedures the spontaneous hæmolysis has a similar mechanism.

The results of these experiments suggest that glutathione plays an important part in the maintenance of the integrity of the structure and function of the erythrocyte and, perhaps, of all tissue cells.

Improvements to the Melted Emulsion Technique of Autoradiography

THE method whereby autoradiograms are obtained by covering histological sections with photographic emulsion[1] has been improved or modified for specific needs[2-7]. In our laboratory, the inversion technique[3] has gained considerably in definition and ease of operations by substituting the emulsion from Kodak High Contrast Positive film for that of Matrix film (Eastman Kodak Co.) which contains a yellow dye.

The emulsion from Kodak High Contrast Positive film is unstained. It is removed easily from the base under the relatively bright Series 0*A* 'Yellow-Green Safelight'. It is very fluid at 38° C. and does not retain air bubbles. It can be processed and washed at the usual temperature (20° C.). It has a better resolution (165 lines per mm.); shows fewer background artefacts, and can be used for contact, for coating stained specimens[1,3,5], or for unstained sections which are inverted and stained after the photographic processing[3].

The technique at present in use for tracer studies of the mineralization of bones and teeth is as follows. For contact autoradiograms, strips of 35-mm. film are cut to appropriate size and placed in contact with the histological preparation, previously coated with 1 per cent celloidin in alcohol-ether. These are placed between two glass slides bound with cellulose tape and exposed in the dark at 4° C. After processing, the film strips are again bound between two glass slides with cellulose tape. This makes handling, storing, inspection and identification easy. In the melted emulsion technique, strips of 35-mm. film are cut to appropriate size (6–8 in.) and hydrated for a few seconds in distilled water, at room temperature. Each strip is then laid down on a glass plate, emulsion face up, and the emulsion is scraped from the central area with a glass slide. The emulsion is collected in a small beaker at 38° C. and, when melted, is picked up with a clean medicine dropper and transferred to the celloidin-coated microscope preparation. The practice of coating with a 'Blanchard brush'[3] has been altogether abandoned because it produces uneven coats and favours the production of air bubbles. The emulsion is then gelled and dried on a levelled glass plate, under a gentle air stream. The dry specimen is exposed in the dark at 4° C.

Development can be carried out at 20° C., but the cold bath (10° C.) for 10 min. gives less background fog and fewer artefacts. The formulæ *D*11 or *D*19, diluted 1 to 1 with distilled water at the time of use, give a more accurate picture than the previously used *D*72 ('Dektol').

The preparations are then rinsed in distilled water at 10° C., fixed for 10 min. in Kodak acid fixer with hardener also at 10° C. and finally washed under a gentle stream of tap water for 30 min. They can be dehydrated, cleared and mounted at this stage or inverted under water[3], remounted on a glass slide, section face up, and dried under a gentle air stream. For staining these inverted preparations, a 0·02 per cent aqueous solution of basic fuchsin is used, after passing through fresh oil of origanum and down-graded alcohol solutions to distilled water. Basic fuchsin solutions keep well and seem to gain strength when stored in glass-stoppered brown bottles; an older solution will stain well in 5 min., while a fresh one will require up to 10–15 min. Sections are transferred rapidly through 95 per cent alcohol, which differentiates and removes excess stain from the background. They are then passed through three baths of absolute alcohol. For clearing, oil of origanum is preferred to xylene or other light oils; it is messy but minimizes artefacts. Two baths are used and the preparations are finally mounted in 'Permount' (Fisher), using liberal amounts.

This work was carried out under a grant from the Advisory Committee on Medical Research of the National Research Council of Canada. The radio-elements were provided by the Council's establishment at Chalk River, Ontario.

Determination of Yeast Carbohydrates with the Anthrone Reagent

A PAPER on this subject by Fales[1] has recently appeared; almost simultaneously, we described a more extensive fractionation of yeast carbohydrates, using also the anthrone reagent for colorimetric determinations of total cell carbohydrate as well as of the individual fractions[2]. Considerable interest has been shown in this technique, as judged by the volume of correspondence we have received. As the original procedure was adapted to the small amounts of yeast used in manometric experiments on fermentation[3] and requires considerable manipulative skill and time, we wish to put on record the following adaptation which can be used when larger quantities of yeast are available for analysis. The dilutions of the various fractions are designed to give about the same optical density in the anthrone reaction as a standard solution containing 100 µgm. glucose/ml., when D.C.L. baker's yeast is used; other yeasts may require some adjustment in this respect.

The yeast to be analysed is suspended in water (50 mgm. wet weight/ml.).

Total carbohydrate: dilute to 1 mgm./ml. and determine as described[3].

Extracellular carbohydrate: centrifuge 10 ml. suspension (500 mgm.) and determine carbohydrate in the supernatant.

Acid-soluble carbohydrate (trehalose): suspend the residue in 3 ml. trichloroacetic acid (100 gm./lit.). After five minutes, transfer the suspension to a volumetric flask and make up to 50 ml. Mix, and stand for 5 min. Centrifuge 10 ml. (100 mgm. yeast) in a 15-ml. conical tube and determine trehalose on a 1 : 1 dilution of the supernatant. The residue from the alkaline extraction (see below) is not easily centrifuged, hence the use of the small conical centrifuge tube at this stage.

Alkali-extractable carbohydrate (mannan plus glycogen): wash the residue in the centrifuge tube with water twice. Suspend the washed acid-extracted cells in 1 ml. potassium hydroxide solution (300 gm./lit.) and heat 30 min. in a water-bath at 100° C. Cool, centrifuge, and pour the supernatant into a 10-ml. calibrated flask or cylinder: wash the residue by successive suspension in water and centrifuging, and make supernatant and washings to 10 ml. Dilute an aliquot 1 : 1 with water and determine mannan plus glycogen extractable by alkali.

Mannan: add 2 ml. Fehling's solution to 5 ml. of the alkali extract (≡ 50 mgm. yeast) contained in a 15-ml. conical centrifuge tube. Warm in the water-bath, and shake until the mannan copper complex is precipitated. After standing an hour or so, centrifuge and wash with dilute alkali (0·1 *N* sodium hydroxide). Dissolve the copper complex by adding sulphuric acid (few drops 10 *N* acid), transfer to a volumetric flask and make to 10 ml. When carrying out the colorimetric determination use two standards: glucose 100 µgm./ml., mannose 150 µgm./ml. in order to correct for the lower chromogenic value of mannose[4].

Acid-extractable polysaccharide (glycogen): suspend the residue from the alkali extraction in 2 ml. 2 *N* sulphuric acid, and heat 15 min. on the water-bath at 100° C. Cool and centrifuge; wash the residue with water, and make supernatant and washings to 15 ml. (6·67 mgm. yeast/ml.).

Glucan: add dropwise sulphuric acid (2 acid : 1 water) to the well-drained and chilled residue, stirring with a fine glass rod. As soon as the material dissolves, instantly dilute with a large volume of cold water, and transfer the milky fluid, making to 15 ml. with water (6·67 mgm. yeast/ml.).

It will be seen that the alcohol precipitation steps of the previous procedure[3] have been eliminated, saving time; and that the glucan is obtained in aqueous solution or fine suspension, which is more easily pipetted than the anthrone reagent used in the original method[2]. Results obtained by the two procedures are in agreement.

Note added in proof. A simpler method of treating the glucan precipitate is to add a few drops of potassium hydroxide solution (300 gm./lit.) and stir with a glass rod, when the glucan disperses and can be diluted to give a stable suspension suitable for direct pipetting.

Refection in the Common Shrew

REFECTION or 'coprophagy' has been observed in the rabbit[1] and in certain other rodents, including the house-mouse and brown rat[2]; but there appear to be no records of its occurrence in the Insectivora. The habit has now been observed in juveniles and adults of both sexes of the common shrew, *Sorex araneus* Linn.

The animal adopts a curled-up position upon its side or back, within the nest, parts the hind-limbs and begins to lick the anus. Some individuals grip the hind-limbs with the forefeet in order to maintain this attitude. After a few seconds a rapid series of abdominal contractions brings about the gradual eversion of the rectum. It emerges as a stout firm tube, 5–10 mm. long, which curves slightly forward towards the mouth. The open end of the everted rectum is nibbled and licked for a period which has not been observed to exceed ten minutes. Inversion into the body, like eversion, is effected by abdominal movements. If the animal is picked up without warning, the everted rectum may lose its 'erected' condition and become flaccid.

When the animals are dissected immediately after refection, the stomach and the first few centimetres of the intestine are found to be filled with a milky fluid containing numerous fat globules and small fragments of undigested food. The remainder of the intestine and the rectum are completely empty. It is evident that refection does not commence until the gut is entirely free of fæcal matter. Possibly the brief anal lickings frequently observed prior to refection are directed towards sampling the rectal contents.

Harder[2] reviews present knowledge of refection in rodents, and proposes the term 'cæcotrophy' to replace 'coprophagy', in view of the cæcal origin of the ingested material. While refection in the shrew may imply analogous nutritional consequences, the mechanism involved must be quite different as no cæcum is present. The process may be a relatively simple one, brought about by a periodic cessation in the flow of digestive fluids. Its occurrence in recently weaned juveniles and in adults soon after capture suggests that it is a normal physiological process rather than one occasioned by diet deficiency in captivity.

These observations were made while engaged on an ecological study of the species at the Bureau of Animal Population, Department of Zoological Field Studies, University of Oxford.

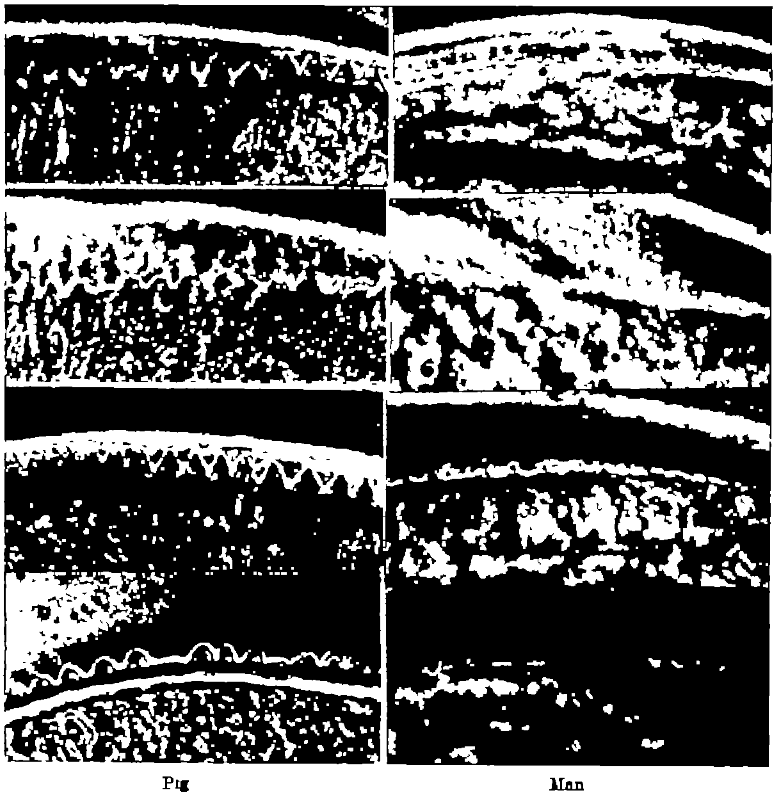
Anatomical Distinction between Human and Pig Strains of *Ascaris*

IT has long been a matter of uncertainty whether the ascaris parasite of the domestic pig is specifically identical with *Ascaris lumbricoides* L. 1758 from the



Denticles of *Ascaris* of pig and man. × 750 intestine of man. The evidence, as brought forward by epidemiological observations and by experimental infections, appears on the whole to indicate that there is a difference in these two parasites; but no morphological feature has been discovered which distinguishes them as separate species.

Through the kind co-operation of Dr. P. C. Beaver, of Tulane University, U.S.A., I have recently examined, while working at the Ontario Research Foundation, about fifty well-preserved specimens of the human ascaris removed from the intestine of a child at operation. The denticles of the dentigerous ridges were compared with those of the pig ascaris obtained from an abattoir in Toronto. Comparisons were made of *en face* and internal views of the lips both in the glycerine- and creosote-cleared specimens. Both sexes were examined in about equal numbers.

The photographs (reproduced herewith) show that the denticles of the pig ascaris (Figs. 1–4) form a conspicuous row of more-or-less equilateral triangles and that the edges of the denticles are straight. In contrast, the denticles of the human ascaris are considerably less conspicuous, being smaller and having concave edges (Figs. 5–8). In some specimens of the pig ascaris the points of the denticles are rounded, possibly by wear, but the difference is still apparent (Figs. 2 and 4). In some specimens of the human ascaris, the denticles appear to be worn away, only the ridge being evident.

The purpose of this communication is to suggest that specimens from other parts of the world should be examined with regard to their denticles, so that the taxonomic value of these structures may be ascertained.

I should be grateful to receive any ascaris material.

An Improved Electrophoresis Cell for the Analyses of Several Sera Simultaneously

AN electrophoresis cell which enabled two sera to be analysed simultaneously was described in a previous communication[1]. In this apparatus two 'Cellophane' membranes were inserted between the top and the bottom of the standard analytical cell and the electrode vessels.

A new apparatus embodying the same principle but giving diagrams identical with those obtained by the conventional method is depicted in Fig. 1. *A* and *B* are 'Perspex' adaptors connected to the electrode vessels, *C* is the central part of a standard Longsworth cell and *D* is a slotted 'Perspex' slide which can cut off communication between *A* and the cell when desired. Prior to assembly, the ground surfaces of the 'Perspex' and glass are well greased and a 'Cellophane' membrane *M* is clamped between *B* and the cell *C*. The balance of the apparatus is then assembled and the sera to be analysed introduced via the slots in the bottom of adaptor *A* and the levelling section. The levelling section is then moved to the cut-off position, the excess serum removed and the rest of the cell filled with buffer and a saturated solution of potassium chloride.

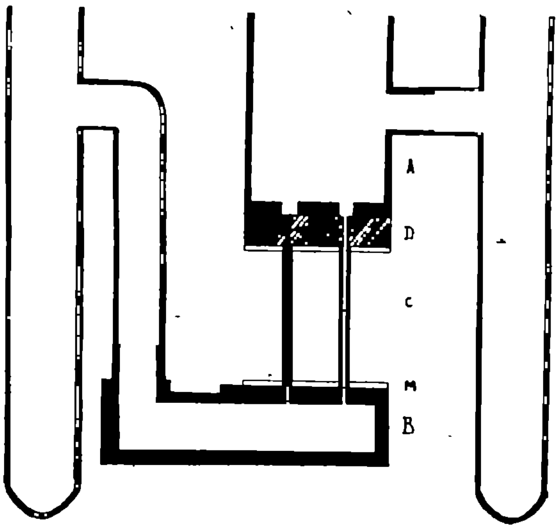

Fig 1 Electrophoresis cell. The two electrode vessels are connected via the adaptors *A* and *B* to the standard Longsworth cell *C*. *D* is a 'Perspex' slide which can cut off communication between *A* and *C*. *M* is a 'Cellophane' membrane clamped between *C* and *B*

After temperature equilibrium has been established in the electrophoresis bath, a fine Pasteur pipette with its tip bent horizontally is lowered, through chamber *A* and the slots in the levelling section, into the cell, and fluid is drawn off at the required level. A very sharp interface is thus established at this position between the serum and the buffer. This method of boundary sharpening has previously been used in electrophoresis and diffusion measurements[2,3]. The current is now switched on and electrophoresis performed in the usual way.

As mentioned in the previous communication[1], there is no theoretical limit to the number of compartments which can be introduced into the analytical section, and consequently to the number of analyses which can be performed simultaneously.

Electrophoresis diagrams obtained with the new apparatus are shown in Figs. 2,*a* and *b*. Fig. 2,*a* is the diagram of normal serum and is free from the anomaly found in diagrams made with the earlier form of the apparatus. Fig. 2,*b* shows diagrams of

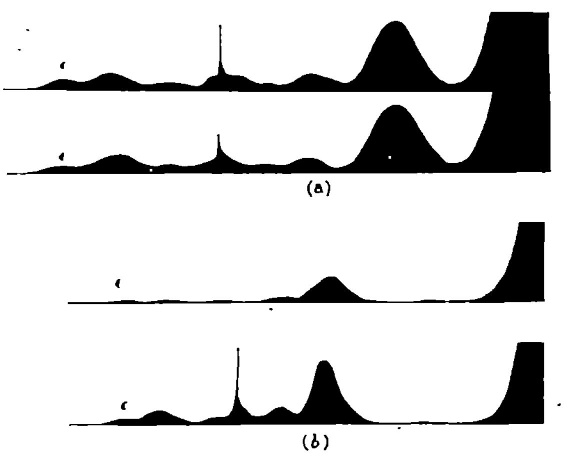

Fig. 2 (*a*) Two electrophoresis diagrams of the same serum run simultaneously in the two limbs.
(*b*) Electrophoresis diagrams of the serum and urine of a patient with orthostatic albuminuria run simultaneously The urine was concentrated eight times before electrophoresis

the serum and urine of a patient with orthostatic albuminurea.

An electrophoresis cell is now under construction which will allow four electrophoretic analyses to be performed simultaneously. With this type of cell the sera may be removed by a long pipette after a run and immediately replaced by a second batch of four samples. In this way we hope to be able to analyse at least eight sera during the course of a normal working day.

The Virus Research Unit in which this work was carried out is financed by the South African Council for Scientific and Industrial Research with additional grants from the Nkana-Kitwe and Chingola Poliomyelitis Research Funds.

Structure of White Phosphorus : Single Crystal X-Ray Examination

SEVERAL attempts to obtain X-ray diffraction patterns of crystalline white phosphorus have been made[1]. It is claimed by some that the ready reversion of the white to the red form under irradiation with X-rays prevents any pattern being obtained, while others suggest that the high degree of thermal motion in the crystal lattice will render it impossible to obtain anything but a few very diffuse rings. Natta and Passerini[2], however, state that they obtained a well-defined powder photograph of white phosphorus with 22 lines, using iron $K\alpha$ radiation at − 35° C. They claim that the substance is cubic with $[a] = 7 \cdot 17$ A., containing four molecules of P_4 per unit cell, but give no other data.

By using copper $K\alpha$ radiation at − 30° C., we have obtained X-ray diffraction patterns from single crystals of white phosphorus. Our results do not confirm those of Natta and Passerini. Sticks of highly purified white phosphorus were sealed in glass tubes under vacuum and crystals grown by slow sublimation. A wide variety of crystalline habit was observed. Needles, rectangular plates and various polyhedra were obtained, all of which gave similar X-ray patterns. It was found that these single crystals would remain stable, usually for two or three days, if they were given a thin coating of methanol–shellac solution. The crystals were cooled in a stream of dried air at − 30° to − 35° C. during exposure, and well-defined oscillation and rotation photographs were obtained on a standard camera of 3 cm. radius. Attempts to obtain powder photographs using Natta and Passerini's technique[2] were unsuccessful.

The X-ray photographs indicated a body-centred cubic lattice with $[a] = 18 \cdot 51 \pm 0 \cdot 03$ A. Systematic absences of the reflexions were $\{hkl\}$ when $\{h+k+l\}$ was odd. A Laue photograph revealed the presence of a fourfold axis of symmetry, and this meant the space group was probably $I432$, $I\bar{4}3m$ or $Im3m$. The crystal density at − 25° C. was found to be 1·84 gm./c.c. A unit cell containing 56 P_4 molecules gave a calculated density of 1·82 gm./c.c. The general features of the photographs included, in addition to single crystal spots, weaker diffuse rings corresponding to spacings of roughly 4·3, 2·5 and 1·7 A. Evidence for a high degree of thermal motion in the structure was afforded by the very rapid decrease of the intensities of the diffraction spots after a value of about $\rho = 1 \cdot 0$.

It is reasonable to suppose that the structure is built out of discrete tetrahedra similar to those which exist in the vapour[3], with $P - P = 2 \cdot 21 \pm 0 \cdot 02$ A. and angles $P/P/P = 60°$. Preliminary structural studies with the aid of similar tetrahedral models indicated that 56 P_4 molecules could not be arranged in the unit cell without appreciable mutual overlap, if the non-bonded radius of the phosphorus atom was taken[4] to be 1·9 A. An explanation of the structure may be found in some peculiar effect of the thermal motion on the packing arrangements. Space group $Im3m$ could be rejected as very improbable on general crystallographic grounds, and $I\bar{4}3m$ seemed a more likely choice than $I432$. Further examination of the crystal structure is proceeding and detailed results will be published elsewhere.

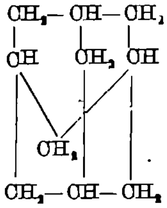
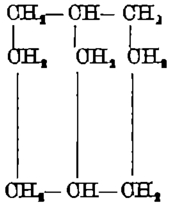
Thiaadamantane

THE investigation into the composition of the sulphur bodies present in the kerosene boiling-range of a Middle East crude oil distillate (Agha Jari, South Iran) has indicated that the sulphuric acid-soluble neutral compounds consist mainly of fully hydrogenated mono- and bi-cyclic sulphides with smaller amounts of alkylated thiophenes. A solid sulphur-containing compound is also present which collects as a sublimate in the column head during the fractionation when the column head reaches 78° C. at 3 mm. mercury pressure. This solid can be purified by sublimation or recrystallization, and forms sweet-smelling crystals which melt in a sealed tube at 320° C. with decomposition. Analysis gives the empirical formula $C_9H_{14}S$.

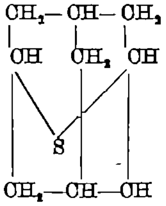
The general character of this interesting compound together with its chemical reactions, which include the formation of a sulphone and a mercuric chloride complex, suggests that it is a doubly bridged *cyclo*-paraffin in which a sulphur atom forms one bridge. In its physical properties this compound resembles the hydrocarbon adamantane isolated by Landa and Macháček from a Hodonin naphtha[1]. The structure of this hydrocarbon, confirmed by synthesis (Prelog and Seiwerth[2]), is that of a doubly bridged *cyclo*-octane ring (I). Confirmation that our sulphur body contains a basic structure resembling that of adamantane is shown by the fact that, on desulphur-



(I)



(II)



(III)

ization with Raney nickel, it yields *bicyclo*-1.3.3-nonane (II).

While it is possible that the sulphur occupies alternative positions in the adamantane structure and that desulphurization still yields the same *bicyclo*nonane, from the general character of our compound it appears highly probable that the sulphur forms the second bridge spanning the 3.7-carbon atoms (III). An attempt is being made to confirm this structure by synthesis. The isolation of this compound together with that of the bicyclic sulphides and thiophenes which accompany it will be fully reported in due course elsewhere.

Reduction of Tropinone with Lithium Aluminium Hydride

The reduction of the keto group in tropinone (I) to the secondary alcoholic stage gives the two internally compensated stereoisomerides tropine and ψ-tropine (II). The nature of the reduction product depends on the reducing agent used. When the reduction is done electrolytically or with zinc and hydriodic acid, tropine is the main product[1]. However, the reduction product is always contaminated with small amounts of ψ-tropine. With sodium amalgam tropinone is reduced to ψ-tropine only[1]. As the formation of tropine and ψ-tropine from tropinone involves the reduction of a ketone to a secondary alcohol, it could be foreseen that lithium aluminium hydride would be a specific reagent for it[2]. However, the interest lay in knowing the exact nature of the reduction product (or products) obtained.

Reduction of tropinone was studied in ether solutions. In all the experiments ψ-tropine was obtained and the yield was quantitative. Difference in the concentration of the solution, in the rate of addition, or reverse addition, made no change in the nature of the reduction product. A range of temperatures from −10° to the boiling point of ether made no difference. In all the experiments, the product was isolated in the form of the picrate to ensure the separation of tropine and ψ-tropine[1,3].

A New Province of Igneous Ring-Complexes in Southern Nyasaland

Recent examination of air photographs of Southern Nyasaland taken by the Royal Air Force has revealed that almost certainly this area forms a province of igneous ring-complexes, vents and dykes comparable with the British Tertiary igneous area of West Scotland, the White Hart Mountains region of New Hampshire and the more recently described region of ring intrusions in Nigeria. Indeed, it seems probable that the number of vents and ring-complexes in Southern Nyasaland and the adjoining parts of Portuguese territory will exceed that of any previously reported area.

From Dr. F. Dixey's work[1] on the Nyasaland Geological Survey, it has long been known that vents filled with agglomerates and the much-discussed carbonatites exist in the region of Lake Chilwa, and it now appears likely that these form one manifestation in a complete igneous episode involving, in order of time, great outpourings of lava, the explosion of volcanic vents, probable cauldron-subsidence and the intrusion of ring-dykes and great syenite stocks and, lastly, the injection of basic dykes. The Stormberg period at the close of Karroo times was characterized by the extrusion of tremendous lava flows over a very large area in Central and South Africa, and Dr. Dixey has been able to date the volcanic vents of Southern Nyasaland as being post-Karroo and pre-Cretaceous. Further, it is known that the nepheline syenite intrusions into the vents are later than the agglomerates and carbonatites and, while the great ring-dyke complexes now reported have not yet been dated, there is very good reason to suppose, from analogy with other areas, that they follow on, in time, after the explosive vents and were themselves followed by the dyking phase.

One very spectacular ring-dyke complex forms Chambe Plateau in the north-western part of the Mlanje Mountains; it is thought to comprise four successive ring-dykes about the same centre and with a common vertical axis. The external diameter of the outermost dyke is just over four miles. From the plains at the foot of the mountains the two outer 'rings' rise almost sheer for 6,000 ft. in places, while the two inner 'rings' form a central circular depressed region some 2,000–2,500 ft. below the outer 'rampart'.

The facts observed on the photographs and the hypotheses formed therefrom must, of course, be checked in the field before this potentially important region can be discussed in detail; but the recognition of the ring complexes and dykes from air photographs forms a striking example of the value of photogeological interpretation. Work on the photographs continues at the headquarters of the Directorate of Colonial Geological Surveys.

Rapid Estimation of Standard Deviations

WHEN a series of numbers can legitimately be regarded as random samples from a normal distribution, the mean range within small sub-groups, multiplied by a factor depending only on group-size, gives a very good and easily calculated estimate of the standard deviation of the parent distribution, not much inferior in precision to that obtainable from the mean squared deviation[1]. A specially simple computation is obtained when the sub-group size is two.

Let the successive individual readings be A, B, C . . . X, Y, Z. The sum is required of all the ranges between adjacent numbers. This means that all the differences, $(A - B)$, $(B - C)$, and so on, are to be given a positive sign and added together. If B is greater than both A and C, it will have a positive sign twice. If B is less than both A and C, it will have a negative sign twice. But if B is bigger than one neighbour and smaller than the other, it will take one positive sign and one negative sign, and so will cancel out. The sum of the sub-group ranges, therefore, is twice the sum of the peak numbers (bigger than both neighbours) minus twice the sum of the trough numbers (smaller than both [illegible]ou[illegible]s). This rule obviously breaks down for
[illegible]al numbers A and Z. To deal with this,
[illegible] series as an endless cycle, going back to
[illegible]aching Z, and write the first two numbers
[illegible]he end, thus : X, Y, Z, A, B. It is then
[illegible] see whether Z and A are peaks, troughs
[illegible]liate, and to add, subtract or ignore them
[illegible]. When two or more adjacent numbers
[illegible]l, disregard all except the first and treat
[illegible] regular rule. If there are N items in
[illegible]here are also this number of sub-ranges.
[illegible]or converting range into standard devia-
[illegible]ry groups is 0·886, which can be taken
[illegible]hs. Hence the following rule :

[illegible]te the standard deviation of a random
[illegible]a normal distribution, add all the peak
[illegible]d subtract all trough numbers in the
[illegible]the first two members repeated at the
[illegible]by $\frac{1}{2}N$, and take off one-ninth.

[illegible]-minus-trough values can usually be
[illegible]lly, and may be written down and added.
[illegible]ne, the peak and trough totals can be
[illegible]taneously, and the difference between
[illegible]en be obtained.

[illegible]thods for standard deviation have been
[illegible]ntinue to give quite good approximations
[illegible]the distribution differs markedly from
[illegible] But the estimate may be seriously dis-
[illegible] data are not in random order. Any
[illegible]d, whether upwards, downwards or cyclical, or any circumstance which causes adjacent values to be more closely alike or more unlike than would happen by chance, will produce bias in the estimate. In doubtful cases, there is a useful simple test of randomness. For large N, the number of peaks (or troughs) in a random series may be regarded[2] as normally distributed with mean $N/3$ and standard deviation $(N/22\frac{1}{2})^{1/2}$. The difference between actual and expected number of peaks is tested for significance in the usual way. If the discrepancy is D, there is no evidence, at the 95 per cent probability-level. of departure from randomness so long as D^2 is not larger than $N/5{\cdot}86$, or, to a sufficient approximation, not larger than $N/6$. When there are many 'ties' between adjacent observations, the number of these should be subtracted from N before the test for randomness is applied.

In practice, moderate departures from randomness do not invalidate the estimate of standard deviation, provided this method is recognized as giving only a quick approximation. It will often suffice to settle questions of significance without need for recourse to the maximally efficient but much more laborious computation based on sums of squares. It may also be used as an independent check of standard deviations calculated in the orthodox way. If this is done, the computer will soon gain experience of the effect of departure from randomness on the estimate of standard deviation. When the departure from randomness is serious, the method may still be applicable provided it is not difficult to shuffle the data so as to get nearer a chance order. It may suffice, for example, to read the data across rows instead of down columns. The method is specially useful for data recorded on control charts. It can also be used to get a pooled estimate from sets of observations presumed to have the same standard deviation though their means may differ, such as arise in biological assay. The peak-minus-trough figures are totalled over all the series, and treated as if they came from one series with ΣN observations.

To obtain the mean, make a separate total of the intermediate numbers (neither peak nor trough) and add to the peak and trough sums to get the grand total. All three totals can be computed simultaneously on the usual kinds of machine. An easier method, which gives the mean and a rather less precise estimate of the standard deviation, is to take the observations in non-overlapping pairs and to add separately the larger and the smaller numbers. Thus A and B would first be considered, then C and D, and so on, the smaller of each pair being accumulated on the left, and the larger on the right, of the machine. If N is even, the sum of the totals divided by N gives the mean, and the difference, divided by $\frac{1}{2}N$ with one-ninth deducted, gives the estimate of the standard deviation. If N is odd, the last observation may be omitted for computation of the standard deviation, or it may be paired with the first, the divisors being respectively $\frac{1}{2}(N - 1)$ or $\frac{1}{2}(N + 1)$. For computing the mean, every observation is, of course, taken once.

The methods described above are specially rapid on key-driven adding machines.

FORTHCOMING EVENTS

(*Meetings marked with an asterisk * are open to the public*)

Monday, October 13

University of London (in the Physiology Theatre, University College, Gower Street, London, W.C.1), at 4.45 p.m.—Prof. Adrien Albert: "Ionisation and Biological Activity".* (Further Lectures on October 20 and 27.)

Physical Society, Acoustics Group (in the Lecture Theatre, Science Museum, Exhibition Road, London, S.W.7), at 5 p.m.—Mr. A. T. Pickles: "Acoustics in America".

British Society for the History of Science, Philosophy of Science Group (in the Joint Staff Common Room, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Dr. D. Mackay: "An Artefact's Approximation to Voluntary Behaviour".

University of London (at King's College, Strand, London, W.C.2), at 5.30 p.m.—Prof. E. M. Landis: "Movement of Fluid and Dissolved Substances through the Capillary Wall", 1.* (Further Lectures on October 15 and 17.)

University of London (in the Botany Department Lecture Theatre, Imperial College of Science and Technology, Prince Consort Road, London, S.W.7), at 5.30 p.m.—Prof. G. Melchers: "Physiology of Flower Formation".* (Further Lectures on October 15 and 17.)

Society of Chemical Industry, Fine Chemicals Group (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 7 p.m.—Prof. F. E. King: "Synthesis of Simple Peptides".

Tuesday, October 14

University of London (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 1.15 p.m.—Dr. A. Armitage: "Copernicus and the Reformation of Astronomy".*

Zoological Society of London (at the Zoological Gardens, Regent's Park, London, N.W.8), at 5 p.m.—Scientific Papers.

Institution of Chemical Engineers (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Prof. D. M. Newitt, F.R.S., Dr. J. F. Richardson, Dr. R. H. Clark and Mr. D. H. Charles: "Pneumatic Conveying, Part 1, The Pressure Drop during Horizontal Conveyance".

Illuminating Engineering Society (at the Royal Institution, 21 Albemarle Street, London, W.1), at 6 p.m.—Dr. W. J. Wellwood Ferguson: Presidential Address.

Institution of Electrical Engineers, Education Discussion Circle (at Savoy Place, Victoria Embankment, London, W.C.2), at 6 p.m.—Discussion on "The Teaching of Chemistry to Engineers" (to be opened by Dr. J. E. Garside).

Wednesday, October 15

Royal Sanitary Institute (at 90 Buckingham Palace Road, London, S.W.1), at 2.30 p.m.—Mr. W. F. B. Shaw: "The Efficiency of Domestic Solid-Fuel Appliances".

Physical Society, Colour Group (at the Institute of Ophthalmology, Judd Street, London, W.C.1), at 3.30 p.m.—Dr. E. N. Willmer: "Central Foveal Colour Vision": Mr. R. A. Weale: "Colour Vision in Extrafoveal Regions".

Geological Society of London (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Prof. Howel Williams: "Progress and Problems in Volcanology" (William Smith Lecture).

Royal Society of Medicine, Comparative Medicine Section (at 1 Wimpole Street, London, W.1), at 5 p.m.—Dr. O. L. Oakley: "The Sites of Production of Antibodies" (Presidential Address).

Textile Institute, Lancashire Section (joint meeting with the Newcomen Society, at the Textile Institute, Manchester), at 6.30 p.m.—Mr. W. A. Hunter: "James Hargreaves and the Invention of the Spinning Jenny".

Thursday, October 16

University of London (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 1.15 p.m.—Dr. Helen Spurway: "Is Man a Domestic Animal?"*

Society of Chemical Industry, Microbiology Group (at the Medical Society of London, 11 Chandos Street, Cavendish Square, London, W.1), at 2.30 p.m.—Mr. H. Proom and Dr. A. J. Woiwod: "The Application of Paper Chromatography to Microbiology".

Institution of Mining and Metallurgy (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Mr. J. B. Richardson. "Graduates in Metal Mining—Notes on their Status, Training and Vocation"; Mr. R. S. Cooke: "Recovering a Flooded Shaft in the O.F.S. Goldfield".

Physical Society, Low-Temperature Group (in the Lecture Theatre, Science Museum, Exhibition Road, London, S.W.7), at 5.30 p.m.—Dr. A. J. Barnard: "Gas Compressors".

Society of Chemical Industry, Road and Building Materials Group (at the Building Centre, Store Street, London, W.C.1), at 6 p.m.—Dr. A. C. Whiffin and Mr. W. I. J. Price: "Road Problems arising from Snow and Ice".

Royal Institute of Chemistry, London and South-Eastern Counties Section (joint meeting with the Institute of Biology and the London and Home Counties Branch of the Institute of Physics, at the City of London School, Victoria Embankment, London, E.C.4), at 6.30 p.m.—Discussion on "The Place of the Scientist in Civil Defence".

Chemical Society (at Burlington House, Piccadilly, London, W.1), at 7.30 p.m.—Dr. D. H. R. Barton: "The Stereochemistry of *cyclo*-Hexane Derivatives" (Tilden Lecture).

British Institute of Radiology (in the Reid-Knox Hall, 32 Welbeck Street, London, W.1), at 8 p.m.—Mr. J. W. McLaren: "Some Aspects of Soft Tissue Radiography" (Presidential Address).

Friday, October 17

British Mycological Society (in the Physics Lecture Theatre, Birkbeck College, Malet Street, London, W.C.1), at 10.45 a.m.—Papers on "The Physiology of the Host-Parasite Relationship in Fungi and Bacteria".

Institute of Navigation (at the Royal Geographical Society, 1 Kensington Gore, London, S.W.7), at 3 p.m.—Annual General Meeting; Rear-Admiral A. Day: "Navigation and Hydrography" (Presidential Address).

University of London (in the Chemistry Department, University College, Gower Street, London, W.C.1), at 4.30 p.m.—Seminar on "Polymer Science".* (Further Lectures on October 24, 31, November 7, 14, 21, 28, and December 5.)

Institution of Mechanical Engineers (at Storey's Gate, St. James's Park, London, S.W.1), at 5.30 p.m.—Sir David Pye, F.R.S.: "The Art of the Practical Engineer" (Presidential Address).

Royal Institute of Philosophy (at University Hall, 14 Gordon Square, London, W.C.1), at 5.30 p.m.—Prof. J. Z. Young, F.R.S.: "Mind and its Place in Nature" (Manson Lectures, 1). (Further Lectures on October 24 and 31, November 7, 14 and 21.)

Institute of Physics, Industrial Radiology Group (at 47 Belgrave Square, London, S.W.1), at 6.30 p.m.—Dr. L. Mullins: "The Physics of the Radiographic Image".

World Calendar Association, British Section (at the Royal Society of Arts, John Adam Street, Adelphi, London, W.C.2), at 7.30 p.m.—Sir Harold Spencer Jones, F.R.S.: "The Calendar—Past, Present and Future".* (Admission by ticket from 20 Buckingham Street, London, W.C.2.)

Saturday, October 18

Nutrition Society (at Bedford College, Regent's Park, London, N.W.1), at 10.15 a.m.—Conference on "Unusual Foods for Human Consumption".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned.

Honours Graduate (first- or good second-class) for cytogenetical research on tuberous species of Solanums, and an Assistant Experimental Officer (woman) for investigations of Late Blight and general maintenance of potato collection, at the Potato Genetics Station, Cambridge—The Secretary, Agricultural Research Council, 15 Regent Street, London, S.W.1 (October 17).

Assistant Lecturer in Electrical Engineering, to teach light current electrical engineering to H.N.C. and, possibly, final B.Sc standard—The Principal, Royal Aircraft Establishment Technica
College, Farnborough, Hants (October 18).

Experimental Officer to undertake research work connected witl
the application of strain gauge techniques to agricultural engineerin
problems, and in particular, to investigate with the aid of mobil
strain recording equipment the dynamic forces within implements an
tractors working on hillsides—The Secretary, Scottish Machiner
Testing Station, Howden, Mid Calder, Midlothian (October 18).

Principal Lecturer in Electrical Engineering—The Regi
trar, Military College of Science, Shrivenham, Swindon, Wilts (Oct
ber 18).

Head of the Department of Biology—The Princi pal,
Polytechnic, Manresa Road, London, S.W.3 (October

Pathologist at the Equine Research Station, Ne
Pathologist at the Canine Research Station, near Ne
Pathologist at the Poultry Research Station, St. Ives,
